 Anchusa italica, 224
 Anglesey Industry Association, 130
 Annals, some neglected, 245
 Anthracite coal for greenhouses, 335
 Anthuriums as garden plants, 180
 Apiary, the, 9, 49, 68, 109, 127, 215, 230, 295
 Apple crop, the, 186; weevil, to destroy, 156
 Apples: Cox's Orange Pippin, origin of, 454; Beauty of Hants, 345, 367, 388; Ben's Red, 219; Feltham Beauty, 178; Jolly Beggar, 388; Red Victoria, 298; Renown, 293; Ribston Pippin, history of, 454
 Arachnæthe moschiferæ flowering in Messrs. Sanders' nursery, 179
 Aralia (see also Fatsia), 144; A. Veitchii, grafting, 24, 104
 Arctostaphylos manzanita, 163
 Asplenium tuberosum in America, 169
 Asperula hirta (Ramonda's variety), 63
 Aster "Climax," 308
 Attar of Roses, 449
 Auricula, history and culture of the, 277
 Austria, denirological society in, 12
 Autumn effect of trees and shrubs, 209; flowers, 137
 Avenue tree, the Larch as an, 82
 Avocado-Fear, the, 443

B

BALDERSBY PARK, Thirsk, 113
 Banana-culture in North Queensland, 385
 Bananas, fibre from, 413
 Bank plants and flower shows, 313
 Bank, plants for a moist, 156; for a dry, 335
 Bankruptcy statistics, 168
 Barbados, cotton cultivation in, 46
 Bartholma pectinata, 42
 Bateson, W. (*The Methods and Scope of Genetics*), 409

Battersea Park, Chrysanthemums in, 308; flower gardening in, 72
 Bawdsey Manor, Felixstowe, 406
 Bayham Abbey, Tunbridge Wells, 170
 Bean, W. J. (*The Royal Botanic Gardens, Kew*), 328
 Beckett, Edwin (*Vegetables for Home and Exhibition*), 3
 Beech cocoon, the, 257
 Beekeeping, 9, 49, 68, 109, 127, 215, 230, 295
 Begonia (Clibran's Pink, 357; B. Glorie de Lorraine, female flowers of, 204
 Belgian railway stations and flowers, 11
 Belgrove, Co. Cork, 424
 Benevolent Institution, Gardeners' Royal, 10, 280, 263, 432
 Benthama fragifera in Hampshire, 546; fruiting in Sussex, 417
 Bequests to gardeners, 167
 Berlin botanical garden, 31; International Show, 1909, 104, 313
 Bird-scaring devices, 81
 Birds, trapping, 74
 Black Currant attacked with Gooseberry disease, 203
 Black Currant x Gooseberry hybrid, 120
 Black, John, long service of, 345
 Black-scab disease of Potato, 218, 375, 449
 Bleekrodeæ sp., a new rubber-producing tree, 12
 Board of Agriculture intelligence division, 432

BOOKS, NOTICES OF:—Alpines and Bog Plants (*Revised Edition*), 409; A Practical Guide to School, Cottage, and Allotment Gardening (*John Watters*), 203; Beautiful Flowers and How to Grow Them (*Walter J. Wicherley*), 50
 Boromas, the, 24
 Botanical collection, the late Sir Dietrich Brandis', 167
 Botanic garden at British Honduras, 31; in the Swiss mountains, 216

Botany lectures at Aberdeen, 51
 Borage, fruits and vegetables, an exhibition of, 51, 147
 Bourn, W. P., retirement of, 186
 Bourg St. Pierre, Jardin de Linnaea at, 216
 Bowling green, how to make a, 176
 Box, Dallimore on the, 450
 Brachyglottis repanda, 52
 Bradshaw collection of Orchids, sale of the, 329
 Brandis, the late Sir Dietrich, Brassia insularis of, 167
 Brassia insularis, 167
 Brasso-Laha Rosslyn in Mr. Pitt's collection, 291
 Brazil Nut, the, 444
 Bread fruit, the, 445
 Brine as a preservative for fruits, 112
 Briti-bulb growers in Holland, 282
 British Columbia, exhibition of fruit from, 433; fruit growing in, 251
 British Honduras, proposed botanic garden at, 31
 Brown, E. P. (*Illustrated Poultry Record*), 266
 Brown, Mr. K., appointment of, 92
 Bulb growing, 245; at Portmadoc, 249; in Holland, 243, 282; in the Marshlands, 162
 Bulbophyllum lemniscatoides at Gattop Park, 323
 Bulbophyllum vires ens, 388
 Bulbs, the forcing of, 402; forthcoming exhibition of, 146
 Burnham Beeches, decay of the old trees at, 114
 Burvenich, Mons. Fred., testimonial presented to, 131
 Butterflies, flowers visited by, 304

C

CALATHIUMS as garden plants, 63
 Calderbank, Arthur, appointment of, 130
 Campanula carpatuca var. pelvi-formis, 64
 Campanula Raddeana, 139
 Camphor trade, the future of the, 280
 Canada, fruit crop in, 46
 Cane, Florence du (*The Flowers and Gardens of Japan*), 325
 Carbolic acid as a curative for Seakale disease, 189
 Carnation and Picotee, the, 212; seedling of the, 201
 Carnation exhibition in December, 379
 Carnation Winter Cheer as a bedding plant, 330
 Carnations in America, three good bedding, 111
 Carpentaria californica at Oakley, Hants., 112
 Carrots, cultural note on, 103
 Cashew Nut, the, 444
 Catalpa bignonioides at Westonbirt, Gloucestershire, 11, 313
 Catasetum Clavianum, 211
 Catasetums at Kew, 211
 Caterpillar of the winter moth, 32
 Cattleyas as cut flowers, 106
 Cattleya Veana, 258; C. Warscewiczii at Orkneys, 4
 Cavanagh, B. Francis, 330
 Cedrus Deodara and a rockery, 172
 Celery, two desirable varieties of, 103
 Cemetery superintendents in America, 186

CERTIFICATED FRUITS AND VEGETABLES:

Apples: Encore 453; Feltham Beauty, 150; Red Victoria, 221; William Crump, 453
 Beets: Blood Red, 255; Willow-leaved, 255; Pineapple, 255; Sutton's Crimson Globe, 117; Blackberry x Loganberry Low Junior, 37; Cabbages: All Heart, 205; Autumn Exhibition, 205; Best of All, 205; Dark Red Erfurt, 205; Earliest of All, 205; Express, 205; First Crop, 205; Improved Nonpareil, 205; Incomparable, 205; Les Etampes, 205; Little Gem, 205; Market Garden, 205; Miniature, Red, 205; Myatt's Early Evesham, 205; Paris Market, 205; Small Nonpareil, 205; Sutton's Earliest, 205; Wheeler's Imperial, 205; French Bean Seedling Dwarf, 117; Grape Prince of Wales, 250; Oranges: Rennick Navel, 255; Washington Navel, 255; Parsley Massey's Dwarf Curled, 117; Pear Danias Hovey, 281; Potatoes: British Champion, 255, 268; Courtney Seedling, 117; Devanha Seedling, 255, 268; Midlothian Early, 117; Tomato Lye's Early Profitee, 205
 CERTIFICATED PLANTS:—Acanthos montanus, 452; Acinetum deusa, 254; Angraecum angustatum, 76; Asters: Climax, 295; Maidenhead, 295; Astilbe Arendsis Ceres, 75; A. Arendsis Pink Pearl, 75; Begonias: Chbran's Pink, 347; Duchess of Cornwall, 35; Frilled Queen, 35; Kewensis, 75; Brasso-Cattleya Clittonia, 418; B.-C.

- Mme. Chas. Maron, Sanders' variety, 191; B.-C. Mmie. Ilya superba, 316; B.-C. Queen Alexandra, 316; Bulbophyllum Careyianum, 381; B. cupressum, 348; B. lilacinum, 348; Calanthe Angela, 453; C. Cecilia, 191; C. Norman, 453; Carnations: cardinal, 75; Countess of Westonbirt, 116; Hercules, 75; Maud Allan, 98; Rose Dore, 420; Splendour, 75; Winona, 253; Catasetum Clavianum, 150; C. Inschootianum, 191; C. labiatum, 150; C. maculatum, 254; C. Russellianum, 191; Cattleya Maronii aurea, 221; C. Rhoda, 191; C. Clarkæ intensa, 548; C. Fabria Cooksonæ, 348; C. Harrisoniana alba, Stanley's variety, 221; C. Rutland, 254; C. Venus, 254; Chrysanthemum: Aurora Boreale, 401; Ball of Gold, 417; Caledonia, 381; Exquisite, 319; Fée Parisienne, 271; Felton's Favourite, 315; Hetty Wells, 347; Hilda Lawrence, 315, 319; H. W. Thorp, 347, 319; J. Locke, 319; J. W. Molyneux, 333; Kathleen Lambick, 271; Hon. Mrs. Lopes, 333, 347; Lady Crisp, 319; Lady Letchworth, 319; Master David, 315, 319; Master James, 271; Merstham Jewel, 381; Mrs. J. Kempsey, 271; Mrs. R. H. E. Marsham, 315, 319; Mr. W. Buckingham, 333; Mrs. W. Fagden, 333; Mrs. W. Faraker, 333; Mrs. Cora Storr, 333; October Gold, 271; Nellie Riding, 271; Province, 271; Purity, 347; R. F. Felton, 333, 347; Reginald, 333; Kathleen May, 401; Robert Thorp, 333; Rose Pocket, 319; Shanklin, 271; Sir Frank Crisp, 315, 319; Sylvia Slade, 333, 347; W. J. Davis, 319; W. White, 319, 333; Cirsium: Costatum Andersonii, 254; Cologny fuliginosa, 381; Coriaria japonica, 70; Cymbidium Dayanum, 285; C. lancifolium, 191; Cynorchis purpurascens, 254; Cypripedium: Antinous, 453; Arethusa, 381; Armstrongii, 418; Bianca superbum, 254; Charlesworthii Birmliovianum, 285; Dante magnificum, 348; Dreadnought, 381; Elator, 453; Lord Ossulton, Sanders' variety, 285; Rosettii, 150; Sanctæus Etionense, 381; Trolus Lord Nelson, 418; Dahlias: Adela, 206, 220; Ameha, 223; Betty, 220; Brigadier, 220; Debutant, 206; Echo, 220; Elsie Turner, 233; E. Vano, 233; Evening Star, 223; Fairy Queen, 223; Flora, 220; Glory of Wilts, 223; Rev. F. W. Jamieson, 206; Jasper, 206; Lady Bountiful, 254; Lufra, 223; Minima, 206; Monarch, 220, 254; Mrs. Alfred Dyer, 206; Mrs. W. Merry, 206; Nellie Riding, 220, 247; Nora Reynolds, 254; Satisfaction, 220, 254; Sarracena, 254; Snowdon, 220; Tasmania, 223; Teutonic, 220; Tom Jones, 190, 206; Una, 206; Wellington, 254; Winona, 223; Delphinium Progression, 35; D. Stataure Rude, 35; Dendrobium elongatum, 453; Dendrobium Colognyense, maximum, 316; D. C. striatum, 418; Dracæna: Beauvau variegata, 285; Epidendrum costatum, 76; E. Lambeauianum, 150; E. punctiferum, 453; Eria longispicata, 150; Geodorum purpureum, 76; Gladiolus Marathon, 190; G. primulinus hybrids, 190; G. White Cloud, 190; Habenaria geniculata, 254; Ilex: Krivi, 190; Knapik: "R. W. Hon. Ker," 190; Latio - Cattleya: Civea magnifica, 36; L.-C. Cornelia, Westobirt variety, 285; L.-C. Elva var. St. Vincent, 191; L.-C. Golden Oricle, Goodson's variety, 234; L.-C. Lustré gigantea, 316; L.-C. Ortrude superba, 116; L.-C. St. Gothard, 285; Liatrostachys Kindtiana, 150; L. Whyte, 116; Masevalina Ortigiesiana, 316; Maxillaria: phoeniceo-thera, 348; Megacalium columbinum, 285; Nelumbium speciosum var. Osiris, 75; Nepenthes Dr. John MacFarlane, 233; Nepenthes rufescens amabile, 347; N. rufescens Mayi var. ornata, 347; Nerine Countess of Altonmont, 285; Odontodia Charlesworthii, Goodson's variety, 254; Odontodia Thwaitesii, 70; Odontoglossum: Eleanor, Westobirt variety, 36; O. Grogonia, 281; O. illustre King of England, 36; O. Magali Sander, 453; O. Pescatorei Sander, 285; O. Wiganianum superbum, 150; O. Zenobia, 150; Oncidium bicallosum Sanders' variety, 453; O. incurvum, 254; O. micro-pogon, 281; O. pensetatum japonicum, 233; Phlox: Freifraglinc Von Lassberg, 190; P. Violet, 190; Pink, Princess Christian, 149; Polystachya flexuosa, 150; P. Laurentii, 348; Polystichum aculeatum gracillimum Druerni, 381; Populus lasiocarpa, 220; Primiula malacoides, 381; Pteris aquilina Nicholsonii, 190; Poses Alex. Hill Gray, 237; C. E. Wauke, 35, 94; Dr. O'Donnell Brown, 237; Florence Edith Coulthwaite, 35; His Majesty, 227; Lady Alice Stanley, 237; Lady Godiva, 75; Mita Weldon, 40; Mully Sharman Crawford, 35; Mrs. Alfred Tate, 285; Mrs. David Jardine, 35; Mrs. Edward J. Holland, 285; Mrs. J. Campbell Hall, 40; Mrs. Littleton Dewhurst, 295; Mrs. Wakefield Christie Miller, 285; Paula, 116; Simplicity, 96; Willie Dorothy Perkins, 96; Saccolabium dasy-pogon, 316; Sarcococca rusci-folia, 453; Selaginella emilia-na aurea, 253; Sinningia hybrida Dr. Maxwell T. Masters, 75; Sophro-Cattleya Doris, 348; S.-C. Warnhamensis var. J. M. Black, 116; S.-C. × Saxa, J. Westobirt variety, 254; Sophro-Labio-Lattiseya Danae superba, 191; S.-L.-C. Marathon, 150; S.-L.-C. Medea vinicolor, 150; Stanhopea tigrina superba, 76; Sweet Peas George Stark, 98; Miss Constance Oliver, 97; Mrs. H. Bell, 98; Mrs. Ireland, 97; Paradise Ivory, 97; Thalictrum dipterocarum, 149; Trichoplia nobilis alba, 150; Tritoma: Hereford, 190; T. Novæ, 190; Tunica Saxifraga fl. pl., 35; Vanda amara var. Sanderæ; V. cœrulea Charlesworthii, 316; V. cœrulea "R. Chollet," 381; Viola cornuta purpurea, 253; V. Ernest Needham, 35
- Cheddar Pink, the, 214
Cherries, maggots in, 53
Cherry, the Cornelian, 53
Chertsey gardeners and the Gardeners' Royal Benevolent Institution, 363
- Chicago flower show, the, 325, 408

China, plant collecting in, 394; viticulture in, 12
Chinese vegetable tallow, 112
Choisya ternata in the Midlands, 346, 380; hardness of, 416
Chrysanthemums, damping in, 416; Felton's Favourite, 330; Japanese varieties for decoration, 40; tables decorated with, at the flower shows, 401, 451; in France, 313, 395, 396; in the London parks, 358, 436
- Chrysanthemum shows and the R.H. Hall, 268
Cirrhopetalum Macraei flowering at Gatton Park, 179
Clarke, W. H., retirement from Aston Rowant gardens, 259
Clark, Mr. G. D., honour for, 91
Clematis indivisa as a plant for forcing, 346
Climanthus puniceus albus, 23
Climbing plants, evergreen, for a conservatory wall, 336; at Craig-mish Castle, Argyll, 346
Climbing Roses, early-blooming, 64
Cloth made from Pine leaves, 280, 360
Club, the R.H.S. employees, 51
Coal, anthracite, for greenhouses, 335
Cold chambers, how to construct, 321, 336, 374; for fruit, 201; for Oncoclytus Irises, 32, 115
Colonial exhibition, 339
Colonial notes, 46, 63, 425
Colour chart, the, 187; and the mirex, 219; a new, 218
Colour mutations in Leptospermum scoparium, 54
Compositæ, shrubby and soft-wooded species of, 23
Conference on the spraying of fruit trees, 185, 300, 316
Congress of Alpine gardeners, 12
Conservatory, plants for an unheated, 422; wall climbers for a, 336
Co-operative flower show, 146
Copal or anime, source of, 11
Coprinus mucosus and other garden fungi, 201
Coquilla-nut Palm, the, 396
Coriaria japonica, 73
Corrus Mas, 53
Cotton growing in Barbados, 46
Cours Ja Reine greenhouses to be demolished, 92
Covent Garden Market, tropical fruits in, 443
Crane, Howard H. (*The Book of the Pansy, Viola, and Violet*), 178
Crataegus flowering in November, 380; in December, 438
Crataegus, Missouri species of, 111
Cricket at East Burnham Park, 12; at Wisley, 147
Crossandra undulfolia, 106; in a Java nursery, 291
Croydon, small holdings at, 299
Cryptococcus laqi (felted Beech coccus), 257
Cucumber Sutton's Every Day, 323
Cucurbita ovifera, 25
Cultural memoranda, 25, 81, 104, 212, 227, 392
Currant, black and red, attacked by American Gooseberry-mildew, 203
Custard, Apple, the, 443
Cyaniding a plant stove, 207; vineries in winter, 336; wasps' nests, 51
Cyperaceæ, new genera and species of, 233
Cypress wood, durability of, 250
Cypripedium: Actæus Bianca, 261; C. Dreadnought, 380; C. Sanctæus Etionensis, 416
Cytisus × Beanni, 339, 449
Cytisus × kewensis, 323
- FACTORY ACT and commissions to florists, 217
Fairlaw, Putney, Orchids at, 305
Falconer, William (*Managers and How to Grow Them*), 229
Fan-trained fruit trees, 233, 269, 282
Farmer, Prof. J. Bretland (*The Book of Nature Study*), 391
Farmers and science, 345
Ferrari, Giovanni Battista, 218
Farrer, Reginald (*Alpines and Bog Plants*), 409
Fatsia Sieboldii as a market plant, 144
Federation of horticultural societies in Holland, 31
Femel, Italian, 133
Fern, Mr. Merritt L. (*Gray's Manual of Botany*), 412
Fern hunting in Devonshire, 463
Fern society, a proposal, 314

- Fernery, the, 163
 Fibre from Bananas, 413; from
 Pine leaves, 280, 366
 Finsbury Park, Chrysanthemums
 in, 308
 Fisher, W. (*Forest Utilisation*), 392
 Floral mechanism, types of, 70
 Floricultural history, 293
 Florists and the Factory Act, 217
 Florists' flowers, 122, 162, 194, 212,
 323
 Flour and paraffin emulsion, 449
 Flower garden, the management of
 the, 9, 28, 49, 68, 83, 108, 127,
 141, 164, 181, 198, 215, 230, 247,
 263, 279, 280, 310, 327, 342, 360,
 376, 393, 411, 431, 447
 Flowers, female, of Begonia Gloire
 de Lorraine, 204
 Flowers, forcing, by hot water, 12;
 in season, 11, 167, 330, 363; in
 the Transvaal, 63; unseasonable,
 363, 367; visited by butterflies,
 304
 Flowers of Spenser, 6, 15, 26, 32,
 43, 54, 65, 73, 94, 103, 124, 138,
 172, 204, 251, 282
 Flower the flowers, at the Paris
 Salon, 32, 35; seeds difficult of ger-
 mination, 170, 219; show at Hol-
 land House, 33; show, a village,
 193
 Fobage, fine, plant at exhibitions,
 265

SUMMER PRUNING.

THE time for summer pruning hardy fruit trees is once more at hand. It may be confessed that, like many other gardening practices, it is liable to misapplication and abuse. Why do we summer-prune fruit trees, of which for brevity's sake the Apple may be chosen as an example? Some will reply that it is in order to induce the formation of fruit buds for another year. Others, to relieve the tree of a redundancy of shoots, while not a few perhaps have only custom to fall back upon for a reason. It is not wise to laugh at a thing because it has nothing but custom to recommend it, and it is not always safe to break away from that which long usage has sanctioned as almost imperative, but at the same time it is not a stable footing to rest upon. Therefore custom may be set aside as being not altogether satisfactory. The other reasons are perfectly sound. I do not recall any season in which there has been such a profusion of clean, healthy foliage as the present, nor one in which the work of dis-budding has needed more time. It should be remembered that summer pruning, properly understood, is simply a corollary to dis-budding, and both are indicative of a system of repression that is artificial, but none the

less beneficial. Our cordons are artificial in intent and in fact; the very fruit they bear is to some extent imbued with the character of artificiality, for in comparison with that produced by a standard in a large measure left to itself, the size and quality of the two differ essentially.

In summer pruning the first question one has to solve is whether any more buds are required than the tree already is able to mature, or whether there are already too many. It is quite possible that the latter case may be the condition of the tree; and if so, it is obvious that much of the pruning will resolve itself into a removal of the weaker and worst placed spur-buds, including not improbably here and there a whole spur. Many persons approach summer pruning without considering the possibility of a tree carrying more spurs and potential fruit buds than is good for it. But, no doubt, such a condition is not only possible but highly probable, the high state of perfection to which indoor fruit-culture has been carried proving that it is, to say the least, unwise to overload a tree with more buds and foliage than it can usefully employ.

Shoots that have been allowed to extend, and are considered necessary to preserve and to shorten, are sometimes allowed to harden somewhat before being pruned, the idea being that secondary growths will not obtrude themselves at that stage. The rationale of "thumb" pruning has been rather lost sight of by its opponents as well as by those who, unwittingly or not, practise this method of shortening. They fear that the growth of a shoot being abruptly terminated, the buds which it was hoped would be preserved and matured will, on the contrary, be presently forced prematurely into growth. Yet observation shows that shoots may be shortened while yet absolutely immature and that only one or two of the uppermost buds push into growth. It is according to how these are treated that the utility of thumb pruning, as opposed to knife pruning, which is equivalent to late pruning, rests. It is usual to pinch the tips of these repeatedly, and the little shoots which succeed them, in the vain expectation that they exert some obscure influence on the roots. Yet the best method to pursue is to rub off all the secondary growths as they are produced, leaving only the primary leaves, the value of which can hardly be over-estimated, because we know when these have been crippled or destroyed by any means the secondary foliage on which the tree has then to depend, while serving to keep it in existence, is nevertheless incapable of assisting a crop of fruit to develop to anything near perfection, or of enabling the tree to provide for the succeeding crop. On the other hand, with a limited quantity of primary foliage the tree is able to mature the current year's crop and to provide for that of the succeeding year.

To draw these few threads together, I think it must be clear that the removal of shoots and foliage obviously beyond the necessities of the tree is beneficial. That the sooner a tree is relieved of what is superfluous, must, in the nature of things, tend to induce vigour and fertility, and that, once relieved, the tree should as far as possible be kept in the same condition during its state of active growth, free from "spray," which is capable only of affecting it prejudicially. B.

DISEASE OF SEAKALE.

IN the autumn of 1906 serious damage to various kitchen garden crops was noticed in the vegetable department at Wye College, Kent. This damage proved to be due to the attacks of the fungus *Rhizoctonia violacea*, a root or stem-parasite capable of attacking a very wide range of host-plants. This fungus had not been noticed before in the gardens, but on raising the root crops it was found that during the season it had attacked several crops. The disease had done considerable damage to the Salsify, reducing the crop by fully one half; the fungus had also attacked Parsnips and Carrots, and, to a very serious extent, the Seakale, the crowns of which (required for the next year's forcing) were rendered useless to the extent of nearly half the crop. Many of the diseased crowns had rotted away.

The fungus *Rhizoctonia* is seen as a felted mass of violet spawn, or mycelium, adhering closely to the surface of the root, upon forming conspicuous violet or purplish patches. The threads (hyphæ) of the spawn are very characteristic in appearance when seen under the microscope; they are violet or purplish in colour, rather thick, and branched rather frequently at right angles. Scattered about over the spawn, or sometimes densely clustered, are usually to be found numerous small, firm, violet bodies, appearing to the naked eye as minute, round specks not unlike the heads of very small pins. These bodies are called sclerotia, and are, in fact, little globular masses of the spawn in a resting condition. They are composed throughout of densely interwoven hyphæ compacted into practically a solid mass of tissue. A microscopic section through one of these sclerotia shows at the base a mass of hyphæ passing right into the tissue of the host-plant, and it is thus that the host is attacked, and the necessary nourishment obtained by the fungus. Decay of the tissues of the host-plant ultimately sets in over the affected areas, and in severe cases of attack the whole, or, at any rate, a large area of the root or stock rots away, either before or after the plants are stored. The sclerotia may be looked upon as carrying out the function of winter spores, since they are capable of remaining dormant for a long period, being very resistant to cold, drought, or other unfavourable conditions. Then, when suitable conditions again obtain, the sclerotia grow out into the ordinary vegetative spawn of the fungus, which extends through the soil, attacking various plants as it reaches them.

So serious were the effects of the disease on the Seakale that it was decided to try various remedial measures during the season of 1907. The recurrence of the disease, if no steps were taken, was almost a certainty, since in the first place some of the cuttings used (which were all taken from the crop previously grown) had in all probability borne numerous patches of the fungus, since it occurred so plentifully on most of the roots; and secondly, the position of the Seakale bed being required to be the same, there was a strong probability that the soil was already infected with sclerotia, and possibly with growing spawn. It was, therefore, decided to treat portions of the bed with various soil fungicides. Just before the planting of the cuttings, in March, 1907, the bed was divided up into 11 plots. The size of each plot was 19 feet by 9 feet, with the exception of Plot 2, which measured 9 feet 6 inches by 9 feet, and Plot 3, which measured 28 feet 6 inches by 9 feet. The Seakale was planted in rows, the cuttings being about 18 inches apart in the row. The plots received the following treatment:

Plot 1.—Copper sulphate solution, 1 lb to 1 gallon water; 40 gallons applied.

Plot 2.—Saturated solution of iron sulphate

with 1 per cent. sulphuric acid; 20 gallons applied.

Plot 3.—Control plot; no treatment.

Plot 4.—Mercuric chloride (corrosive sublimate), 1 ounce to 8 gallons water; 40 gallons applied.

Plot 5.—Phenol (carbolic acid), 1 ounce to 1 gallon water; 40 gallons applied.

Plot 6.—Formalin (commercial), 2 ounces to 1 gallon water; 20 gallons applied.

Plot 7.—Formalin (commercial), 1 ounce to 1 gallon water; 20 gallons applied.

Plot 8.—Petroleum 3 parts, water 10 parts; 40 gallons applied.

Plot 9.—Control plot; no treatment.

Plot 10.—Sulphur ("flowers of sulphur") at the rate of 600 lbs. to the acre, worked into the surface soil.

Plot 11.—Control plot.

Plot 12.—Quicklime at rate of 4 tons to the acre, worked into the surface soil.

The phenol, corrosive sublimate, copper sulphate, and iron sulphate were dissolved in water; in the last case the water was hot, and contained the sulphuric acid. The formalin and petroleum were mixed with water, though in the latter a complete mixing was impossible. All the above fluids were applied to the respective plots by a watering-can with a fine rose. The sulphur and lime were applied dry, and mixed into the surface soil.

A few days only after the treating of the soil the Seakale cuttings were planted.

During the summer little difference was noticeable throughout the bed, beyond the fact

that, owing to the very bad tilth brought about by the application of the petroleum, the growth not only of the crop, but also of weeds, was

that the application of the petroleum had affected adversely the growth of the plants. Their growth was noticeably checked in the spring, and the plants subsequently did not make so good a leaf growth as on the other plots, with the result that, on being dug, the crowns proved to be the poorest, and the roots the thinnest, in the whole of the plots.

Plot 10 (sulphur).—While the growth of the plants was good, the disease was prevalent on the crown and roots. There was as much disease here, in fact, as in Plot 11 (control), and it is doubtful if the treatment did any real good at all.

Plot 11 (control).—Disease prevalent on the crown and roots.

Plot 12 (lime).—For some reason the plants were rather poor, the roots being decidedly weaker than in the other plots. There was, however, an almost complete absence of disease on them. The effect of treating infected soils with various quantities of lime certainly requires to be tested further.

Although the positive results obtained in the above series of experiments on treating Rhizoctonia-infected soil with fungicides must be confirmed by further tests before absolute reliance can be placed upon them, the result obtained by the use of carbolic acid was so striking that I have thought it well to mention the fact now instead of waiting for the results of further experiments with soil fungicides in the hope that gardeners troubled with this disease on Seakale, or on other plants, will try the use of this simple and inexpensive remedy. Carbolic acid of 90 per cent. purity can be obtained at 8d. a pound, and a pound is sufficient to treat about 4 square feet. The apparently stimulated growth of Seakale in soil treated with carbolic acid is a point of interest.

If Seakale is attacked by the Rhizoctonia disease, there is every reason for the gardener to endeavour to get rid of the pest, not only on account of the damage it will inflict on this

FIG. 2.—PORTION OF TWO ROOTS OF THE PLANT SHOWN IN FIG. 1, MAGNIFIED, SHOWING THE GROUPS OF SCLEROTIA AMONG THE PURPLISH-VIOLET MYCELIUM.

greatly checked; in fact, areas here and there in this plot remained bare all through the summer.

On lifting the crop in the autumn a considerable difference was noticeable in the health of the crop in the various plots. Although the disease was not so virulent as it had been in 1906, it was sufficiently so in the control plots, and in some of the other plots also, to be the cause of considerable harm. The attack was not severe enough to cause the crowns to rot (as happened in 1906), yet it was present on some plots to an extent sufficient to make the crowns much weaker than they would otherwise have been. Also, in several of the plots the disease occurred plentifully on the roots; here the danger was that "cuttings" from such affected plants would introduce the disease into the soil of other portions of the garden. This constitutes a real danger, since, as mentioned below, the Rhizoctonia disease is able to attack a large number of cultivated plants. The treated plots gave the following results:—

Plot 1 (copper sulphate), Plot 2 (iron sulphate), Plot 3 (control).—Disease prevalent on crown and roots, and although in the case of Plot 1 there was perhaps a slight improvement, it did not appear that the use of either copper sulphate or iron sulphate applied in this way was of any practical use against the disease.

Plot 4 (corrosive sublimate).—Disease prevalent on the crown, but did not occur, as a rule, on the roots. While the treatment was productive, apparently, of some good, it was clear that the use of corrosive sublimate did not clear the soil of the disease.

Plot 5 (carbolic acid).—In this plot not only were all the plants practically free from the disease, but the crop was heavier and better in every way than on the other plots, the crowns being much larger and the roots stouter, and quite free from the disease. It certainly appeared as though the application of the carbolic acid had stimulated the growth of the plants.

Plot 6 (formalin), Plot 7 (formalin), Plot 8 (petroleum), Plot 9 (control).—No satisfactory results. There was as much, if not slightly more, disease in the formalin plots as in the control plot, and the plants were poor. In the petroleum plot the disease was as prevalent and as severe as anywhere, also, it appeared

FIG. 3.—A "CUTTING" TAKEN FROM A DISEASED PLANT.

The purplish-violet mycelium of Rhizoctonia appears as dark patches on the roots (as at x).

crop, but because the fungus Rhizoctonia is able to attack numerous other cultivated plants. For instance, Asparagus beds may replace the Seakale bed, when the former plants will be liable to be attacked by the sclerotia remaining in the soil. In Belgium serious injury to Asparagus beds has been reported from this cause.

FIG. 1.—PLANT OF SEAKALE AFFECTED WITH RHIZOCTONIA VIOLACEA.

Purplish-violet patches of mycelium occur on the crown and on the roots. Densely clustered groups of sclerotia have been formed here and there (as at x).

Among other plants liable to be attacked by *Rhizoctonia* are the Carrot, Parsnip, Turnip, Salsify, Beetroot, Fennel, Lucerne, Clover, Saffron, and a number of wild plants. In the United States it is reported as being a common cause of the "damping-off" of seedling plants (including Lettuce, Cabbage, Radish, Bean, cucumber). It has been known to attack Rhubarb, affecting the base of the petioles of the leaf; a stem rot of Carnations has also been attributed to the same cause.

Two cases occurred recently in the vegetable department at Wye College. In the first case the roots of several plants of Parsley (which had been planted along one side of the affected Seakale bed) became attacked, and were gradually more or less destroyed. It does not appear that Parsley has hitherto been recorded as a host-plant of *Rhizoctonia*. In the second case seedling plants of Lettuce were attacked and destroyed in much the same manner as when attacked by the true "damping-off" fungus.

Finally, it must be mentioned that a species of *Rhizoctonia* often attacks the Potato, forming small hard, blackish or brownish sclerotia on the surface of the tuber. The sclerotia are very firmly adherent to the skin of the tuber, so that scrubbing with a scrubbing brush often fails to remove them. In the autumn of 1907 this disease was noticed for the first time on the Potatoes in the vegetable department at the College. On microscopical examination it does not appear that the hyphæ of the mycelium break through the skin of the tuber, but, together with the sclerotia which are formed later, remain entirely superficial. Thus no harm, apparently, is done to the tubers, except that the appearance of the tubers when the attack is severe is ruined for show purposes. There is also the danger that by the use of *Rhizoctonia*-infected "seed" Potatoes a gardener may introduce the fungus into healthy soil, where it may extend and attack various crops. In the United States, Prof. Clinton, in 1905, described and figured *Corticium vagum* var. *Solani* as the fertile stage of *Rhizoctonia*. Further, a "rosette" disease of the Potato "haulm" (which causes an early dying of the "haulm" before the formation of many tubers, and also an excessive branching and "rosette" or clustered arrangement of the branches) has, in the United States, been traced to *Rhizoctonia*.

Experiments planned to ascertain whether the *Rhizoctonia* on Seakale is able to attack Potatoes, and also whether Potato tubers affected with *Rhizoctonia* can be "steeped" in a chemical sufficiently strong to kill the sclerotia, are already in hand. *E. S. Salmon, F.L.S., Mycologist to the South-Eastern Agricultural College, Wye, Kent*

NOTICES OF BOOKS.

* VEGETABLES FOR HOME AND EXHIBITION.

THE author of this work upon that useful branch of gardening—the cultivation of vegetables—is one of the most successful cultivators of the plants about which he here descants, and he frequently secures the highest prizes at exhibitions for vegetables. As a book to be read with interest by every gardener who is responsible for the supply of culinary vegetables to a country house, it is extremely useful, and for the exhibitor indispensable.

In order to make the book easy of reference, the various vegetables are arranged in alphabetical order. Asparagus cultivation, as may be imagined from its foremost place as a vegetable, forms the subject of a long chapter. The author combats the erroneous idea among cultivators that to grow good Asparagus, the necessary cost in materials, labour, and time is enormous. He describes the methods adopted

at Aldenham, which are by no means onerous or costly; and they are those that may be readily undertaken in any fairly good soils, especially in friable and sandy loams. In heavy clays there must be large additions of lightening materials incorporated with the staple—that is all. No other choice vegetables repays the outlay to a degree equal to this one, the only drawback being the three years of waiting until the first cutting takes place. The present writer knows some dozen beds in a north country garden that had borne good crops without a break for 50 years; but the best produce can only be obtained from moderately young plantations. Many an Asparagus bed has been ruined by too early and excessive cutting of the shoots. No shoots should be taken till the second year after planting, and then only a very few from the strongest stools. Inter-cropping, as is sometimes done, is to be deprecated as a general practice. Where every bit of garden soil must be cropped, the alleys between the beds may be cropped with Lettuces or Cauliflowers. Clay's fertiliser at the rate of 1 oz. per square yard is recommended for occasional employment. Seed sowing and forcing come in for appropriate remarks. In the same thorough manner French Beans and Runner Beans are treated upon, of which last several white-flowered varieties are promised, one being *Jubilee* and the other a seedling from *Scarlet Emperor*. There is a chapter on Beetroots, including the useful *Seakale* variety, whose midribs may be pulled off in early autumn, and cooked and served in the manner of Seakale. Borecoles or Kales, and the Russian *Labrador* varieties when true, are specially praised for their hardiness and abundant cropping. Similarly, Broccoli are comprehensively treated, and a number of fine varieties are indicated; but we note no mention is made of the *Early Penzance*, which comes into use in the early winter months, and is as delicious in flavour as a Cauliflower, with the curd of a pure white. Brussels Sprouts and Cabbages fill several pages of matter; of the former *Dwarf Gem* and *Cambridge Champion* are much appreciated; the *Flower of Spring*, for early cropping, and the old *Wimmgstadt* are specially mentioned, the latter as a summer cropper. In regard to Cauliflowers, the author states that with the many splendid varieties now in cultivation, it is an easy matter, where glass accommodation exists, to provide a regular supply of Cauliflowers from April to Christmas. He still adheres to the old practice of sowing seeds in August and September, wintering the plants in handlights and frames, in preference to sowing early maturing varieties in heat, nursing the plants in heat, and planting out as early as the weather will permit. The reason he gives for his preference is that although this method gives more trouble, the heads are finer and firmer, an opinion with which we quite agree. A hint is given to exhibitors of Cauliflowers to make many small sowings, so that they may have good produce at the various shows. No other vegetable occupies a more important place in collections of from six to twelve dishes. For spring sowings *Early Giant* is a most desirable variety. The chapters on Onions and Peas are of considerable length, as might be expected from the importance of these vegetables from a culinary point of view; and the book contains a mine of practical information in regard to their cultivation. The excellent advice is given about sowing Onion seed—to sow in the open twice as thickly as it is intended the plants should remain, and to apply artificial manure during showery weather to assist growth. We have found earth-closet manure that has been six times through the closer (Moules' patent) a most efficient aid. The section on growing Onions for show purposes is most appropriate. The author has for some years been interested in raising new and improving existing varieties of Peas, his aim being to produce types that possess a good con-

stitution, are free-bearing, have a handsome appearance with the Peas of fine quality. Edwin Beckett was his first good variety, receiving an Award of Merit at the Chiswick trials. He has had nothing to excel it as a second early for home use or exhibition. His next introduction was *Quite Content*, the largest podded Pea in cultivation. There are numerous hints on sowing worthy of notice by exhibitors and gardeners in general. Stopping and thinning are noted, and the information on exhibiting is useful. Mr. Beckett is a believer in deep trenching and heavy manuring.

Potatoes and their cultivation are fully treated upon from the garden point of view, and a very good list of varieties is appended. For exhibition purposes spaces of 2 to 3½ feet are recommended between the rows, and 2 feet from set to set.

A sowing and planting table, and a chapter on exhibiting vegetables, and one on insect and animal pests and their destruction, are found at the end of the volume; likewise a compendious index to matter and illustrations.

NOTES ON IRISES.

IRIS TECTORUM ALBA.

THIS Iris, which is one of the most delicate and beautiful of all, may easily be raised from seed, and the resulting plants are all white flowered. Plants raised from seeds ripened in 1906 are now in flower here, having stood the winter well, though entirely unprotected. The white variety differs, as far as my observations go, from the type in having a stem that is only one-headed, the spathe usually containing two buds, while *I. tectorum* always has a considerably taller stem, which branches to form several heads. I should be glad to know whether anyone has found that the white variety produces similar branching stems.

IRIS OLBIIENSIS × KOROLKOWII.

THIS is an interesting hybrid of a claret-red form of *obliensis*, often known as *Socrates*, crossed with a form of *I. Korolkowii*, the latter being the pollen parent, and it came into flower for the first time in May. The plant combines the characteristics of both parents in practically equal degrees. The foliage is that of *obliensis* except that the bases of the shoots have the reddish-brown colouration of most varieties of *Korolkowii*. The flower is of *obliensis* shape and colour, in so far as the groundwork is concerned, but both standards and falls are conspicuously overlaid with the black-brown veining of *Korolkowii*, and they run together on the falls to form a black signal patch. The dingy yellowish beard is also the product of the combination of the bright yellow of the female parent with the black of the male.

IRIS VAGA.

I HAVE this year noticed an extraordinary variation in colour in the beard of this Iris. In 1907 I had about twenty plants in flower, some having bright yellow beards, while in others the colour was a bright vivid blue. The difference in the general appearance of the flowers was quite noticeable by even the most casual observer. I carefully labelled each plant and, when I lifted them, I separated them according to the colour of the beards and replanted them in different beds. This year I had over thirty spikes of flower on these two beds, but in no case was there a bright yellow beard. Every flower was of the blue beard variety, though in some cases there were a few dull yellow hairs far back beneath the style branches.

Iris vaga and *I. Leichtlinii* are usually supposed to differ chiefly in the colour of the beard, but if this colour is liable to vary on from year to year, how can we tell whether a given flower is *I. vaga* or *I. Leichtlinii*? *H. R. P. D. v. Charlotterose, Godesalming.*

* By Edwin Beckett, V.M.H. London: Simpkin, Marshall, Hamilton, Kent & Co., Ltd. Price 5s.

THE ROSARY.

CULTURAL HINTS FOR JULY.

Rose plants generally are developing a healthy growth, and, assuming the foliage to be free from fungal and insect pests, it is nevertheless necessary to employ preventive measures in order to keep the leaves in this condition. This can be done by syringing the plants occasionally with solutions of soft soap, Quassia Extract, and tobacco water. The plants should be sprayed with these specifics during the evening, and be washed with clear water on the following morning.

Standard Briars will now be in the best condition for budding, provided all the superfluous growths were removed last month, and three of the best were retained near the top of the stock. The process of budding Roses has been so often explained that it is hardly necessary for me to do so just now, but I will emphasise the necessity of observing a few details. In the first place the bud should be inserted on well-

will be best done early in the morning, in the evening, or on dull days. If the weather is very hot and dry, loosen the surface soil and apply a good mulch and an abundance of water some time before budding and afterwards, or until the advent of rain.

The present is a suitable time to visit a Rose nursery to make a selection for autumn delivery, for the best varieties in all classes are now in flower.

The maiden buds can be examined, tied and staked for the last time, and any long shoots now taking the lead over others should be stopped. When the growths proceeding from these buds have flowered they may be pruned back a few "eyes" to cause fresh shoots to break and flower later. Old plants, after flowering, may also be pruned in a like manner. The hybrid Tea, China, and Bourbon Roses respond well to this treatment.

The pegged-down Roses referred to in previous notes will now be yielding a wealth of bloom and flower buds, if previous instructions have been carried out.

of the leaves. This comparative drought may be continued until September.

Plants with their roots in borders under glass require similar treatment, and all the ventilators should be left open day and night. An insecticide should be applied over the plants by means of the garden engine, but if the top lights could be removed altogether this would probably be the most effective method of keeping the plants clean.

Roses which were raised from grafts or cuttings and being still in pots 3 inches in diameter should be given a final shift into 5-inch pots, and be plunged in beds out of doors, where they will develop their summer and autumn growth. A cool and comparatively rich rooting medium with foliage exposed to the night dews will favour sturdy and vigorous growth by the end of the season. Stopping of the shoots should not be continued later than July.

Exhibitors should refer to the hints given in the article that appeared in the first issue for June, as many of the directions then given will now have to be put into operation. Liberal mulchings from spent hot-beds, if applied to the borders at this season, and copious waterings are subsequently given, will have very good effects: if the mulchings are considered to be unsightly, the material may be covered with a little fine soil. Remove faded and dead blossoms from all rose plants as soon as they are seen, and stir the surface soil with the hoe frequently. Cuttings which were inserted during autumn or winter may suffer from lack of moisture at the roots unless attention is paid to them. J. D. G.

FIG. 4.—ODONTOGLOSSUM AMABILE FOWLERIANUM.

matured shoots only, and the scions must be well matured and obtained from the bottom "eyes" of a shoot. In the second place, the operation should only be carried out when the bark will open freely from the wood without any bruising. Be careful when removing the wood from the bark of the scion to leave the "eye" (a prominent one) intact. Insert the bud in the axil of the shoot and as near to the main stem as is possible. The raffia to be used for tying and closing in the bud should be first well soaked in water, and the end of the shoot which furnishes the scion should be kept in water also as the process of budding proceeds.

In the case of dwarf seedling Briars or Briars raised from cuttings, the surface soil should be removed a few inches deep, so that the bud may be inserted just above the root. This will, in a great measure, prevent suckers springing from the base. If only a limited number of stocks are to be budded, the work

All growing plants should be given plenty of liquid manures when the flower buds begin to show, but the soil should be moist at the time of its application, for then liquid manures are much more effective. These stimulants may be applied twice weekly, and one application of artificial manure may also be given each week. The manure water, if strong, must be diluted to one-half or one-third of its strength with clear water, for it is better to give it in a weak condition than to run the risk of causing injury to the roots. I have found soot to be a remarkably good fertiliser for Roses when applied with the manure water.

Do not permit overcrowding of weak and useless growths in established bushes, but thin them out as may be deemed necessary.

All forced Roses in pots require a good rest, and they should be kept as dry at their roots as is possible without causing absolute flagging

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM AMABILE FOWLERIANUM (see fig. 4).

(O. CRISPUM PUNICIAUM VIOLACEUM × O. CRISPO-HARRIVANUM.)

This is a superb hybrid with flowers 4 inches across, broad and well displayed in all its parts, and most exquisitely coloured, now flowering for the first time in the collection of J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis). The inner two-thirds of the sepals and petals are of a bright purplish-mauve colour, a few white spots appearing on the petals, and two or three irregular white lines on the sepals. The outer third of the sepals and petals is pale violet colour, the margins of all the segments being silver white. The broad labellum is white in front, red around the yellow crest, and beautifully marked with rose colour on the sides. It is a marked instance of the advantages to be gained by using fine varieties for hybridising.

DENDROBIUM AMENUM.

This fragrant species is flowering with Dr. Gordon Paterson, South Lodge, Ascot, who kindly sends flowers of it. It is a slender species, widely distributed in the Himalayas at a high altitude, and although tolerably plentiful in gardens many years ago, it is now seldom seen. Its slender stems bear fascicles of two or three flowers, all the segments of which are nearly equal, and generally white, with magenta tips, the colouring at the apex of the lip being darkest. The margin of the lip is undulate, the disc greenish-yellow, with a few narrow purple lines on each side. Frequently the flowers are tinged with rose, and an odour resembling that of Violets is very pronounced.

CATTLEYA WARSCEWICZII "FRAU MELANIE BEYRDORF."

Of the many handsome Cattleyas at present in flower in the collection of J. Gurney Fowler, Esq., this is the most beautiful, its large blooms being much finer than when it obtained

its First-Class Certificate at the Holland House Show in 1904. The sepals and petals are pure white, the tube of the lip white, with a pale sulphur-yellow disc, and some short purple lines on the upper margin. The front of the labellum is finely developed, and in colour is violet-tinted crimson with a clear white undulated margin. It is a very large specimen, furnished with many flower-bracts.

ODONTIODA CHARLESWORTHII.

This beautiful hybrid, obtained by Messrs. Charlesworth and Co. between *Odontoglossum Harryanum* and *Cochlioda Noezliana*, and which was awarded a First-Class Certificate at the recent Temple Show and illustrated in the *Gardeners' Chronicle*, May 30, p. 353, is still in flower in the collection of J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), who purchased the plant, and it is interesting to note the changes in its colour since it first expanded its blooms. When first open the flowers were ruby-crimson, with a slight violet shade which passed off in a few days, after which the colour became brighter and less deep in tint, until at present they are of a blood-red colour with an orange tint around the yellow crest. There is a very fine collection of these richly-coloured *Odontiodas* at Glebelands, but this is certainly the finest and most promising for hybridising purposes, a use to which it has already been put.

TEMPLE NEWSAM, NEAR LEEDS.

THE name of Temple Newsam seems to have a fruity sound when mentioned in connection with horticulture, and fully fifty years ago, when the estate was owned by the Meynell Ingram family, Grapes, Peaches, and especially Pineapples were leading products of the gardens. The writer remembers hearing of Providence Pines grown at Temple Newsam weighing up to 12 lbs. each. At that time the gardener was a Mr. Taylor. The estate is now occupied by the Hon. E. L. Wood, a nephew of the late Hon. Mrs. Meynell Ingram. What may be termed the general produce garden is situated some distance from the mansion, and here are erected the glass structures. The soil is stiff and cool, such as is generally found in the carboniferous formation. The uncropped ground in the large kitchen garden is ridged fully 5 feet from centre to centre: Mr. Dawes, the gardener, informed me he has practised ridging for many years, and found it to be the only method of dealing satisfactorily with the stiff soil in order to obtain good summer, autumn, and winter crops of vegetables. Plenty of manure and well-rotted leaves are worked in when ridging, hence in fine weather in spring and early summer it is possible to procure a good tilth for the sowing or planting of the various crops, and these are as forward and as promising as if the natural conditions were quite favourable. On entering the glasshouses which are still largely used for fruit growing, evidences of high culture are at once apparent. Mr. Dawes was for some years foreman to the late Mr. Colman, of Eastnor Castle, when he was at the height of his fame as a fruit-grower and exhibitor. The first range I visited consisted of vineries. The building measured 100 feet in length, and was 28 feet in width, divided into two compartments. They were erected a few years ago by Messrs. Foster & Pearson, and replaced some old houses of about half their width. The old vines were left, and these now occupy the upper half of the roof surface, where they produce fine crops of fruit. In course of time some, if not all, of these vines will have to be removed to make room for young vines that have been planted in new borders near the front of the vinery. These young vines are planted 4 feet apart, and as there is no need to hurry them to furnish the roof, they are forming stout bases and promise in due

time to develop exhibition bunches of Grapes. One division is mainly filled with vines of the Muscat family, and the rods are already carrying fine, well-set bunches. The other is a mixed vinery containing Black Hamburg, Gros Colmar, Prince of Wales, very promising Barbarossa, Gros Maroc, and others. The variety Diamond Jubilee is to be discarded. At present the roots of these young vines are confined to inside borders.

Adjoining this vinery is a long range planted with Peaches and Nectarines in fine health and cropping heavily. The front is higher than usual, the trellis being carried up some 18 inches from the glass for two-thirds of the roof space, and then curved downwards, thus affording light to the trees on the back wall. At present a row of pot-grown trees of Apples, Pears, and Plums occupy the centre, a temporary stage being utilised to bring them nearer to the glass. In nearly every case the trees were furnished with a good set of fruit, the Apple trees in particular being well cropped. Gardeners who have had experience in cold northern districts, and who have to supply dessert fruits in the late autumn and early winter months, will know the value of pot-grown fruit trees. I am hoping later on to give you the names of those found to do the best at Temple Newsam. Alexander and Amsden June Peaches were mostly gathered. That splendid old Peach Abec does exceedingly well, although not ripe. There was promise of fine crops in both the early Muscat and Hamburg vineries, Madresfield Court being very promising in the former house. Like most exhibitors of fruits, Mr. Dawes knows the value of having a number of trees in a limited roof space, both with a view to getting them ripe at the right time and enabling them to have special feeding with stimulants. Wherever there was a fit sunit space it was occupied with either a Peach, Nectarine or Fig tree, mostly as half standards in tubs or in boxes. It was almost a novelty to enter a low, flat-roofed house filled with Queen Pines at the stage of their second swelling. Melons in various stages were growing in similar structures. *Yorkshire Gardener*.

VEGETABLES.

A NEW KALE.

A NEW variety of Kale or Borecole known as Carter's Russian is valuable on account of its hardy nature and good culinary qualities. It is very distinct in habit and is valuable for furnishing a supply of vegetables in winter and early spring when good green vegetables are scarce. Carter's Russian Kale differs from the older form in its deep-cyrt or lacinated foliage and the abundance of useful sprouts which are produced on the stems. The variety is not a tall grower, which is a point in its favour, for it is thus less exposed to winds and is not so liable as taller kinds to be affected by severe weather. The variety has been tried at Wisley in comparison with other Kales, and it has received the high award of a First-Class Certificate from the Royal Horticultural Society. New varieties of green vegetables are not too common, especially those which are in season when most other kinds cannot be had. The culture of this vegetable is simple. For a late supply seeds should be sown in the early summer months on land that has been well prepared, and the seedlings should be thinned or transplanted 2 feet apart both ways. It is a rapid grower, and for an early winter supply I advise a spring sowing so as to enable the plants to be very early planted. But nothing is gained in sowing too early and leaving the plants in the seed beds to become drawn. I have sown the seeds very thinly in rows, dropping them at intervals, thinning out the seedlings when large enough, and thus avoiding transplanting. This system saves some amount of time, and the plants removed can be utilised for a successional crop.

Land on which all kinds of Kales are grown should be dug deeply, but the soil needs no manuring provided it was dressed for a previous shallow-rooting crop. The use of fresh manure is not advised. At the same time if the land is poor it should receive some manurial dressing, which should be placed at a good depth so that the roots can penetrate into it. In planting from seed beds it is best to select young plants and to perform the operation in dull, showery weather. It is also advisable to plant on land that has not recently grown a crop of the Brassica tribe, for when members of the Brassica tribe are planted in succession upon the same site there is a tendency for the land to become infested with the fungus causing clubbing, and this pest is difficult to eradicate. *Geo. Wythie*.

TREES AND SHRUBS.

RHODODENDRON (AZALEA) INDICUM VAR. KEMPFERI.

WHEN Professor Sargent made his notable journey to Japan in the early nineties, the literary outcome of which was the delightful *Forest Flora of Japan*, he found and introduced to cultivation many interesting plants. Amongst these must be counted Kämpfer's variety of the Indian Azalea. In a letter regarding this shrub, Professor Sargent observes that he gathered the seeds from as high elevations and as far north in the mountains as he could find plants growing, "in order to obtain, if possible, a new race likely to be hardy in the New England climate." Some of the seedlings he sent to Kew. The plants, although they have not grown quickly, have proved to be hardy in exposed positions, and a goodly number of them are now in flower. The flowers are singularly variable in colour, some being purplish-rose, some rose-coloured, and some very scarlet. The best of them are really attractive, and form a distinct acquisition. The leaves are similar to those of the greenhouse varieties of *Azalea indica*, being lanceolate or oblanceolate, dark dull green, and covered with bristly hairs; they are, however, considerably smaller. Although hardy enough to have withstood the winters during the last 15 years at Kew, the plants give one the impression that warmer conditions would be acceptable to them. They are of dwarf, compact habit, and plants raised in 1893 are only from 2 to 3 feet high. Given a warm, sheltered spot, and a light, peaty soil, this northern form of the old Indian Azalea is well worth growing in the gardens of the south and west of Britain.

PERIS FORMOSA.

Two species of *Pieris*, *P. floribunda*, and *P. japonica*, are well known in gardens under the generic name of *Andromeda*. In places where they thrive few evergreens are more desirable. This third species, which comes from the Himalayas, is not so well known. In the *Gardeners' Chronicle* for April 30, 1881, there is a very characteristic picture of a flower raceme. Although not inferior in beauty to either of the better known species, it is not so hardy, and to see it at its best in this country, one has to go to the Cornish gardens, where, if I remember rightly, it grows 8 to 10 feet, perhaps more, in height. But that it will succeed in less favourable conditions is shown by a specimen at Kew, which was raised from seed in 1892, and grown to flowering state out-of-doors. The inflorescence is similar in contour and arrangement to that of *P. japonica*, but is much larger. The flowers, too, are larger and more cup-shaped, the whole forming a dense mass of pendent white blossoms. They are like those of the two commoner species but larger; they are broad, lanceolate, 4 to 6 inches long, of leathery texture, and dark green. The shrub is of handsome habit, growing broader than it is high in

open, favourable situations. The same species, or one very nearly allied to it, has been discovered by Mr. E. H. Wilson in Western Hupeh, China. *W. J. B.*

FINE TREES AT HACKWOOD PARK.

A FEW weeks ago Mr. H. J. Clayton referred in these columns to certain trees that were at Hackwood Park, Basingstoke, when he was gardener there in 1866. Of these trees he will regret to learn that the Weeping Turkey Oak has long since been dead. The Douglas Fir, then some 82 feet in height is still there, but, in common with so many of its noble compeers, has been sadly disfigured by hurricanes and snowstorms. It has also lost its leader, yet it is now about 100 feet in height, and the girth of its stem at 2 feet from the ground, which was then 9 feet 3 inches, is now 13 feet, as I found a few days ago when I was enabled to measure it. It is but one of thousands of very lofty Pines and deciduous trees in what are called the "Spring" Woods. The most noteworthy specimen tree in the park, however, is a giant and noble round-headed Beech, which, like a true woodland monarch, "stands in its pride alone" in one portion of the huge pasture area. This is probably at least a tricenarian, and its stem at

first to introduce seeds into that county from New Zealand and to grow it permanently in the open, and it is owing to his generosity that it is now to be met with in almost every garden of note in Cornwall. At the late Temple Show three fine plants in tubs were exhibited by Mr. Enys, which attracted much attention and received a Silver Banksian Medal. With their large shining leaves and numerous blue flower-heads, although these were a little past their best, they formed a handsome group in the garden. There is no comparison between the comparatively weak growth exhibited by pot plants and the vigorous habits manifested by well-grown specimens in the open air, where the plants sometimes attain a height of 3 feet and carry leaves often as much as 2 feet in length and 18 inches in breadth, the foliage suggesting that of the Rhubarb in its noble form and being particularly attractive owing to its bright green tint and glossy surface (see fig. 5). These splendid specimens throw up dozens of branching inflorescences, the flower-heads being often 8 inches in diameter, while the individual blossoms are about half an inch across. There is considerable variation in the colour of the flowers. In the best variety they are of a uniform blue, but in others they are deep blue

wall is intense and the leaves will often flag badly. At Enys a plantation has been made beneath a north wall, and it was looking very promising this spring. When making growth the *Myosotidium* requires a copious water supply. It is fairly hardy, and in a Devon garden has stood 10° of frost unprotected without being harmed. It is generally at its best about the middle of May, and a large group in full bloom at that time presents a glorious picture. *S. W. Fitzherbert.*

FLOWERS OF SPENSER.

(Continued from p. 393.)

BAY.

1. To win a willow bough, whilst other wears the Bay. *F. Q., IV. i. 47.*
2. The Muses that were wont greene bayes to wear. *Shepherds Calendar, November, 147.*
3. Bay leaves between. . . .
Bene they not Bay-branches which they doe beare? *Shepherds Calendar, April, 104.*
4. And by the bay, which I unto her gave,
Accomts myself her captive quite forlorne. *Amoretti, Son. 20.*
5. Compar'd with Myrtle and the Bay. *An Elegy, 1, 18.*

The Bay is a South European plant, but was known to English writers from very early times. "Bay trees are comen in gardenes in the South parte of Englande" (Turner, 1578). But by nearly all the writers of the sixteenth century it is only spoken of as the crown of conquerors, and so it easily came to be spoken of as a synonym of victory. The English name is very ancient, but its descent from the Latin *bacca* (berry) is easily traced.

BEECH.

The warlike Beech.

F. Q., I. i. o.

The Beech is more or less native all over Europe and Western Asia. Its English name in the eighth century was *beoce*, which before long took its present form of Beech. I cannot explain the epithet "warlike."

BELLAMOURES.

Her snowy browes, like budded Bellamoures.

Amoretti, 64.

Spenser uses the same word in *F. Q., II. vi. 16.*

Loe! loe, how brave she decks her bounteous boure
Thereto to shrowd her sumptuous Bellamoure,

but it is very doubtful whether he is speaking of the flower or Nature. The plant has not been identified, and I think it probable that Spenser meant no flower in particular, but more generally any favourite and beautiful flower.

BIRCH.

1. The Birch for shafts. *F. Q., I. i. o.*

2. . . . as a swarme
Of flies upon a birchen bough doth cluster. *F. Q., V. xi. 58.*

Common throughout Europe, and bearing its present English name from the earliest times.

BOX.

And Box yet mindful of his olde offence.

Virgils Gnat, 85.

Though a British tree, the Box seems never to have had a true British name, but to have kept one derived from the Latin *Buxus*. I have never seen a satisfactory explanation of "his olde offence," but suppose it to refer to the legend that the Box was one of the woods from which the Cross was made.

FIG. 5.—*MYOSOTIDIUM NOBILE* FLOWERING IN MR. JOHN D. ENYS' GARDEN, CORNWALL.

3 feet from the ground has a girth of 25 feet; at 10 feet from the ground it throws out some seven or eight gigantic arms or branches. The diameter of the spread of the branches, both north and south and east and west is 108 feet. A thousand persons could easily find seats beneath its ample branches. Close by is an aged but Common English Oak, which carries a good-sized cluster of Mistletoe. This parasite is not common on the Oak, and there seem to be but few specimens in the kingdom similarly infested. *A. D.*

MYOSOTIDIUM NOBILE.

This splendid plant, generally known as the New Zealand Forget-me-not, is a native of Chatham Island. It is only in the south-western counties that the *Myosotidium* can be successfully grown in the open air, glass-culture being indispensable in the colder districts. It was introduced into this country in 1838, and first described in the *Botanical Magazine* in 1839, but for many years was treated solely as a greenhouse plant. Mr. John D. Enys, of Enys, in Cornwall, was the

in the centre fading to white at the edge. At Enys a pure white form is also grown. In its native haunts the *Myosotidium* grows on the sea beach just above high water mark, in the sand forming the shore and close enough to the waves to receive many a scattering of wind-swept spray. At Enys there is a painting showing the *Myosotidium* growing in its native habitat at Chatham Island and margining the sea beach with a line of deep blue. Mr. Enys states that of late years it has suffered much from cattle, and is being rapidly exterminated in its island home. The fact that it there grows in sea sand has led to this being used extensively in its culture in this country. In some cases only a heavy mulch is given over a subsoil of porous compost, but at Menabilly, where it is certainly as well grown as in any other garden, a large hole is made in the ground, a cart is sent down to the beach and filled with sand and this is emptied into the hole, the *Myosotidium* being then planted in it. At Menabilly the plants are grown immediately in front of high walls facing in various directions, and apparently they like a full southern exposure least. In such a site, on scorching summer days, the radiation from the

BRAMBLE.

1. The bush my bed, the bramble was my bowne
Shepherds Calendar, December, 65.
2. Of all the seeds that in my youthe was sowne
Was none but brales and brambles to be mowne.
Id. 113.
3. The Bramble bush, where byrdes of every kinde
To the waters fall their tunes attemper right.
Id. June 7.

3. All in the shadowe of a bushye Breere.
Shepherds Calendar, December 2.

The sweete-breare in the first passage is, of course, our common Sweet Briar; but in the second passage Spenser uses Briar, as all the early writers did, for any Rose-bush, keeping the word Rose of the flower. This was Shakespeare's use of the word, as "in colour like the red rose on triumphant Briar," "from off this Briar pluck a white Rose with me."

BULRUSHES.

To make fine cages for the nightingale
And Baskets of bulrushes was my wont.
Shepherds Calendar, December, 79.

CALAMINT.

And the flowre . . . of calamint and dill.
F. Q., III. ii. 99.

The name is simply the Anglicised form of the Latin *calamintha*, which again is the Latinised form of the Greek *καλαμίνθος*

FIG. 6.—MYOSOTIDIUM NOBILE: FLOWERS BLUE.

Spenser's Bramble is not our Blackberry only, but is the general word for all rough, wild, and especially prickly bushes.

PRIAR.

1. Yet both in flowres doe live, and love thee beare,
The one a Paunce, the other a sweete-beare.
F. Q., III. vi. 17.
2. Youngthes folke now flocken in every where
To gather May Baskets and smelling Breere.
Shepherds Calendar, May.

BROOM.

1. The whyles their beasts there in the budded broomes
Beside them fed, and nipt the tender bloomes.
F. Q., VI. ix. 5.
2. Sweet is the Broome-flowre but yet sowre enough.
Amoretti, Son. XLV.

Our beautiful Broom was a special favourite with all the poets who wrote about shepherds; but it needs no comment.

i.e., beautiful Mint. The name shows its high reputation among the Greeks and Romans, and it was as much valued by the old English herbalists. Parkinson said of it that it was so named because "the smell thereof is so excellent that it is fit for a king's house." It was supposed to be a certain remedy against snake bite, but it is now little thought of in comparison with its nearly the true Mint.

CAMOMILE.

Breathful Camomill.

Maiopotomis, XXVI.

Though the plant has its old Greek name it is a true native, and no plant was more in favour with the old herbalists: "it delights the mind and brings health to the body," said Lawson; and the moralists were fond of using it as the emblem of the excellence of patience. "The more it is trodden on the faster it grows," said Falstaff.

(To be continued.)

The Week's Work.

FRUITS UNDER GLASS.

By T. COOPER, Gardener to Lord Llangattock, The Hendre, Monmouthshire.

Mid-summer Peaches.—In gardens where large houses have been planted with carefully-selected varieties to ripen in succession to each other, a supply of ripe fruits can be obtained over a very long period. Discontinue syringing a tree as soon as its fruits commence to ripen, and carefully examine ripening fruits every evening in order to gather those that are fit. If this is attended to by an experienced man, there will be no need for suspending nets beneath the trees to catch fallen fruits. Commence to syringe the trees again directly all the fruit has been gathered, applying the water with sufficient force to dislodge red spider and thoroughly cleanse the foliage from dust. Thin out the wood also, retaining those shoots best suited to furnish the trees and produce fruit next season. Thoroughly water out-door and in-door borders, and occasionally, until their leaves fall, apply some manurial stimulant to those trees that have yielded heavy crops of fruit.

Strawberries.—There should be no further delay in shifting young layered plants into the pots in which they will fruit. These may vary from 2½ inches to 7 inches in diameter, the smaller pots being convenient for the plants which will be forced earliest. The pots should be thoroughly cleansed, have a piece of wire gauze placed at the base of each to exclude earth worms, and a suitable quantity of drainage material added. A compost consisting of three barrowloads of tolerably heavy loam, one barrowload of dry and well-broken horse-droppings, and an 8-inch potful of soot will answer admirably, and it should be used in a moderately dry and fine condition. Ram the soil well round the roots with a wooden rammer, but not to such an extent that the water will be unable to percolate through it. When the process of potting is completed, place the pots closely together upon a bed of ashes in an exposed position for a week or two so that they may shade each other from powerful sunlight, until the roots again become active, when they may be spaced out to prevent overcrowding. Spray the plants overhead in the morning and evening during fine weather, remove from them any runners as soon as they appear, and give frequent attention to watering.

Scalding of Grapes.—Even in the best-constructed houses some varieties of Grapes, including Lady Downe's Seedling, are liable to become scalded in the presence of strong sunshine; but in smaller, imperfectly-ventilated houses it is the more difficult to prevent this evil. The mischief usually takes place during the time the fruits are forming their stones, and means should be taken to prevent moisture from condensing on the berries. This may be done by keeping the water pipes well warmed, and the houses slightly ventilated at night, increasing the ventilation early in the morning, so that the atmosphere and the berries will become warm at the same time. In certain cases it may be necessary to afford slight shade by the use of such material as fish netting.

Fig trees in borders that have ripened their first crop of fruit may, provided they are healthy, and have during the time the first crop was maturing made firm wood, be allowed to develop a small second crop. Thin the fruits early, and thoroughly cleanse the trees as recommended for pot

Fig trees, but the preparation should not be used at so great a strength as is advised for trees that have finished fruiting. Clear away exhausted mulchings, and replace them with decayed manure. Keep the trees well supplied with diluted liquid manures, or artificial fertilisers, syringe the trees freely in the morning and again at closing time. Ventilate the house early in the day, and maintain a moist, warm atmosphere while the fruits are swelling. When the figs commence to ripen, expose them to full sunlight and ventilate the house more freely; keep the atmosphere dry, but warm.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchard Grower to Lt.-Col. G. L. BULLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Cattleyas and Lælias.—There is not a month in the year in which the flowers of these most important and beautiful Orchids may not be enjoyed, and amongst the late spring and early summer-flowering species and hybrids are some of the most gorgeous flowering kinds. Plants that have flowered, and have since enjoyed a period of rest, are now showing signs of fresh growth. The condition of these plants at the roots should be ascertained, and if any are in need of fresh rooting material the operation should be carried out ere the new roots and growths have greatly increased, thus avoiding injury to the plants. Healthy plants should be repotted with as little root disturbance as is possible, but any having decaying material about their roots should have all the old compost shaken from them, cutting all dead roots away and removing old and useless pseudo-bulbs. Good and ample drainage material is essential for these Orchids, and in the case of large pots to accommodate strong rooting kinds, or extra large plants, a small pot should be inverted over the drainage hole, filling up to and around it with potsherds and lumps of charcoal. In repotting, keep the main growth as near to the centre of the receptacle as is possible, employing a similar compost to that previously advised for Cattleyas. Make the soil firm about the roots. For such robust-growing members as *Lælia purpurata*, *L. tenebrosa* and their progeny, use the rougher of the potting compost with a good admixture of broken crocks and charcoal. This admits of large quantities of water being given, for the plants will need much moisture during their period of active growth. The pseudo-bulbs should be firmly secured to stakes until the new roots form a natural support.

Late summer and autumn-flowering Cattleyas.—*Cattleya superba*, *C. Gaskelliana*, *C. gigas*, *C. aurea*, *C. labiata*, *C. Harrisoni* and their hybrids, *C. Lord Rothschild*, *C. mollis*, *C. Ashtoniana*, *C. Pittiana*, *C. Cleopatra*, *C. Macanensis*, *C. Fabia*, *C. Hardyana*, &c., are all now growing freely, and some are forming their pseudo-bulbs. From this stage the plants will enjoy a liberal treatment, and they should be given a position in the house where they may have the full benefit of light and air. The majority of the plants named produce their flower-spikes ere the season's growths are completed, therefore a stint of water at the roots must occur until the new pseudo-bulbs are fully matured.

Lælia Dichroma.—Plants of this distinct species are now flowering in the Cattleya house. Shortly after the flowers are removed, the last formed pseudo-bulbs emit new roots from their bases, and before this takes place any necessary repotting should be done. As these plants are best grown suspended from the roof-rafters, pans are the most suitable receptacles. These should not be over-large, as the best results are attained when the roots are confined; the drainage must be ample, and the potting materials moderate in quantity. Newly-potted plants require careful watering, only just sufficient water to maintain the new material in a moist condition being necessary. When re-established, treat them in the same manner as those plants which have not been disturbed at the roots, viz., suspend them together in the lightest position of the Cattleya house, and afford them a long period of rest, during which time water sufficient only to keep the pseudo-bulbs from shrivelling and the roots in a healthy state is needed.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The Downage Lady, Nuneham House, Water Ferry, Wiltshire.

Watering and mulching.—The timely watering of borders in which Apricot, Peach, Pear, and other fruit trees are planted is of the highest importance, and the trouble is well repaid in the improved quality of the fruit, extra vigour in the foliage, and healthier conditions in the tree generally. In many parts of the country the rainfall has been inadequate for fruit trees, especially in the case of those growing in borders which are very freely drained. The timely mulching of the trees, as was recommended in the Calendar for May 30, will do much to conserve the moisture in the soil, but even when a layer of manure has been applied to the surface of the soil, attention must be given to watering, for on no account must the roots be allowed to become dry when the fruits are swelling and the stones of stone fruits forming. Apricot trees especially are affected by drought, and on no account should they lack moisture at this stage. Diluted liquid manure should be given to any trees that require a stimulant, and to such as are carrying heavy crops of fruit. The liquid manure should be given alternately with the ordinary watering. If liquid manure is not available, a small dressing of some artificial manure will form a good substitute. Avoid overcropping the trees, as nothing is gained thereby, and the trees are sure to suffer later if their energies are overtaxed. Newly-planted trees, and especially those that were planted late this spring, will require attention, particularly in affording moisture at their roots. Liquid manure should not be given in the case of young and newly-planted trees which are growing satisfactorily, as it will only tend to make them develop extra vigorous growths, and coarseness of wood is not conducive to fruitfulness. Stir the surface of the soil with a fork in all cases before applying a mulch or water to the roots.

Summer training.—Continue to secure and regulate the shoots of Peaches, Nectarines, Pears, &c., according to the system of training adopted. At the same time thin the fruits, leaving only the centre one in each cluster. Large culinary varieties of Apples, such as Bismarck, Bramley's Seedling, Gascoyne's Scarlet Seedling, and Peasgood's Nonsuch should have their fruits thinned freely; in fact, all varieties of Apple are improved by judicious thinning when the fruits have set too thickly. On the evenings of fine, dry days, with the garden engine or hose thoroughly wash all dirt and traces of insects from the shoots as soon as they have been regulated and tied. Occasionally an insecticide should be applied to the foliage. Summer pruning must be practised in the case of all fruit trees, not only those growing against walls and espaliers, but also pyramid, bush, and other trees, as the young, lateral growths not only rob them of nourishment, but also exclude light and air from the fruit buds on the spur shoots.

THE KITCHEN GARDEN.

By F. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Ebbw Vale, Hertfordshire.

Weeds.—Every opportunity should be taken to clear the ground of weeds, which must never be allowed to develop their seeds. The garden fire should now be kept going regularly, for it is better to burn weeds and other rubbish than to allow it to remain about the garden. The ashes form a valuable material for dressing the soil.

Watering and hoeing.—Land that has been deeply worked and well enriched with manure will suffer little from drought, especially if mulchings have been applied, as previously advised. When watering is necessary it should be done thoroughly, and the work should be performed as far as practicable during the late afternoon or evening. The stirring of the soil by means of the hoe is a most valuable operation, not only as a means of destroying weeds, but also for conserving the moisture in the soil during seasons of drought. The Dutch or draw hoe may be used, and they are alike valuable on both heavy and light soils at this season.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JULY 4.—
Soc. Franc. d'Hort. de Londres meet. German Gard. Soc. meet.

TUESDAY, JULY 7.—
Roy. Hort. Soc. Summer Exh. at Holland Park (2 days).
Wolverhampton Floral Fete (3 days). Nat. Amateur Gard. Assoc. meet. Bath Rose Sh. (2 days).

WEDNESDAY, JULY 8.—Croydon Flower Sh.

THURSDAY, JULY 9.—
Newmarket Fl. Sh. Cambridge Fl. Sh.

SATURDAY, JULY 11.—
Folgate and Little Stanore Hort. Soc. Exhibition.

AVERAGE MEAN TEMPERATURES for the ENSUING WEEK, deduced from observations during the last fifty years at Greenwich.—62.9°.

A-14-Hour TEMPERATURES.—
LONDON.—(Wednesday, July 1 (6 P.M.)) Max. 78 Min. 54°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London. (Thursday, July 2 (10 A.M.)) Bar. 30.3; Temp. 78°; H. rather bright sunshine.

PROVINCES.—(Wednesday, July 1 (6 P.M.)) Max. 72° (Christchurch); Min. 61° (Lancaster).

SALES FOR THE ENSUING WEEK.

WEDNESDAY.—
The new *Pendroblum* region just to hand, also a grand new *Frederic* and flowering Orchids. Established Orchids, &c., at 67 & 68, Chispeade, E.C., by Protheroe & Morris, at 2.

The Gardeners' Beneficent.

The need of this Charity for increased support was again forcibly pointed out at the sixty-ninth anniversary dinner that took place on the 24th ult. In his speech to the toast of "the Gardeners' Royal Beneficent Institution," Lord Aldenham, who occupied the chair on this occasion, stated that the annual expenditure necessary, for the maintenance of the 231 pensioners now on the funds is about £4,000, and that the assured income amounts only to £1,500, leaving therefore a balance of £2,500 to be raised by voluntary subscriptions. Most of our readers are already aware of these circumstances, but we make no apology for restating them, because it is imperative that their importance shall be thoroughly understood and appreciated. There are also other facts that must be considered with the figures already cited, and Mr. Harry J. Veitch who, as treasurer and chairman of the Executive Committee, has devoted enthusiastic work in aid of the Institution for so many years, very appropriately directed attention to them.

The sum of £4,000 is needed to support the pensioners who already obtain their means of subsistence from the Institution, but how much additional help is needed can be approximately estimated by the knowledge that at each annual election it is only possible to elect about one-half the number of deserving applicants. Thirty candidates failed in their appeal for support at the last election, and if it is found impossible to elect a larger number of new applicants each year in the future than at present, many of these may have to wait three years before they are successful. It is true that there is the Victoria Era Fund, which assisted 22 cases last year, and also the Good Samaritan Fund, which assisted in 33 cases last year—the former affording help to candidates awaiting election who have been subscribers to the Institution, whilst the latter assists applicants who have never themselves contributed. An infinite amount of good is done by these means, but, valuable as these funds are, they are incapable of affording the assistance to the candidates that would be forthcoming if the income of the Institution permitted of their election as pensioners without having to wait for so long a period.

Lord Aldenham reminded his hearers of some of the principal events in the history of the Institution, how it was established nearly seventy years ago, and how in 1879 our present King became President and remained in that office until his accession to the throne, when he was succeeded by the Prince of Wales. His Majesty himself became a generous patron. Every year some influential nobleman or gentleman has pleaded the claim of the Institution at the festival dinners, and the general management and administration of the funds have been so perfect as to comment the Charity to all who have taken any trouble to enquire into the details.

Last week there was instituted in the City of London an association of subscribers to charitable institutions, which has been rendered necessary by circumstances—such as overlapping, connected with the management of certain organisations. There is no overlapping in this case; the expenses of management are kept as low as possible, and they are more than covered by interests derived from invested funds.

Since its establishment a sum of nearly £122,000 has been distributed to necessitous gardeners and their widows, and how much suffering must this have prevented or mitigated!

Although maintaining its character as a beneficent institution, the rules so far encourage thrift that for every pound contributed to the funds a subscriber is given 100 votes in the event of his having to apply for relief. This has the effect of placing the subscriber in a much more favourable position than those who have failed to contribute; and, as a matter of fact, if he has paid subscriptions for a few years it makes his ultimate election certain.

Mr. Veitch referred to the unsectarian character of the Institution. No enquiries are made as to a candidate's religion, but strict investigation as to his moral character is insisted upon. An applicant must not have an assured income of more than £30 a year.

and, as Mr. Veitch said, many of the pensioners possess nothing at all beyond the assistance the Institution is able to afford them. The committee consists of thirty-six members, one-third of whom are always composed of practical gardeners, the remaining two-thirds being made up of amateurs and others connected in various ways with horticulture. At present there are three pensioners over 90 years of age, and 53 between 80 and 90 years. The oldest is a widow aged 95. She has been on the funds for a period of 22 years. Another widow is the person who has been a pensioner for the longest period, and she succeeded her husband, who during his life contributed about £20 to the Institution.

In addition to the contributions from annual subscribers, the Institution receives financial help from various sources, some of which were pointed out by Mr. Veitch, who particularly mentioned Mr. N. N. Sherwood, whose presence at this event everyone was pleased to note as indicating recovery from a very long period of indisposition. Thanks were accorded to Mary Countess of Ilchester for her kindness in throwing open the Holland House Gardens on the occasion of the annual exhibition in the park; also to Sir Frank Crisp and Lord Beauchamp for sums obtained from visitors to their gardens; to the George Monro Concert Committee and the local Auxiliaries. In this connection we cannot help thinking that very much more might be done to raise money at the competitive exhibitions that are held in every part of the country, and especially at some of the principal ones where considerable sums are made every year by means of horticultural exhibits, should the committees feel themselves in duty bound to subscribe to the gardening charities. Some of them recognise this duty in a liberal spirit, but in a case upon which we remarked on page 403, whilst a sum of £2,682 had been given to various charities by a gala committee, only £62 ros. was listed as contributed to the "Gardeners' Orphan Fund, &c." But it appears that the exact sum the Orphan Fund has received from that source is £5, whilst the Gardeners' Royal Beneficent Institution has received nothing!

We earnestly ask all to remember Mr. Veitch's words when speaking of losses the Institution sustains by death. Circumstances change very rapidly in these days, but the widow and the necessitous are always with us. Shall they appeal in vain? If the Gardeners' Royal Beneficent Institution should unfortunately fail in the work it is now doing, many gardeners and gardeners' widows would have to seek an asylum in the workhouse. We are perfectly sure that all who have horticultural sympathies will refuse to entertain such a possibility. To prevent this, everyone must do what in his power lies to increase the income of the Gardeners' Royal Beneficent Institution.

We were able to announce in our last issue the sum raised in connection with the dinner amounted to a little over £2,000. It only remains for us to remark that pleasant features of that meeting were the presence of several gentlemen from New Zealand and Australia, and a sympathetic and complimentary speech delivered by Mons. Vig er, President of the Soci t  Nationale d'Horticulture de France.

Zanzibar Anime or Copal.

The researches of Sir John Kirk in Eastern tropical Africa, both during the time he was attached to the Livingstone expedition and during his official residence in Zanzibar, resulted in many discoveries proving the sources of some of the most important economic products of that part of the African Continent, and not the least among these was the clearing up of the doubts that had previously existed as to the source of Zanzibar Copal or Anime, not only by specimens of the plants themselves, but also by the careful collecting of a series of specimens of the fossil and recently-formed resins, many of which contained well-preserved examples of leaves and flowers of the tree producing them, the exuding resin having in its soft state enclosed the leaves and flowers, and finally, on hardening, preserved them in the most perfect condition. From these, and other sources of proof, it became clear that Zanzibar Anime or Copal was yielded by *Trachylobium Horremanianum*, and further that the best quality of the so-called gum was that which was found deposited in the ground where the trees themselves no longer existed, and where the resin had become semi-fossilized. Under the commercial name of Anime, this resin is the most valuable and most important of all the resins used in the making of varnish, the best of the hard varnishes, such as are used for carriage panels, being made from it, and often realising in its raw state as much as £400 per ton.

As an illustration of the extent to which all parts of the trees are charged with the resin, it may be stated that the fruits or pods are covered with numerous tubercles, which, in the dried specimens, are found to be composed of solid masses of resin. Hitherto no attention has been paid to these fruits as a source of Copal, but in an article recently published in Germany on the Copal trade in German East Africa it is stated that the fossil resin, which was formerly collected on a large scale by the native population, has, since the suppression of the slave trade, been entirely neglected, with the result that there is a scarcity of this kind of Copal. A patented process has, however, been established for extracting the Copal from the fruits, which is said to amount to 23 per cent. and to be of an exceedingly good quality for the manufacture of hard out-door varnish.

OUR SUPPLEMENTARY ILLUSTRATION

shows a tree of *Catalpa bignonioides* in flower in Lt.-Col. HOLBORN'S garden at Westnort, Gloucestershire. This beautiful American tree is fairly common in favourable localities in this country, but it is not frequently seen in profuse flower, the blooming depending in a great measure upon the weather of the previous summer and autumn and the absence of severe spring frosts. Still less frequently is it seen in fruit, but the specimen under notice was laden with its seed pods after the flowers had fallen. *Catalpa bignonioides* was introduced into this country in 1728, and one of the oldest specimens was, and perhaps is still, to be found in the gardens of Gray's Inn, in the City of London. The tree is little affected by the smoke and other deleterious matter present in the atmosphere of large towns, and for this reason, as it is so handsome when in leaf, it is one of our best town trees, but its claims to recognition in

this respect have been neglected, for it is not nearly so often used for street planting as it might be. The tree is a beautiful object when in flower; we remember being greatly impressed with the specimen at the back of the Council Room in the old Chiswick Gardens on our first seeing it in bloom. For beauty the individual blossoms can rival a delicately tinted Orchid. Lat, then, all the flowers of the Bignoniaceæ are handsome, although not many are hardy in this country. *Catalpa bignonioides* is found wild on the banks of the Ohio and Mississippi Rivers; its timber is valued in those regions on account of its durability in the soil, which renders it valuable for the making of posts and railway ties.

HOLLAND HOUSE SHOW.—The Royal Horticultural Society's summer exhibition will again be held this year in the beautiful grounds attached to Holland House, Kensington, by permission of MARY Countess of ILCHESTER. The exhibition will continue open for two days, viz., July 7 and 8, Tuesday and Wednesday. Amongst the prizes offered is the silver cup given by N. H. SHERWOOD, Esq., and this year offered for the best 24 bunches of Roses with their foliage, shown by an amateur. Although the summer exhibition of the R.H.S. does not rank in importance as equal to the Temple Flower Show, it is always a fine display, and the visitor can move about with comfort, for the space is ample. For this reason many persons may prefer to visit the Holland House shows rather than to endure the crowding and fatigue involved in a visit to the Temple.

FLOWERS IN SEASON.—Flowers of *Sarracenia purpurea* and spikes of the Cotton Grass (*Eriophorum angustifolium*) are sent us by Mr. W. A. COOK from Sir EDMUND LODER'S noted garden at Leonardslee, where the *Sarracenia* grows in large clumps in the open, and at this season flowers with freedom. The Cotton Sedge is a native species, its silken tassels, by means of which the fruits are dispersed, appearing like a tuft of cotton-wool; it forms a pretty combination with the crimson flowers of the *Sarracenia*s. These latter plants flower regularly every season and ripen their seeds effectually and freely. The *Drosera* and the *Pinguicula* also grow freely around these beds. *Darlingtonias* are in flower; but these do not bloom with the same freedom as the *Sarracenia*s, which have been established for a quarter of a century at Leonardslee, where many young plants have been raised and are flourishing. Hardy *Cypripedium*s have flowered well, especially *C. acaule*.

THE NATIONAL SWEET PEA SOCIETY'S annual exhibition, of which the show this year will be the eighth, takes place on Friday, July 24, in the Royal Horticultural Hall, Westminster. The date is the only one on which the hall is available from July 3, and although fears were entertained that it might prove late, especially for southern growers, the backward season has regulated things so that there is every prospect of another beautiful display of this increasingly popular flower being seen. The schedule is arranged to suit all classes of growers; the prizes include many cups, in addition to medals and money, and these trophies are fairly distributed through the various sections into which the classes are divided. The hon. sec. is Mr. C. H. CURTIS, Adelaide Road, Brentford, Middlesex.

It was arranged that the members of this Society should visit Messrs. DOBBIE'S Seed Farm at Marks Tey as soon as the Sweet Peas were in good bloom. Mr. SHERWOOD, sen., of Messrs. HURST & SON, has expressed a wish that the members should also visit his grounds.

Arrangements have been made to visit both these establishments at the end of next week. Those desirous of joining the party, and who have not already communicated with the hon. sec., are requested to do so immediately.

RAILWAY STATIONS AND FLOWERS.—Travelers in Belgium must have been struck, during the last year or two, by the improvement introduced into the railway stations by the floral displays that meet the eye. It appears, according to a writer in *La Tribune Horticole*, that the change is due to the efforts of a highly placed official of the Belgian Railways, and the co-operation of a member of the staff of the Botanic Gardens of Brussels has resulted in the issue to the station-masters of a booklet containing precise information as to the selection and methods of culture of plants suitable for the purpose. The idea was first started in 1905, and this year about 600 station-masters are assisting in the efforts to brighten the stations with flowers. We in England have long been accustomed to see many of our country stations tastefully decorated with flower borders, and several of the railway companies give every encouragement to their employes in this connection. It is an excellent practice, and one which everyone would wish to see more widely adopted.

PRESERVATIVE EFFECT OF ROADSIDE TREES.

—In the *American Florist* we read that in answer to enquiries from the United States Consul-General ROBERT P. SKINNER, of Marseilles, furnishes the following information relative to the effect of wayside trees on French roads: "It is proposed to plant trees along the roadsides of New York State in order to keep the moisture in the road and prevent travelling, and the question has been raised whether or not the roots of such trees may spread out underneath the road surface and eventually create great damage in a severe climate where there are extremes of heat and cold. While French roads are not always bordered with shade trees, they are so very frequently, and my information is that the trees are planted not only for furnishing shade, but in order to protect the roads themselves against the effects of excessive heat and drought. It is believed that the long dry summer season is much more inimical to roads than severe cold. The chief officer in charge of the public roads in Marseilles is of the opinion that, on the whole, New York roads would be benefited if bordered with trees, suggesting, however, that only such should be planted as have vertically descending roots." F. BIKOR, civil engineer and former conductor of the bureau of bridges and highways, expresses himself as follows on the subject: "In countries where the climate is damp, roadside trees are prejudicial to the maintenance of the highways, as they prevent the circulation of the air and the drying of the soil; in most of the southern French regions such plantations are, on the other hand, very useful in dry weather, as they maintain the roadbed in a state of freshness favourable to its conservation. In general, trees should be selected with high, spreading branches, such as the Poplar, the Elm, and the Ash, and they should be planted generally upon the outer edge of the road-box and at distances of 10 metres (32.80 feet). Each tree should be placed in a hole 1 metre (3.28 feet) deep and 1½ metres (4.92 feet) square, and should be trimmed to a height of 2½ metres (8.20 feet) above the surface. The earth about newly-planted trees should be loosened in March and November — in March only after the third year — and thereafter until their permanent growth appears assured; small trenches should be directed toward the foot of the tree, in order to secure the benefit of rains. Finally, the tree itself should be trimmed annually during the first 10 years."

THE NEILL MEOALIST.—The Neill prize, under the late Dr. PATRICK NEILL'S will, is a reward in the gift of the Royal Caledonian Horticultural Society, awarded every second year to a distinguished Scottish botanist or cultivator, and this year it has been awarded to JOHN H. WILSON, D.Sc., F.R.S.E., Lecturer in Agriculture and Rural Economy at St. Andrews University. Dr. WILSON could scarcely help having a bent for horticulture and botany, since he was brought up from his earliest days amongst plants. The profession of horticulture had many attractions for him, and in it, as well as the pursuit of field and garden botany, he got as good a grounding as any son of an enthusiastic father could wish. On leaving home he spent a few years in the Royal Botanic Gardens, Edinburgh. Laying aside the tools, he entered the botany classes of the University of Edinburgh, and had the satisfaction of finding himself before long first prizeman in the theoretical and practical classes. He then returned to his native city, St. Andrews, entered on a course of study for a science degree, and in due time graduated B.Sc. Shortly after graduating, he gave a course of lectures on botany in St. Andrews University, and the following session he was appointed as the first University Lecturer on botany there. In order to widen his botanical knowledge, he accepted an invitation to take charge of the herbarium in the Royal Botanic Gardens, Edinburgh, and having spent some time there he again entered the University of Edinburgh, his object being to improve the agricultural side of his education. He was appointed Lecturer on Agriculture in the University of St. Andrews in 1900. Immediately after being appointed, he made a journey across the United States to California, returning by Canada with the view of observing the methods followed in the teaching of agriculture and allied subjects in America. On his return he set about instituting long-delayed experiments in hybridisation of farm plants, and this work has gone on continuously ever since.

CHINESE VITICULTURE.—Apart from being the centre of fruit culture in China, the province of Shantung produces large quantities of fine Grapes, and promises soon to become a very important wine-making district. In the neighbourhood of Tsingtan, mainly on the southern slopes of the Laushan Mountains, many Grapes are grown for the fruit only. Large quantities are now sent to Shanghai and other places annually, a variety closely resembling the Californian "tokay" predominating. White Grapes are also grown, a sort of "sweetwater," and a kind called "Marcobrunner" being the most common, but blue and Black Grapes are not found. Apparently no attempt to produce wine has been made here, but in North-Eastern Shantung, the industry has made some progress, according to the American Vice-Consul of Tsingtan. On the hills surrounding that city are many terraced vineyards, and an extensive wine-making establishment has been in operation for years. It is stated that white wines and red wines, and champagnes of many varieties are made, but none of the products have yet been placed on the market. Concerning the wine-making establishment at Chefoo, a wealthy Chinaman, about 10 years ago, conceived the idea of cultivating Grapes in China for the purpose of an extensive wine trade. Land was bought on the hills near Chefoo and planted with varieties of Grapes from all wine-producing countries, under the direction of a European expert, who is still in charge. More land is constantly being acquired in the immediate vicinity, and planted as soon as bought, but the price of suitable territory has gone up considerably. Phylloxera is stated to have attacked

some of the varieties, but never to a disastrous extent, most of the vines appearing to be immune. Each autumn the entire crop is taken to the wine-making establishment on the outskirts of the town, and after production the wine is stored in large casks, constructed in sections in Austria, shipped to Chefoo, and set up in the cellars. Every barrel is plainly marked with the variety of wine it contains, together with the year of its production. The cellars, started four years ago, took two years to complete, and are built below the level of the sea. They are lined with concrete, as it was found that they were otherwise being constantly flooded. There is now a large supply of wine on hand, but it is stated that the first sales are not to be made until the end of 1908 or in 1909. The market is to be exclusively the Chinese coast, but the leaders of the enterprise do not say what the prices will be, but considering the amount of the investment, a low price is not to be expected. *Journal of the Royal Society of Arts, June 12.*

ALPINE GARDENERS.—The third Congress of Alpine Gardeners, which should have taken place in 1908 at the Col du Lautaret, in Dauphiny, Hautes Alpes, has been postponed to a later date, owing to the death of Professor LACHMANN, director of the Alpine Gardens of Lautaret and Chamrousse. *Société Botanique de France.*

A NEW RUBBER TREE.—M. MARCEL DUBARD, writing in *Le Caoutchouc et la Gutta Percha*, announces the discovery of a new Rubber tree which exists in large quantities in the forests of Tonkin. The tree is a species of *Bleekrodia*, a member of the *Urticaceae*, a family which furnishes many rubber-producing plants. The rubber from *Bleekrodia* is said to be of excellent quality and equal to the best Para.

HOT WATER AND EARLY FLOWERING.—Prof. HANS MOLISCH has recently been experimenting on the effect of hot water as a means of inducing forced plants to flower earlier than their normal period, and he has obtained some interesting and suggestive results. He finds that when the stems of Lilac, for example, are plunged for six hours in water heated to 30° to 40° C. (86° to 104° F.) under appropriate conditions, that the plants push their buds some 10 days earlier than those not so treated. It seems that whilst the plants have to be experimented on during the resting season, it makes a difference whether this is done early or late in the winter. Very little effect is produced if the treatment is given just after the fall of the leaf in autumn, and, again, if it is delayed until February or March, when the season for the untolding of the buds is approaching, retardation may be the result. MOLISCH obtained the best effects by treating the plants in December or January, and that different temperatures are required by different species. Thus for Lilac and Forsythia, 86° F. is the best, whilst about 100° F. is the optimum for Silver Birch and Chestnut. It is very remarkable that the effect of the treatment is strictly localised. Thus if a Lilac be taken, and certain branches only of the plant be immersed in the hot water, it is found when the plants are forced in the spring that these branches are the first to bear leaves and flowers. Of course, it has long been known to practical gardeners that the branch of a vine trained under glass shoots much earlier than the remainder of the vine if this be grown outside. Possibly, the two cases are analogous, though the results obtained by Prof. MOLISCH are more striking. The matter is obviously worth fully investigating, as it presents an interesting problem in vegetable physiology.

CRICKET AT EAST BURNHAM PARK.—Some 50 members of the various committees of the Royal Horticultural Society visited East Burnham Park, Bucks, the residence of Mr. and Mrs. HARRY VEITCH, on Friday, June 26. The weather was glorious; brakes met the bulk of the party at Slough in the morning, and upon arrival at East Burnham Park they inspected the gardens, which were gay with Roses and other flowers in abundance. After partaking of luncheon, sides of 10 each were formed for cricket, Messrs. W. HORNE and PAGE being the respective captains. Mr. HORNE won the toss, and elected to bat first, and his team was not dismissed until the large score of 111 runs had been made. Of these, Mr. BILNEY made no fewer than 36, his best supporter being Mr. McBEAN, who scored 26. On the other side taking the wicket, there were some short hits, the best scores being those of Mr. C. PEARSON (14), and Mr. F. READER (9). Mr. BILNEY caught or bowled no fewer than six of his opponents, whose total number of runs was 33. After tea, bowls were indulged in on the lawn.

SWANLEY HORTICULTURAL COLLEGE.—The Countess of BEVIE will present the prizes at this college on Tuesday, July 14. The Hon. Sir JOHN COCKBURN, K.C.M.G., Chairman of the Governors, will take the chair at 4 p.m.

TWO LESSER-KNOWN VEGETABLES.—In this country we are apt to be very conservative in selecting the vegetables we consume. Although one occasionally sees the tubers of *Stachys tubifera* exposed for sale, the plant is not so generally grown as it deserves. It is of the easiest possible culture, and, indeed, spreads rapidly unless it is kept in check. It succeeds well in most soils, and with a little attention yields a crop of tubers that possess a characteristic and, to many people, a very agreeable flavour. *Oxalis crenulata*, a South American plant, also forms tuberous rhizomes, and is grown in France, where it succeeds best in a light rich soil. It is, however, a rather delicate subject, and is easily killed by frost. It requires protection when the tubers are first planted in March, until danger of frost is over, and as the young stems are formed they need to be earthed up at their base, leaving the ends uncovered. The tubers swell rather late in the season, and are dug up when the aerial parts have died off. A yellow and a red variety of the plant are cultivated, as well as an inferior sort with white tubers. When the tubers are first gathered they are apt to possess an acid flavour, which, however, disappears on exposing them for a few days to the sun.

A DENDROLOGICAL SOCIETY has been founded in Austria, under the patronage of the Archduke FRANZ FERDINAND, to encourage the spread of knowledge concerning trees and shrubs. It is under the presidency of Count SILVA TAROUCA, and all people who are interested in dendrological matters, whether as growers or amateurs, are invited to become members. It is hoped by the officers that there will be an important foreign membership. The subscription is 20 fr. (about 16s. 8d.) per annum, and the address of the society is Schautergasse 6, Vienna.

HELICONIAS.

ASIATIC SPECIES.

We extract the following instructive article by Mr. H. N. Ridley, M.A., F.R.S., from the *Agricultural Bulletin of the Straits and Federated Malay States* for April last. The Heliconias are now cultivated much more commonly than formerly, but our knowledge of them is very incomplete.

The beautiful plants known as Heliconias so commonly cultivated in tropical gardens belong to the large order of Scitamineae, and to the section Musaceae. The genus is largely represented in America, between thirty or forty kinds being known, but there are also several species, and those among the most popular in cultivation, which are indigenous to the Polynesian islands as far west as Amboina. By some extraordinary error these, or most of these Asiatic species, have been considered by Schumann (in the *Pflanzenreich, Musaceae*, p. 36) as escaped forms of the utterly dissimilar *H. Bihai*, L. of the West Indies. Nicholson, in the supplement to *Dictionary of Gardening*, boldly says that *H. aureo-striata* and other species well known in cultivation are not Heliconias at all, but till now is known of them had better be left among the plants of this genus.

Nearly all the ornamental Asiatic and Polynesian species in cultivation have flowered in the Singapore Botanic Gardens, and prove to be utterly different from *H. Bihai*, L. and very distinct species. The whole genus may be said to be in a distinctly chaotic state, and the descriptions as published in the *Pflanzenreich* are too meagre for the most part for anyone to identify the species. A few species have been flowered in the Kew Conservatories, and are figured in the *Botanical Magazine*. These are chiefly Brazilian or West Indian species. Unfortunately, however, the whole of the literature on these plants is not accessible to me here, and many of the Asiatic species have been introduced without accurate localities being given, having been treated apparently always as forms of *H. Bihai* and simply all lumped together.

Heliconias have always been favourite plants or cultivation here, and used to form a very conspicuous feature of our horticultural exhibitions, the most popular being the beautiful *H. illustris*, Bull. (commonly known here as *H. rubro-striata*) and *H. aureo-striata*. The plants are readily propagated by breaking up the clump, and taking off shoots in the same way as is done for Bananas. Occasionally they produce ripe seed, but that is not very common. They are cultivated as pot plants, in good soil or in shady spots on lawns, where they often form magnificent clumps. They do not usually grow well if exposed to full sun. Like Bananas they require a rich soil, and do not succeed in stiff clay or poor soil, becoming dwarfed and shabby looking. They seem to be remarkably free from pests of any kind, even that troublesome Banana pest, the butterfly *Eriocranta thrax*, the caterpillars of which roll up and destroy the leaves of Bananas and Palms, does not attack them.

THE ASIATIC SPECIES.

In the case of most of the Heliconias from the Polynesian and Malay region, the plants having been introduced as cultivated plants, few or no actual localities have been recorded, so that at present we are ignorant of their place of origin. Mr. Baker in a paper on these plants in the *Annals of Botany* states that he has seen specimens from various localities such as New Caledonia, Solomon Islands, &c., but the unfortunate error which attributed all these distinct species to cultivated forms of the Brazilian *H. Bihai* has prevented his localising or identifying the species he had at hand.

The following is a list of what I presume to be Asiatic species, but they can only be properly worked up and systematised in Europe where there are localised specimens, original drawings, and the literature of the species in different museums:—

- Heliconia indica*, Lam. Loc. ... uncertain
- H. buccinata*, Roxb. ... Amboina
- Heliconiopsis Amboinensis*, Miq. ...
- H. austro-caledoniae*, Vicill. ... New Caledonia
- H. aureo-striata*, Bull. ... uncertain
- H. illustris*, Bull. ... uncertain
- H. rubro-striata*, Hort. ...
- H. triumphans*, Lind. ... Sumatra
- H. spectabilis*, Lind. ... South Seas
- H. Micholitzii*, Ridl. ... New Ireland
- H. viridis*, Nicholson ... Polynesia
- Possibly also *H. striata*, Veitch.

H. buccinata, Roxb., is described as an immense beautiful bush, leaves 2 to 4 feet long and 1-foot broad, petiole 3 to 6 feet long, inflorescence compound of 6 to 10 branches with 6 to 10 smooth bracts, flowers pale yellow, Amboina.

This plant was cultivated in the Calcutta Gardens in 1798, and is identified by Roxburgh with a plant described and figured by Rumph *Herb. Amboin V.*, 141, t. 62, fig. 2, under the name of *Folium buccinatum asperum*. Rumph describes three species in Amboina under the names of *latifolium* or *rubrum*, *album* and *asperum* he gives as an Amboinese name Rind. *Ruin* and *Riin*; *latifolium* being *Rind Mera*; *album* *Rind Puteh*; and *asperum*, *Rind Laki*. Of the red one he says the leaves and leafstalks become red when grown in the shade. This may be one of the red-leaved ones we cultivate, but the description is too incomplete.

H. AUREO-STRIATA, Bull.—A tufted plant, about 5 feet tall. Leaves elliptic acute, base oblique not decurrent, 2 feet to 2½ feet long by 8 to 10 inches wide, nerves 3-10 inch apart, when young green streaked transversely with yellow, adults plain light green dull, petiole 1½ to 2 feet long green. Inflorescence of three or four bracts on a short peduncle, all glabrous. Bracts long acuminate rather narrow the lowest one, 7 inches long including the rather narrow leaf-like portion, upper ones 6 inches, green. Flowers fairly numerous. Bracteole lanceolate acuminate pale green 3 inches long. Ovary narrowed into pedicel in flower 1 inch long with pedicel, orange. Perianth 1½ inch long curved orange at base passing into white sepals lanceolate acuminate acute. Stamens long. Anthers linear acuminate. Staminode ovate. Fruit ½ inch long, obconic 3 angled, orange. Native country not known.

H. ILLUSTRIS, Bull. (*H. rubro-striata*, Hort.).—A large tufted plant, with stems flattened 4 feet tall, 3 inches wide green, petiole 2 feet long and 1 inch thick, reddish to pink or plain green, blade 5 feet long 8 inches across oblong, narrowed at the base so as to be shortly decurrent on the petiole above dark green above with a coppery lustre beneath, midrib channelled on the upper surface pink, edge of blade red, nerves conspicuous ½ an inch apart elevated on the upper surface; young leaves elliptic rather abruptly rounded and only shortly decurrent, dark green with numerous and close rose-pink or often white streaks above midrib green almost disappearing before the tip, back of leaf bright rose-pink with green streaks. Inflorescence about 8 or 9 inches long, rachis green finely pubescent. Boat-shaped bracts 4 to 5, the lowest tipped with an ovate acute blade resembling the leaf in colour, the others with or without a small blade, green pubescent tipped red 7-6 inches long. Flowers numerous in each bract. Bracteole lanceolate acuminate acute 3 inches long. Flowers shortly pedicelled, pedicel thick white glabrous ¼ of an inch long, ovary as long flattened on the inner side yellowish, red in the upper part. Sepal greenish to creamy yellow base and apex red, lanceolate acuminate acute 2 inches long. Petals narrower and shorter similarly coloured. Stamens white connate at the base. Staminode ½ an inch long lanceolate rather broad channelled. Fruit red ½ inch long.

H. SPECTABILIS, Lind. Ill. Hort., 1892, pl. 156.—Whole plant about 12 feet tall. Leaves linear-oblong acute, narrowed to base, margins undulate, nerves about 1 to 1½ inch apart conspicuous midrib thick coppery-red, beneath, deep purple above, occasionally turning green 4 feet 10 inches long 11 inches wide, petiole sheathing for nearly all its length long green or yellowish mottled and dotted with greyish-green. Inflorescence 8 inches long, rachis flexuous velvety pubescent. Bracts 6 lanceolate acuminate pubescent ribbed when dry, ochraceous passing into red 6 inches long 1 inch deep, distant from each other 1 inch. Flowers numerous, pedicels ½ inch long glabrous. Perianth 1½ inch long curved acuminate greenish and red. Sepals ½ inch wide. Filament of stamen rather stout, another linear, staminode oblong truncate ½ long. Introduced in 1891 by Linden from "Asia."

H. MICHOELITZII, n. sp.—A very large plant forming large tufts, stems 2 feet or more tall 3 inches across, pale green marbled with grey. Leaves plain green, blade about 3 feet long, 11 inches across. Inflorescence 12 inches long, peduncle hairy about 6 inches long. Bracts 4 or 5 green edged with pink glabrous 6 inches long 1 inch wide lanceolate acuminate. Rachis yellow dotted with green ½ inch through. Flowers 14 or more in each bract. Bracteoles long acuminate white. Pedicels long. Sepals and petals lanceolate acute fuscous brown; base of sepal pubescent, above glabrous. Stamens slender, anthers linear. Staminode ovate apiculate fuscous. Fruit pear-shaped bluntly 3 angled, apex truncate, orange ½ inch long, pedicel ½ inch long flattened.

NEW IRELAND.—Introduced by Micholitz (Distrib. number H. B. S. 7274. I thought at first this might be *H. buccinata*, Roxb., of Amboina, but that has much longer branched inflorescences, a hairy rachis, and if Rumph's description of his *Folium buccinatum asperum* is the same thing as Roxburgh states, it has the stems wrinkled and rough like a shark's skin; none of which characters the New Ireland plant possesses.

AMERICAN SPECIES IN CULTIVATION HERE

H. BIHAI, L.—Is commonly cultivated here, and is very conspicuous from its large smooth scarlet bracts and greenish-white flowers. The typical plant is said to be about 18 feet tall, and *H. humilis*, Jacq., much smaller. There does not seem to be any other difference between the two species, and Mr. Baker suggests that *H. humilis* is only a variety of *H. Bihai*. The plant grown commonly in Singapore is about 6 feet tall, and would, therefore, belong to the variety *humilis*.

H. AURANTIACA, Ghesb. (*H. brevispatha*, Hook.).—A dwarf species with rather narrow green leaves and orange-coloured flowers, has long been in cultivation here but seldom flowers. It is a native of Mexico.

H. METALLICA, Planch., *Bot. Jag.*, 5, 315.—A species of Heliconia which has very long been in cultivation here is, I suppose, this plant. The leaves are dark shining green and purple beneath when young, leaves of older plants losing this purple tint. The flowers are borne on a long slender peduncle about 6 feet from the ground, and the rachis is zigzag, the bracts ½ narrow and pale green, the flowers scarlet-crimson with green tips. In the figure given of the plant in the *Botanical Magazine* the rachis is given quite straight and erect and the bracts dark green, otherwise the plant is quite similar. *H. metallica* was introduced from Sierra Nevada, Santha Martha, by Planchon and Linden in 1856.

There are a good many more species of Heliconias in South America which would be welcome additions to our gardens here, if they were procurable. *H. N. Ridley*.

FRUIT REGISTER.

STRAWBERRY LAXTON'S FILLBASKET.

This variety has been grown sufficiently long to test its cropping and other good qualities, but I would direct especial attention to its splendid flavour—an important point with all fruits, and especially with Strawberries. Fillbasket is well named, as it is an excellent cropper. The habit of growth is robust and compact, so that this variety rarely fails even in soils that are by no means the best. It has other good qualities that should not be overlooked, one is its freedom from mildew—at least, such is my experience in the

Sovereign. I recently saw some forced fruits of Fillbasket at Gunnersbury House, Acton, where it is regarded highly as a forcing variety, and as possessing splendid flavour. With regard to size, the fruits, when well grown, are large, and although not soft are very juicy. The fruit is glossy and of a bright scarlet colour. It travels well, and is, therefore, useful in cases where fruits have to be sent by rail. The plants do not need a great space between them, but I would advise planting them in deeply-dug soil. Runners planted early will furnish good fruits next season, and they will continue to furnish heavy crops of fruit for two or three years. *G. Wythes.*

NOTES FROM A "FRENCH" GARDEN.

We have finished planting the last of the Melons, and for a few days to come our principal work will consist of watering, cleansing and examining the plants under the lights and in the open garden.

The Cauliflowers intended to succeed the batch planted amongst the Carrots, which are now marketed, will require an abundant supply of water, for the crop is now in some cases already of a moderate size.

Young plants of Celery, Endive and Cauliflower, which are to be planted out in a few days, require attention, especially in the matter

FIG. 7.—ROSE "THE GARLAND": FLOWERS WHITE, FAWN-COLOURED IN THE BUD.

(Photograph by F. Mason Good.)

northern part of the country as well as in Middlesex. A Strawberry that is almost immune from mildew in a low-lying district is a gain, and, doubtless, in this respect it is greatly aided by the robust leathery leaves. The plant itself has a compact growth, throwing up a great number of flower-spikes. Its period of ripening may be classed as late mid-season. It is valuable as a successional variety, to follow the well-known Royal Sovereign, which was one of the parents of Fillbasket, Laxton's Latest of All being the other parent. Latest of All has a good deal of British Queen in its composition, and is noted for its splendid flavour, so that Fillbasket doubtless gets its Queen-like flavour from Latest of All. Fillbasket grown in pots crops equal to Royal

ROSE "THE GARLAND."

This beautiful old-fashioned climbing Rose is generally regarded as a hybrid between *R. multiflora* and *R. moschata*—the musk Rose. The flowers are produced in immense clusters, and are of a fawn-coloured shade in the bud state, but the older flowers lose this tint and are almost white. The growth is very vigorous, and a plant quickly furnishes a wall or pillar, the flowers hanging in profusion from the long arching shoots. The climbing Roses have lately become so popular in gardens, that it is difficult to believe them to have been so long neglected. It must be remembered that some of the older kinds such as Wallflower, The Garland, &c., are quite as beautiful as the newer kinds, and are much cheaper to purchase.

of watering. We prefer to have the plants of a medium size when transplanting, rather than larger, as at this season large plants wither much when they are disturbed.

The Melons will now require much water and an abundance of ventilation. If the weather remains favourable we shall allow the ventilators to remain open at night-time. The growth of these plants is splendid, the leaves being thick, large, and of a beautiful green colour. The stems are strong in proportion, and the fruits promise well, so that we expect to have a splendid crop. In the case of the plants planted at the end of March, we have allowed a second fruit to develop on each plant in cases where this was possible, and the first fruit on this batch is now at its full size. We cut our first Melon on June 22. Pruning has been rigorously practised, most

of the small shoots have been cut back, but we have not removed very many at one time, for this would unduly weaken the plant.

The Cucumbers planted at the end of April are now in bearing: the ventilators remain open at night-time.

The early batch of Endive has been harvested. The crop has proved fairly good, although some few plants seeded owing to the unsuitability of the ground and a shortage of water. To grow Endive successfully at this season of the year the ground must be well prepared, heavily manured, and frequently watered. We have sown Endive "La Ruffee" and Batavian Green Endive on old manure beds: this will be our last batch of Endive this season. The plants will be afterwards transplanted to an open part of the garden.

Now that all our spring crops have been cleared, we can estimate the results on the whole to have been very satisfactory. The plants have done well, although we have not had the amount of manure we required. The prices obtained for the produce have been well above our expectation. Indeed, the Cos Lettuces and the Passion Lettuces realised double the prices they did in the Paris market this year, but, curiously, the little "Black Gott" was 25 per cent. cheaper. *P. Aquatics, Maryland, Essex. June 23.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

AMERICAN GOOSEBERRY-MILDEW.—As an appendix to the Board of Agriculture's instructions regarding the treatment of Gooseberry bushes infected with mildew, it may be pointed out that it is the easiest matter possible to destroy single bushes. And in this way: Saturate one or more newspapers in paraffin oil and dispose them in good-sized pieces about the bush to be destroyed, ignite one piece and in a few minutes the bush will be so far consumed that its own life, and that of any parasite attached to it, will be extinguished. A less rapid method would consist in severing the stem just above the ground, but I know from trial that the firing with paraffin is absolutely effective. *B.*

EFFECTS OF LOW TEMPERATURE IN S.E. SCOTLAND.—Sir Herbert Maxwell, having lately published in these pages a note on the effects of the April frost on the south-west coast of Scotland, it may be of interest to put on record the results of the same low temperature on the south-east of Scotland. The elevation is 100 feet above the sea level. The sea is distant about three miles east as the crow flies. The temperature, as registered at the meteorological station kept here, was:—

Date.	Ground thermometer.	Protected thermometer 4 feet from ground.
April 23 14°	(18° of frost)	27° (5° of frost)
April 24 22°	(10° of frost)	31° (6° of frost)
April 25 12°	(20° of frost)	19° (13° of frost)

The following are some of the many plants grown here, not an exhaustive list, but sufficient to show the general effects of the low temperature.—*Injured*.—Euonymus, various (shoots killed back), Aucubas, various (badly damaged), Hypericum patulum and others (slightly browned), Cneorum tricoccum (some branches killed), Pittosporum Mayi (shed most of its leaves), Abies Morinda (tips browned), Liquidambar styraciflua, Griselinia litoralis, Escallonia macraetana (some), Cotoneaster angustifolia (young plants), Aralia, Sieboldii (killed), Gunnera scabra, Camellias (leaves browned and mostly shed), Aciphylla Lyallii and A. squarrosa (slightly injured), A. Munroii (badly injured), Rhododendrons (leaves of a few touched), Buddleia variabilis, B. Veitchii, B. Colvitei (wilt), B. Hemslayana, various (in open tips killed, on walls untouched), Jasminum primulinum (tips killed, wall), Stauntonia hexaphylla (thick cut, wall), Solanum jasminoides (wall), Phytolacca japonica (wall), Laurus Benzoin (shoots cut back) Enkianthus japonicus (bamboos (where exposed, browned), Cercidophyllum japonicum

(all young shoots killed), Nuttallia cerasiformis (ditto), Veronicas (in the thick-leaved, New Zealand species). In cases where no details are given the damage was slight. *Untouched (on walls)*.—Rosa levigata, R. Banksia, R. bracteata, Abelia rupestris, Carpentaria californica, Jasminum grandiflorum, Ceanothus Gloire de Versailles, C. dentatus, C. divaricatus, Ceanothus punicus, Solanum jasminoides, S. crispum, Schizophragma hydrangeoides, Escallonia Langleyensis, Coronilla Emerus, Halimodendron. *In the open*.—Coronilla Emerus, Azara microphylla, Olearias various, Eremata, Gerbera Jamesonii. Among herbaceous and rock plants practically no damage was done, the drier climate here probably saved many plants that suffered on the west coast. *Archibald Euchen-Hefburn.*

NEW MELONS AND THE R.H.S.—Recent notes on this subject having appeared in your pages, and seeing that the busy showing seasons is at hand, I think your readers, who may be prospective exhibitors, should understand the requirements of the council of the R.H.S. Last year, at the fortnightly meeting immediately preceding the great fruit show, I decided to place two Melons, one a scarlet-fleshed and the other a white-fleshed variety, before the Fruit Committee for an award. I think I am right in saying that an "A.M." was awarded in each case, and in one case it was practically unanimous. I went to the meeting during the afternoon, and, with a not unnatural desire to see how the fruits had fared, I tried to find them or their remains. All I could find, however, was one empty plate with the usual card with exhibitor's name, &c., and on another plate a very small portion of the scarlet-fleshed fruit and a very few seeds, also the exhibitor's card. I waited until quite late in the afternoon, but found that no visible trace of the committee's recommendation appeared, so that any visitor curious to know would go away with the idea that the exhibits had been unworthy of any notice. Next morning I received from the secretary a letter as below:—

"Dear Sir,—At the sitting of the Fruit Committee to-day an Award of Merit was proposed for a Melon sent by you, and the committee recommend the council to award it. The council wish me to explain to you that they cannot act on the recommendation of the committee, as they had already resolved that awards should only be given to Melons after they had been tried at Wisley. They hope, however, that you will send seed to Wisley, so that the resulting fruits may be found such as to enable them to give you the award next year.—Faithfully yours, "W. WILKS."

By Order of the Council.
I am still in doubt as to which of the Melons I was desired to send seed of to Wisley, for, as will be seen by the above letter, no information was given to guide me. One is bound to ask why the Society calls together in committee the best experts it can find, and then ignores the recommendations. Again, if the council made such a resolution, it should have been published in the "Arrangements for the Year," or it should not be brought into force until another year had commenced. This would have been an act of grace that might have taken away the sting of the action, though, I think, with others, that such a resolution is unwise, on the fact of it, if committees are necessary. I see that this year, Melons are included in the subjects that it will be necessary to send to Wisley for trial after having been submitted to committee at Vincent Square, but the rule is rendered indefinite by the addition of the words "and similar subjects." Last year the council apparently thought that Melons could be classed with Cucumbers. Before writing this protest, I had hoped to see the report in the society's *Journal* of the transactions at the meeting of which I write, but probably this would have been too late to be of service this year, as I see that the most recent issue of the *Journal* only brings us down to June, 1907, and I shall, evidently, have to wait another season before I learn officially which, of the two Melons submitted, the council wished me to send seeds of to Wisley. *J. C. Tallack, F.R.H.S.*

PROSPECTS OF THE ROSE SEASON.—The weather which our Roses experienced in April, when they were beginning to grow, was not by any means favourable to their successful develop-

ment. On one memorable evening we had in south-western Scotland 20° of frost. While in my own garden the older and stronger varieties withstood this adverse experience nobly, and in many instances seem little the worse, Roses of recent origin and of somewhat more delicate nature, have, with a few notable exceptions, achieved almost nothing in the flowering direction. At the present moment the most promising among the newer varieties are Isabelle Milner and Mrs. Dudley Cross; W. E. Lippiat, a native of New-towards; Iliawatia, a "gent of purest" ray serene; and the finely-foliaged and splendidly-flowered Lady Gay. Of the older varieties, those on which I chiefly rely this season are Captain Hayward, a beautiful and fragrant Rose that never fails to succeed; A. K. Williams, whose first flower-buds are frequently hard and abortive, but in autumn quite reliable; Horace Vernet, one of the finest of the dark crimson hybrid perpetuals; Margaret Dickson, Frau Karl Druschki (the grandest Rose of the last decade); Hugh Dickson and J. B. Clark (Irish rivals in renown though the former is much the finer Rose); Warrior, with lovely chocolate-coloured foliage, and blood-red flower-buds; Papa Gontier and Gloire Lyonnaise. *David R. Williamson.*

THE FLOWERS OF SPENSER.—It is a great pleasure to find Canon Flacombe continuing his studies in plant lore, and, if one may be permitted to make a remark, it is that the gifted author may not carry the compression of his notes too far. In his allusions to flowers, Spenser is undoubtedly the most difficult of all our poets to understand, and he never hesitated to coin a name to suit himself. One such is *Astrophel*, which Canon Flacombe, following Nares conjecturally, refers to *Aster Tripolium*. *Astrophel* was a pet name of Sir Philip Sydney, and the name of a plant designation was first employed in connection with that Mirror of Courtesy. Its flowers were red, fading to blue, and had a "dew" filed star in the centre of each, so that another plant than the wild *Aster* must have been in the poet's mind. Then Canon Flacombe must have overlooked several authorities, for the early cultivation of *Amaranthus* in English gardens—Turner, Hill, Mountain, Tassier, Lyte, Heresbach, all mention it, its English names being Flower gem, Flower amour, and Purple Velvet-flower, which Aiton, and subsequently Mr. Britten, has identified with *Amaranthus tricolor*. No doubt Spenser would be well acquainted with it as a garden flower in the many gardens of which he would have the entry—Lord Gray's, at Wilton, Earl Essex's, in London, and that of the Sydneys. *R. P. Brotherton.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

JUNE 23—Present: Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair); Dr. A. Voelcker, Rev. W. Wilks, Sir J. T. D. Llewellyn, Messrs. E. M. Holmes, G. Gordon, H. T. Gussow, G. S. Saunders, J. H. Curtis, W. C. Worsdell, G. Maseley, J. E. Bennett, P. G. and J. C. Holden (secretary). Visitors: Prof. Hansen, of Dakota, U.S.A., and Mr. Scrase Dickens.

Cherries eaten.—It was reported that the holes in the fruits of Cherry which were received from Sir Robert Harvey at the last meeting were due to the feeding of the larvae of the winter moth.

Malformed Odontoglossum.—Mr. WORSSELL reported that one of the flowers of *Odontoglossum crispum* received from G. Wilson, Esq., F.R.H.S., of Haywards Heath, had the three stamens of the normal whorl all developed, instead of only one as is usual. The second flower had a normal column and normal sepals, but each of the three petals had become partly modified into stamens and bore anthers.

Dodder. Mr. H. T. GESSOW showed photographs of *Oscutia trifolia* attacking Clover and Kohl-rabi, and of *C. chilensis* growing upon Lucerne, Kohl-rabi, Rye grass, and red and white Clover. Dr. VOELCKER said that experiments had been tried with Chilian Clover seed containing Dodder, and it had been found that though the Dodder had germinated and grown

upon the Clover in the first year, in the second none had been found, as it had failed to form seed. Mr. Gussow, however, thought that seed was, at least under certain circumstances, produced.

Ely hybrids.—Mr. SCRASE DICKINS showed seedlings of *L. croceum* × *L. elegans* and *L. van Houttei*. The plants showed extraordinary vigour, which the raiser attributed partly to the fact that they were seedlings, and partly to their hybrid origin. The hybrids do not set seed when pollinated with one another's pollen, but set seed freely when pollinated with pollen from *L. elegans*. The forms varied considerably among themselves, and forms of *L. taburicum* could be well matched among them. The *L. elegans* parentage was evident in many by the reflexing of the perianth pieces. Unfortunately the hybrids are not disease resisting. A hearty vote of thanks was accorded to Mr. DICKINS.

Effect of ammonium salts on flora.—Dr. VOELCKER showed a Fern which had developed under curious circumstances. A series of drain pipes were filled with soil and each was covered at the base with a perforated slate, below which a glass funnel had been fixed in order to catch the drainage water. Through some a solution of ammonium sulphate had been passed, through others ammonium chloride, others nitrate of soda, and others were only afforded distilled water. The Ferns had grown through the perforation of the slate into the tunnel, only in those cases where ammonium salts had been passed through the soil. This was apparently due to a difference in the reaction of the soil in the different cases.

Phlox leaves malformed.—Mr. WORDSELL drew attention to the peculiar form at times assumed by the leaves of *Phlox*. Sometimes the leaves appeared as ascidia, or as pockets, or merely as wings on the midrib. This condition, Mr. MASSEE pointed out, was due to the presence of the eelworm *Tylenchus devastatrix*, large numbers of which were present in the plants. This and other species of eelworm were responsible for many malformations in plants, as is seen in the Tulip-rooted Oat, the thickened neck of the Onion, malformed flowers in cereals and various wild grasses in one of *Agrilus* vulgaris, a malformation due to an eelworm has been taken as a character upon which to found a variety, and warts and knobs upon roots.

Arisema contangueinum.—Mr. MASSEE, on behalf of Mr. H. J. ELWES, showed plants of this new species.

Plant breeding.—Prof. HANSEN, of N. Dakota, who is passing through London on his way to Russia and Siberia on his fourth journey of exploration, received a hearty welcome from the committee. In the course of his remarks he alluded to the efforts which were being made to obtain fruit trees which would maintain their existence without coddling through the rigours of the American winter, and remarked upon the great measure of success which had already attended their efforts to obtain frost-resistant Plums, Raspberries, &c.

Fruits of Lathraea clandestina.—Mr. BOWLES showed capsules of this interesting and beautiful parasite to illustrate the explosive mechanism by which the seeds are flung out of the capsule when ripe. The two valves of the capsule suddenly roll inwards and fling the seeds out a very considerable distance.

Primula angustidonta.—From Messrs. VEITCH, of Chelsea, came a pan of this beautiful *Primula*, which is closely allied to *P. Poissonii*, and bears several whorls of drooping, deep, clear purple flowers upon its rigid erect stems.

Miltonia vexillaria.—Baron SCHROEDER, V.M.H., sent a spike of *Miltonia vexillaria* with normal flowers, and another with partially double flowers, which was borne upon a plant divided from the former a few years ago. The parent had always (for over 20 years) borne normal flowers, while each year since its separation the offspring had produced semi-double flowers.

The Sweet Pea "Zephyrus."—From Mrs. R. H. BROWN, of The Gables, Histon, came flowers of a Pea raised by crossing *Zoe* (a medium blue) with a Countess Spencer (Paradise) in 1905. Mrs. Brown had obtained the same thing from a number of crosses made subsequently between flowers of a deep blue and others of a pink colour, in addition to others, of all shades of blue and of the "Spencer" form.

Cadmyra Peas.—Mr. A. W. STOTT showed the offspring of a Pea occurring spontaneously in Palestine, 12 miles from Jaffa, four years ago. Many hybrids have been raised from crosses between this wild form and the best of the cultivated ones, and in some the coloured flower is reproduced, in others the flowers are white; in some the serrated edges of the foliage, normal in the wild plant, are retained, but in others the margin of the leaf is practically entire.

RICHMOND HORTICULTURAL.

JUNE 24.—The 34th annual exhibition of the above Society was held in the Old Deer Park, Richmond, on this date. In the extent and variety of the exhibits, it was one of the largest and finest shows ever held by the Society, the members of which embrace Richmond, Twickenham, Isleworth, Mortlake, East Sheen, Ham, Barnes, and Roehampton. The weather was gloriously fine, and the visitors attended in great numbers. Roses were, as usual, extensively shown by the trade growers, as well as by local gardeners, and they contributed immensely to the attractions of the exhibition, the blooms being more than usually fine in all sections. Displays of hardy flowers, tuberous-rooted Begonias, Carnations, Streptocarpus, Gloxinias, and hardy perennials from members of the trade were particularly noticeable.

GROUPS ARRANGED FOR EFFECT.

These groups were not to exceed 100 square feet. The 1st prize was awarded to Sir C. SWINLEN LANE, Otland Lodge, Weybridge (gr. Mr. L. Locky, who had a very gay group, without, however, possessing any decided feature, if we except three strong well-flowered plants of *Lilium auratum*. 2nd, Mr. W. VAUSE, nursemyn, Leamington, Warwickshire, who put up a group with simpler materials than the foregoing, but it was lacking in plants required to break the level monotony of the surface. *Codiums* (Trottons) were freely used, but the colours of these plants suffered from the proximity of white-leaved *Abutilons*.

In the class for a smaller group measuring 60 square feet, the 1st prize was awarded to Lady WAECHTER, Terrace House, Richmond Hill (gr. Mr. H. Bartoott). In this group the main idea was to contrast the red colours of *Hippeastrums*, Carnations, Miss Willmott Verbena and *Celosia pyramidalis* with the white of *Lily bulbs* and of *Caladium foliage*. 2nd, C. M. BARTLETT, Esq., Uplands, East Sheen (gr. Mr. Hicks). This group consisted of *Caladiums*, *Dracenas*, *Codiums*, &c., arranged on a groundwork of *Adiantum Ferns*, with plants of *Cerodendron toxiifolium* and white-flowered *Lilies* as solitary plants, and an edging of *Caladium Wightii* and *Panicum variegatum*.

The winners in the class for six Palms were: 1st, Mr. W. VAUSE; 2nd, Lady WAECHTER.

Roses.—Cut blooms of great excellence were shown in triplets in the class for 48 varieties, distinct. Messrs. D. PRIOR & SON, Colchester, won the 1st prize; Messrs. R. HARKNESS & Co., Bedale and Hitchin, the 2nd prize; and Messrs. FRANK KELLER, Hill, Colchester, the 3rd prize. There were five competitors in this class.

In the class for 24 Roses, distinct, three blooms of each, the winners were: Messrs. B. R. CANT & SONS, 1st; G. & W. H. BURCH, nursemyn, Peterborough, 2nd; and Messrs. D. PRIOR & SON, Colchester, 3rd. There were six competitors for 12 Roses of distinct varieties, arranged in triplets. The 1st prize winners were Messrs. HARKNESS; 2nd, Messrs. D. PRIOR & SON.

A class for 24 Roses, distinct, single blooms, open to amateur growers only, resulted in E. J. HOLLAND, Esq., Silverdale, Sutton, Surrey, taking the premier honour with a beautiful lot of blooms, the finer of which were Helen Keller, J. B. Clark, Florence Pemberton, Mrs. J. Laing, Her Majesty, and Gustave Pigneau. 2nd, Rev. J. PEMBERTON, Havering-atte-Bower. In the finest condition we may specify Etienne Levet, Helen Keller, Her Majesty, J. B. Clark, J. B. Clark, 3rd, W. LEGGETT, Esq., Maldon Road, Colchester. In the above class competition was keen. For 12 blooms, distinct, E. J. HOLLAND, of Silverdale, Sutton, was the winner of the 1st prize, and his blooms of J. B. Clark, Mme. Jules Graveraux, Bessie Brown, Mrs. J. Laing, W. Shean, and Victor Hugo were very fine.

2nd, Rev. J. PEMBERTON, with very fine blooms of Caroline Testout, J. B. Clark, Florence Pemberton, and Dean Hole, 3rd, W. C. ROMARNE, Esq. Special prizes were given by Lady RUGGERIE for 12 H.T. Roses of distinct varieties. Messrs. HARKNESS & Co., Hitchin, were 1st with Dean Hole, Mildred Grant, Alice Lindsell, J. B. Clark, and Lady Ashdown as their best blooms. 2nd, Mr. J. BROWN, Peterborough, with fine examples of Bessie Brown, Queen of Spain, Caroline Testout, &c.

Garden Roses formed a class apart; the 1st prize in this section was awarded to an extensive exhibit from the gardens of L. WARDLE, Esq., Petersham House.

Sweet Peas formed a lovely feature of the show, there being many exhibitors of this flower. The winner of the 1st prize was the Earl of DYSART, Ham House (gr. Mr. T. F. Conway). We remarked the fine varieties Frank Dolby (light blue), Mrs. Hardcastle Sykes (pink), G. Herbert (crimson), Vera Jeffrey (light rose), King Edward VII. (deep crimson), St. George (orange and scarlet), &c. 2nd, Mr. W. H. ONLEY, Petersham Vicarage (gr. Mr. Gower); 3rd, E. MOCATT, Esq., Woburn Place, Addlestone (gr. Mr. Stevenson).

Sweet Peas in bunches were shown for Mr. Sydenham's special prizes, a competition in which Lord DYSART's gardener took the 1st prize.

MISCELLANEOUS PLANTS.—*Aspidistras* and Ferns formed a pleasing change from the exhibits of flowers; good plants of the former came from Mr. E. G. CATTLEY, 94, Sheen Road.

Begonias made a bright show, the 1st prize for twelve of these plants being won by W. J. LEWARS, Esq., Bellari, Sidcup (gr. Mr. Rabbitt). The flowers were large and of double-flowered varieties.

A few plants of *Streptocarpus* were shown. G. ATKINS, Esq., East Sheen (gr. Mr. J. Hill) was given the 1st prize for these flowers, and Lady WAECHTER the 2nd prize. Mr. Hill also took a special 1st prize for *Begonias*.

Caladiums of moderate sizes were seen in a class for six plants, the 1st prize being awarded to Mr. J. HUTT, gardener at Manaton.

Table decorations formed an extensive feature, and showed a great improvement on the arrangement of past years. The prizes were open to lady exhibitors in or out of the Society's district, and the 1st fell to Miss N. H. COLE, The Vineyard, Feltham, for a decoration consisting of white and pink-flowered Carnations, Grasses, *Gypsophila* and *Asparagus plumosus*; Miss C. B. COLE secured the 3rd prize with yellow English Iris, *Doronicum* and *Asparagus*, &c. This last-named exhibitor took the 1st prize for a device consisting of three vases suitable as a dinner-table decoration.

A good-sized group of Orchids was contributed by H. LITTLE, Esq., Baronsholt, Twickenham (gr. Mr. A. Howard). A 1st prize was awarded to Cattleya Mendini Princess Ida, white with a faint tinge of mauve, and a purplish labellum.

VEGETABLES AND COTTAGERS' EXHIBITS.

Some very superior vegetables and roots were shown in the two competitions for Messrs. Sutton & Sons', Messrs. Webb's and Messrs. Jas. Carter & Co.'s prizes for vegetables; and the cottagers' exhibits were beyond all praise.

Fruit.—Some excellent Grapes were shown by Sir H. GREENWELL, Marden Park, Caterham (gr. Mr. Lintott), who was 1st for three bunches of Foster's seedling variety; 2nd, Mr. CARTER, and Mr. G. WESTON, gr. Eastwell Park, Ashford, Kent. 3rd, Black Hamburg Grapes were very good, the bunches massive and large. Mr. WESTON was 1st for three bunches, and Mr. LINTOTT 2nd with heavily-shouldered and large-berried examples.

Collection of six dishes of fruit.—The 1st prize in this class consisted, besides money, of Lady Waechter's Challenge cup. This prize was won by Mr. J. LOCK, Otlands Lodge Gardens. He showed Foster's Seedling and Macintosh Court Grapes, all capital specimens; Dryden Nectarine, Duke of York Peaches of extraordinary size for this variety; Hero of Lockinge Melon, and Black Bigarreau Cherries; 2nd, Mr. T. F. CONWAY; his exhibit consisting of Webb's Epicure Melon, Foster's Seedling and Black Hamburg Grapes, Brown Turkey Figs, Early Rivers Nectarine, and a dish of Peas-bes, unnamed.

NON-COMPETITIVE EXHIBITS.

These were numerous and meritorious. Messrs. J. VEITCH & SONS, LTD., King's Road, Chelsea, made an extensive show of Roses in pots, including Rambler varieties of large dimensions, and some *Lilium auratum* in fine flower. From Messrs. CUTBUSH & SON, Highgate and Barnet, came a number of Carnations, *Mitrosideros floribunda*, Queen Alexandra Spiræas, Polyantha Rose Mrs. W. H. Cutbush, *Colours cordelia*, Begonias, &c. (Silver-Gilt Medal.) Messrs. PEEB & SONS, of Morden and West Norwood, made a display of hardy herbaceous cut flowers, viz., Delphiniums of their raising, Carnations, the rare *Centaurea dealbata* and *Baptisia australis*, with striking dark blue flowers; *Iris spuria* in variety, and a few Roses. Messrs. THOS. WARE & CO., Feltham, set up a large table of cut blooms of hardy herbaceous plants in great variety. Mr. W. THOMPSON, Sheen Nurseries, was awarded a Gold Medal for a large group of foliage and flowering plants that occupied the middle area of one of the large marquees. Mr. AVOS PERRY, Nurseryman, Enfield, showed, in his usual pretty style, Water Lilies, likewise Delphiniums, *Linaria dalmatica*, varieties of *Lilium*, &c. (Gold Medal.) Mr. RUSSELL, The Richmond Nurseries, Richmond, showed the new pink Spiræas, the new *Hedera dentata variegata*, a striking variety, with large, white-blotched leaves. He also filled a large cart with hardy shrubs and climbing plants, many of which had variegated foliage.

HORTICULTURAL SHOW AT THE FRANCO-BRITISH EXHIBITION.

(Continued from page 422.)

JUNE 24, 25, 26.—In our last issue, owing to exigencies of time and space, we were only enabled to refer briefly to this flower show. The Palace of Music, in which the exhibits were displayed, is a fine, well-lighted building, but it was oppressively close, and many flowers, especially Roses, flagged in the dry, hot atmosphere. Some of the exhibits were accommodated around the walls of the building outside, where the large eaves of the roof form a covered way.

The absence of French exhibitors was disappointing, for if we except the group of Orchids shown by MM. MARON ET FILS, Brunoy, the exhibits of FRENCH ROSES were insignificant. There was a collection of Strawberries from Messrs. MILET & SON, Bourg-la-Reine, near Paris, and, even when allowance is made for the distance they had travelled, they must be regarded as far below our standard of quality in this fruit. The presence of sulphur on the berries did not enhance their appearance. Some were not much larger than hazel nuts; there were white kinds, others long and narrow, and some almost divided in two by a deep suture. A collection of Nymphaeas from Mons. LAGRANGE, Paris, would have proved interesting had the flowers opened.

When we turn to the British exhibits, something better may be said; indeed, there were one or two distinct features of merit. We may enumerate a magnificent group of Carnations numbering 290 plants, all of the highest standard of quality, shown by Messrs. H. CANNELL & SONS, Swanley Kent; excellent exhibits of Ferns shown by Messrs. J. HILL & SON, Lower Edmonton, and Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, respectively; pot fruit trees from Messrs. GEO. BUNYARD & CO., LTD., Maidstone, and Messrs. T. RIVERS & SONS, Sawbridgegworth; a noteworthy group of Orchids from the gardens of SIR JEREMIAH COLEMAN, Bart., Park, Reigate (gr. Mr. W. P. Bound); and, in an admirable collection of tuberous-rooting Begonias generally, shown by Messrs. T. S. WARE, LTD., Feltham, a superb specimen of the delicate pink-coloured variety named after Lady Cromer. The plant bore several magnificent blooms, the finest of which measured 10 by 8 inches; it is of the *Camellia* type of flower; the pink in the petals shades to white on the margins. This was the finest individual plant in the show. The schedule made provision for many competitive classes, but the majority of the exhibits were either honorary or trade displays. The jury was composed of seven English and a like number of French horticulturists, the president

being Colonel D. Prain, C.I.E., with Mons. Viger, vice-president.

COMPETITIVE CLASSES.

In the class for a group of plants in or out of bloom, to occupy a space measuring 20 feet by 8 feet, the 1st prize was awarded to Messrs. CANNELL & SONS for their exhibit of Carnans.

Lord HOWARD DE WALDEN, Audley End, Saffron Walden (gr. Mr. James Vert), showed the best group of ornamental foliage plants and Ferns in an exhibit of *Codiaeum* (Crotons), *Polka*, pleasingly arranged with *Cocos Palms*, Ferns, &c., the group being awarded the 1st prize; and the 2nd prize falling to Messrs. JOHN LAING & SONS, Forest Hill.

The best exhibit of Orchids in a class for a group of these plants was shown by Messrs. ARMSTRONG & BROWN, Tuabridge Wells, who had choice and rare examples, pleasingly displayed, the centre being elevated in the form of a mound. Amongst their finer subjects was a fine pan of *Cypripedium bellatulum*, containing 10 blooms; also *C. Godetoyae leucocheilum*, *C. callosum* Sanderae, a fine spike of *Cologyne pandurata*, and another of *Cattleya gigas*. We also noticed an excellent plant of *Cypripedium glaucophyllum*, *Odontoglossum percutum* in fine form, *O. Adrianae* and *Laelio-Cattleya Blechlyensis* Orchidhurst variety. The 2nd prize was awarded to MM. MARON ET FILS, Brunoy, for a display consisting principally of showy *Cattleyas* and *Laelio-Cattleyas*.

Mr. GEO. MOUNT, Canterbury, met with no competition in the class for Roses in pots, and he was awarded the 1st prize of a Gold Medal.

There was a class for 36 blooms of Roses, and the Gold, Silver-Gilt, and Silver Medals offered were won by Messrs. G. & H. BURCH, Peterborough; Messrs. D. PRIOR & SON, Colchester; and Mr. G. MOUNT, Canterbury, in the same order as their names. On the second day the Roses were so drooping as to be almost unrecognisable. Several other classes were allotted to Roses.

The fruit classes were poorly contested, and call for no special comment, save that some finely coloured Nectarines with remarkably strong growths—the fruits in most cases being attached to the shoots—came from MONS. OMER-DÉCAGIS, Rue Pierre Lescot, Paris.

In the vegetable classes Mr. Edwin Beckett, gardener to Hon. VICARY GIBBS, Aldenham House, Elstree, and Mr. Searle (gr. to the Marquis of NORTHAMPTON) had things all their own way, for although the SOCIÉTÉ DES MARAÎCHERS DE LA RÉGION PARISIENNE were placed higher than Mr. Beckett in one class, viz., for a collection in 18 distinct kinds, it was evident that this was done as a compliment.

NON-COMPETITIVE EXHIBITS.

The group of Orchids shown by SIR JEREMIAH COLEMAN, Bart. (gr. Mr. W. P. Bound), attracted great attention from its visitors, the majority of the sightseers being unused to flower shows, but who had read of the wonders of the Orchids and insectivorous plants in the lay Press. Although they did not find all they expected, there was a rich display of such fine things as *Laelio-Cattleya Epicastro*, Gatton Park variety, a many-flowered spike of *Oncidium macranthum*, *Spathoglossum Colmanii*, *Epidendrum prismatocarpum*, *Barkeria spectabilis*, *Masdevallia Harryana* Gatton Park variety, *Odontoglossum Phoebe splendens*, *Cirrhopetalum pulchrum*, *Brasso-Cattleya Mary*, *Lissocichlus giganteus*, &c.

The group of Ferns shown by Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, showed to advantage on the platform. There were 150 specimens in all, most of them large plants. *Nephrolepis superbissima* and a finely-coloured batch of *Adiantum farleyense* attracted our special attention. On the opposite corner Messrs. J. HILL & SON, Edmonton, showed an equally effective group of Ferns, mostly specimen plants in big pots. They showed among others, well-coloured plants of *Adiantum Veitchianum*, *Gleichenias* in variety, *Asplenium nidus* (the Bird's Nest Fern), *Davallia retusa*, *Poly-podium lepidopteris sepultum*, *Nephrolepis amabilis*, *N. ameripohii*, &c.

In Messrs. GEO. BUNYARD & CO.'S exhibit of pot fruit trees were excellent Cherries of the Govern-

ment Wood, Elton Heart, and Bigarreau Napoleon varieties. Also Figs, Peaches, Strawberries, &c.

Messrs. T. RIVERS & SON, Sawbridgegworth, had also fruit trees in pots, their samples of Bigarreau de Schreken Cherry being very fine; and a tree of Dryden Nectarine was laden with fruit;

A group that especially appealed to us as being well arranged was Messrs. ED. WEBB & SONS' exhibit of vegetables and Melons, for which a Gold Medal was awarded.

Well-grown Caladiums were staged by Mr. RICHARD HOFFMAN, Tower House, Streatham. Messrs. J. PEED & SON, Ruppell Park, had a collection of Gloxinias. Sweet Peas were very freely staged; we noticed groups of these flowers from Messrs. DOBBIE & CO., Rothsay. This firm had many novelties, including the new reddish-orange variety *The King*. Some beautiful varieties of Spanish Irises and many kinds of *Flemings* were also shown by Messrs. DOBBIE. Other exhibitors of Sweet Peas were Miss HEMES, Holdfast Hall, Upton-on-Severn; Mr. C. W. BREADMORE; Messrs. JARMAN & CO., Chard; Messrs. G. & A. CLARK, LTD., Dover, who had in addition an assortment of garden flowers; Messrs. E. W. KING & CO., Coggeshall; Mr. W. J. UNWIN, Histon, Cambridge; and Messrs. CARTER, PAGE & CO., London Wall.

Exhibits of Roses were displayed by Mr. GEO. MOUNT, Canterbury, Mr. JOHN BARROW, Oadby, Leicester; Messrs. R. H. BATH, LTD., who also had a fine group of Carnations; Messrs. GEO. JACKMAN & CO., Chard; and Mon. HENRI KAZKA, 8, Rue Saint Martin, Paris. The

VICARY GIBBS, Aldenham, contributed sprays of ornamental trees and shrubs from the rich collection at Aldenham House Gardens. Some well-grown Begonias were staged by Messrs. JOHN LAING & SONS, Forest Hill, London. Messrs. BARR & SONS, King Street, Covent Garden, had a number of dwarfed trees in quaint receptacles. Messrs. SUTTON & SONS, Reading, showed varieties of Potatoes of their raising. Well-grown bunches of Grapes were shown by Mr. J. G. WESTON, Eastwell Park, Gardens, Kent, the varieties being Gros Maroc, Black Hamboro', and Muscat of Alexandria. Messrs. FROWLE & SON, Chiswick, had two fine groups of Japanese Maples; Mr. MORTIMER, Kewledge, Farnham, Surrey, displayed very large Cucumbers, some in the seeding stage; also a fine batch of Carnations. Other exhibits of Carnations were presented by Mr. C. F. WALKER, Balcombe; Mr. W. H. PAGE, Tanglely Nurseries, Hampton; and Mons. PAGE, 85, Rue des Bois, Rueil.

Exhibitors of hardy flowers included Messrs. R. WALLACE & CO., Colchester; Messrs. J. CHEAL & SONS, Crawley; Messrs. GEO. JACKMAN & CO., Chard; Messrs. KELWAY & SON, Langport, Somerset; the Misses E. & M. KIPPING, Hutton; Messrs. PATEL & SON, Cheshunt; Messrs. GEO. BUNYARD & CO., LTD., Maidstone; Messrs. BARR & SONS, King Street, Covent Garden; and Messrs. T. S. WARE, LTD., Feltham.

AWARDS.

GOLD MEDALS were awarded to Messrs. Hugh Low & Co., H. Cannell & Sons, Lord Howard de Walden, Armstrong & Brown, George Mount, T. S. Ware, Ltd., G. & A. Clark, Ltd., G. & H. Burch, Hon. Vicary Gibbs, H. B. May & Sons, Dobbies, Ltd., Geo. Bunyard & Co., Ltd., J. Hill & Son, T. Rivers & Son, Millet et Fils, E. Webb & Sons, W. Frowle & Sons, Mons. Debré, and Sir Jeremiah Coleman, Bart.

SILVER-GILT MEDALS to M. Truffaut, Messrs. John Laing & Sons, M. Maron, G. Bunyard & Co., Ltd., D. Prior & Son, Société des Maraichers, Marquis of Northampton, R. H. Bath, Ltd., W. H. Page, C. F. Walker, G. & A. Clark, Ltd., Mortimer, J. Cheal & Sons, G. Jackman & Sons, Barr & Sons, Paul & Son, R. Wallace & Co., G. Anderson, C. W. Breadmore, W. W. King & Co., and Mons. Omer-Décais.

SILVER MEDALS to Messrs. S. Bide & Sons, T. Rivers & Son, M. Campant, A. Edwards, R. Hoffman, Misses Kipping, J. Williams, Hon. Vicary Gibbs, G. Mount, Carter, Page & Co., J. Peed & Sons, G. Jackman & Sons, Miss Hemas, A. J. Harwood, Kelway & Son, John Barrow, Government of South Australia, Jarmann & Co., M. Lagrange, Sutton & Sons, T. Sharpe, M. Page, M. Henri Kazka, M. Pierre Ducher, and F. W. Unwin.

HORTICULTURAL CLUB.

JUNE 23.—On this date, at the Hotel Windsor, the Horticultural Club held the final monthly dinner of the season under the presidency of Sir John Llewellyn, Bart. Subsequently to the dinner, Mr. H. Hitchcock, of Victoria, Australia, gave an address rather than a lecture with reference to "The Development of Gardening in Victoria, Australia, During Recent Years," in which he endeavoured to bring home to his hearers some idea of the variation of climate which is found in the vast area of Australia, ranging from temperate to mid-tropic, and from "thousands of miles" of Fern gullies under the most favourable conditions of shade and humidity to arid deserts. Challenged as regards "thousands of miles" in this connection, Mr. Hitchcock adhered to the statement and justified it fully by explaining that these "gullies" or deeply-cut ravines of valleys consisted of innumerable forks and branches following the drainage of the waterfalls involved, and in these gullies there were all but impenetrable forests of 50-foot tree Ferns and other Ferns and mosses and allied growths, so that if one progressed half a mile in an hour through the tangled wilderness of beautiful frondage he was fortunate. The Australian gardeners are very keen on acquiring new things from the Old Country, but their experience sometimes was disappointing, the acquisitions not adapting themselves to the climate, or, as the lecturer suggested, they were exterminated by the floral judges here. It was thought that awards should be held over for a year with some classes of flower. In the subsequent discussion this point was argued by some members of the Floral Committee present, who explained what pains were taken in this direction by relegating to Wisley for trial many plants which were subsequently judged *in situ* by the visiting committees, while, as regarded reputed novelties, comparison with other similar plants was frequently insisted upon, before an award was given. The size of Australia was somewhat vividly brought to mind by the fact that a single land proprietor, Mr. J. Redman, owns forty-one million acres of land. In the discussion which followed the paper, and in which Sir J. Llewellyn, and M. M. Wilhelm Miller, Chas. Pearson, C. T. Drury, Rev. J. Jacob, Geo. Burnard and George Munro took part, Mr. Miller, editor of the *Garden Magazine* and horticultural editor of *Country Life* in America, alluded to the spoiling of the American climate, or, rather, as he put it, the five American climates, by the constant denudation of forest land.

CROYDON AND DISTRICT HORTICULTURAL.

JUNE 24.—On this date about 50 of the members of the Society paid a visit to the nurseries of Mr. C. F. Bause, Portland Road, South Norwood. Stove and temperate house plants are cultivated here solely, Mr. Bause growing for the trade only. Mr. Luther conducted the party through the glasshouses.

WINDSOR, ETON, AND DISTRICT ROSE.

JUNE 27.—The seventeenth exhibition was held on this date on The Slopes in the grounds of Windsor Castle, the weather being beautifully fine. The exhibits occupied five large marquees, and the exhibition was regarded as the finest held at Windsor. The King's Silver Challenge Cup, which was offered for the best collection of 48 single trusses of distinct varieties of Roses, was again won by Messrs. D. PRIOR & SONS, Colchester. Mr. E. B. LINSELL, Hitchin, won the Cup offered for 18 distinct trusses of Roses in the amateur classes.

BRITISH GARDENERS' ASSOCIATION.

The members of the London branch will assemble at the Main Gate, Kew Gardens, on July 4, at 4 p.m., whence the party will proceed to inspect the gardens.

As a large number of gardeners are expected, it will be necessary to divide the party into sections. Several well-known horticulturalists have consented to act as guides.

All professional gardeners are invited to these outings.

IPSWICH AND EAST OF ENGLAND HORTICULTURAL.

JULY 1.—The summer exhibition of this East Anglian Society was held on the above date in the Upper Arboretum, Ipswich, which, with the adjoining Christchurch Park, forms the principal of the open spaces in this town. The exhibits were accommodated in three tents, the largest being of considerable size, and in shape similar to the large marquee employed at the Shrewsbury Show for the fruit exhibits.

Visitors from London remarked the parched condition of the agricultural crops, and even the grass land, as seen from the railway, and we were afterwards informed that no appreciable rain had fallen in the Ipswich district since April; one of the residents observed that the last "rain" they had was "snow".

The arrangements for the show were in the hands of Mr. Harold R. Smith, and were satisfactory.

ROSES

This exhibition, being one of the earliest at which a good display of Roses is seen (following only a few days after Richmond and Windsor), it was interesting to observe the general quality of the blooms, and, allowing a little for the disadvantage of having to stage them in such extremely hot sunshine, the general quality was a further confirmation of the forecasts there have been made that the present Rose season will be one of the best for many years past.

The principal open class for 36 blooms, distinct, was won by Messrs. D. PRIOR & SONS, Myland Nurseries, Colchester, and this entitles the firm to hold for the year a Silver Challenge Cup. The collection contained a magnificent bloom of the new Rose, William Shean, a Hybrid Tea variety of rich pink colour and extra fine petals, which appears capable of remaining fresh for a considerable time under adverse conditions. Cultivators should take a note of this variety. Other good blooms were Ulrich Brunner, Bessie Brown, Mme. Jules Gravereaux, Dean Hole, Star of Waltham and Dupuy Jamain. 2nd, Messrs. B. R. CANT & SONS, who, however, obtained a R.H.S. medal for a bloom of Frank Karl Druschki, which was adjudged the best Rose shown in the open classes. 3rd, Messrs. FRANK CANT & Co., Colchester.

Messrs. D. PRIOR & SONS also won the 1st prize for twelve distinct trebles, being followed by Messrs. B. R. CANT & SONS. Messrs. FRANK CANT & Co. won the 1st prize for the best dozen blooms, distinct, of Tea and Noisette varieties.

The best variety in a class for six single blooms of a H.P. or H.T. Rose was Dean Hole, shown by Messrs. D. PRIOR & SONS, Mildred Grant, shown by Messrs. B. R. CANT & Co., being placed 2nd. The best Tea Noisette variety was Mme. Jules Gravereaux, shown by Messrs. D. PRIOR & SONS.

There were several exhibits in a class for nine bunches of garden Roses, distinct, and Messrs. FRANK CANT & Co. were placed 1st. In this exhibit there was an excellent bunch of the white variety Trier, and good ones of Irish Glory, Rubens, Una, and Papillon; Mr. R. C. NOTCUTT, Ipswich and Woodbridge, won the 2nd prize, and included a very fine bunch of Mrs. F. W. Flight.

In the classes reserved for amateurs, the best exhibit in the principal class, that for 24 blooms, distinct, was one from W. LEGGETT, Esq., the Rev. J. H. PEMBERTON being placed 2nd. In Mr. PEMBERTON'S exhibit a very fine bloom of Horace Vernet was awarded a R.H.S. Medal as the best Rose shown in the amateur classes. W. LEGGETT, Esq. won also the 1st prizes for eight distinct trebles, for 12 blooms distinct, and for 12 Tea or Noisette blooms distinct. In the classes for half-dozen blooms in the different sections, the best H.P. or H.T. variety was Fran Karl Druschki, and the best Tea or Noisette variety White Maman Cochet.

SWEET PEAS

formed the subject of several keen competitions, and most of the flowers evinced excellent cultivation. The best exhibit of 12 bunches, distinct, was shown by C. K. NORMAN, Esq., whose collection included excellent flowers of the new Saint George and Sutton's Queen; 2nd, Messrs. THOMPSON & MORGAN, Ipswich. Mr. E. V.

GOSTLING had the best collection of nine varieties, and Mr. W. H. BURROUGHS the best collection of six varieties. In another class in which prizes were offered by Mr. R. C. NOTCUTT, the 1st prize was won by the Hon. W. LOWTHER.

There were several classes for flowers of herbaceous plants, in which liberal prizes were awarded and good exhibits staged; also special classes for Delphiniums, Canterbury Bells, Iris, Gladioli, Anthriscums, and Pelargoniums.

The best group of miscellaneous plants arranged for effect was shown by H. J. SOUTHGATE, Esq., and the 1st prize in a class for smaller groups was won by W. P. BURTON, Esq. (gr. Mr. H. G. Strutt). Still smaller groups of the same class were arranged on a table, and in this class no plants could be over 3 feet in height. W. PIFE, Esq. (gr. Mr. J. S. Clarke) was awarded the 1st prize. Excellent "table" plants were shown in a class which called for six specimens. C. H. BERNERS, Esq., Woolverstone Park (gr. Mr. W. Messenger), had the best, and W. F. PAUL, Esq. (gr. Mr. W. E. Moores) was awarded the 2nd prize. Other classes for plants included Ferns, Begonias, Fuchsias, Hydrangeas, Verbenas, Gloxinias, and Schizanthus.

Some very pretty table decorations were contributed by ladies; the best in a keen competition was one from Miss A. F. HARWOOD, who employed rich Rambler Roses exclusively.

FRUIT AND VEGETABLES.

The 1st prize in a class for a decorated dessert table measuring 8 feet by 4 feet 6 inches was easily won by C. H. BERNERS, Esq., with an exhibit equal to those seen at the best shows. There were black and white Grapes, excellent Peaches and Nectarines, Figs, a Melon, and Strawberries. 2nd, the Hon. W. LOWTHER (gr. Mr. A. Andrews).

The principal prizes for vegetables were awarded as follows:—Hon. W. LOWTHER, 1st prize in Mr. R. C. NOTCUTT'S class, Messrs. FRED SMITH and Co.'s class, and the Society's class; C. H. BERNERS, Esq., 1st prize in Messrs. Webb & Son's class; all for collections of six dishes.

NON-COMPETITIVE EXHIBITS

were contributed by Mr. R. C. NOTCUTT, Ipswich and Woodbridge; Messrs. E. ARBOTT & SONS, Ardleigh, Essex; THOMPSON & MORGAN, Ipswich; JOHN K. KING & SONS, Coggeshall; WALLACE & Co., Colchester; FRED SMITH & Co., Ipswich; Mr. C. H. BUCK, Ipswich; and Mr. AMOS PERRY, Winchmore Hill, London. Mr. PERRY exhibited a plant of *Stokesia cyanea* alba, which was awarded a Certificate of Merit.

THE WEATHER.

THE WEATHER IN WEST HERTS

Week ending July 1.

The warmest week as yet this year. The past week proved, on the whole, very warm. On five days the highest reading in the thermometer screen rose to, or exceeded, 75°. The nights, on the other hand, were as a rule only moderately warm, and on one night the exposed thermometer fell to within 5° of the freezing point. On one day the heat from the sun was very great, the highest reading of the bright bulb thermometer in vacuo being 96°, while the black bulb thermometer in vacuo registered 140°. Both thermometers are mounted 4 feet above the lawn. These readings are very high even for a summer month. The ground has become lately much warmer, and the soil is now 2 feet deep, and 5° warmer at 1 foot, than is reasonable. No rain has now fallen for a fortnight. There has been no percolation at all through the gauge on which short grass is growing for over three weeks, but a few drops still come each day through the bare soil gauge. The sun shone on an average for nearly 100 hours a day, or for four hours a day longer than is usual at this season. On the brightest day of the week the record amounted to 13 hours. Light airs from some northerly point of the compass exclusively prevailed. The mean amount of moisture in the air at 3 o'clock in the afternoon fell short of a reasonable quantity for that hour by nine per cent. E. M. Bekhamsted, July 1, 1908.

SCHEDULES RECEIVED.

Cambridgefield Horticultural Society's summer show to be held on Thursday, July 9, in St. John's College Grounds, Cambridge, and autumn show on November 11 and 12 in the Corn Exchange. Hon. Sec., Mr. Arthur Matthews, 29, Trinity Street, Cambridge.

Hereford and West of England Rose Society's 17th annual exhibition to be held at the Corn Exchange, Hereford, on Wednesday, July 15, 1908. Hon. Secretary, Mr. F. A. Speer, The Barcott, Hereford.

ABNORMAL FLOWERS OF DIGITALIS: F. C. E.

The flowers you send have become regular and present an instance of the condition known to botanists as peloria. This abnormality is common to plants of the Foxglove family, and is probably due to reversion. We often receive flowers similar to those you send.

APPLE BLOSSOM FALLING: T. C. This may be due to a variety of causes; it may follow as the result of imperfect fertilisation, injury by frost, constitutional weakness in the tree, &c.

ASTERS DISEASED: A. J. & C. Brest. The disease affecting your Asters is not understood, and no remedy is known. It is not caused by a fungus.

CORRECTION.—On p. 415 for *Spiraea primifolia* read *Spiraea prunifolia*.

CUCUMBER SPOT DISEASE: E. P. Clevedon. There are several preparations on the market for combating this disease; you can obtain particulars of them from the horticultural sundriesmen. Have you tried spraying the plants with potassium sulphide?

FIGS DISEASED: G. H. B. & Ancibus. The disease is caused by a fungus (*Botrytis cinerea*). The pest is only able to exist in the presence of imperfect ventilation. From this cause there is too much contrast between the night and day temperature, and, as a result, moisture condenses at the end of the fruits and enables the fungus to gain a footing.

GRAPES DISEASED: H. Alubank. The berries are affected with the spot disease (*Gloeosporium*). The diseased berries should be removed and burned as speedily as possible. You should be dusted with flowers of sulphur at intervals of ten days. On the second application put a little quicklime with the sulphur and increase the quantity of lime each time, but never have a greater amount of lime than sulphur. Next winter wash the plants with sulphate of iron in solution.

INSECTS ON CERASUS PADUS: H. H. C. The caterpillars attacking your trees of *Cerasus Padus* are those of a small moth—*Hypomoneta padi*—which belongs to the same genus and very much resembles the small ermine moth *H. padellus*. The best method of destroying them is to remove the nests, holding a cloth or something similar under the trees to catch any of the inmates which may fall out during the operation. Spraying the nests with a strong solution of paraffin should prove useful in destroying the pest, if sufficient force can be used to break the webs. Spraying the leaves with arsenate of lead wash or with Paris green (poison) will destroy the caterpillars.

LILACS ON THEIR OWN ROOTS: Correspondent. The plants are readily propagated from suckers, which spring in plenty from the roots. If you find a difficulty in obtaining sufficient suckers for your needs, layer some of the shoots nearest to the ground.

MAGGOTS AT THE ROOTS OF CABBAGES, &c.: C. W. These are the larvæ of one of the Cabbage-root flies, probably *Anthomyia radicum*, which is the commonest of the three known species. Dig up and destroy the infested plants. Give the land a dressing of gas-lime in the autumn; and change the crop. For cabbage and onion crops use artificial manure in the place of stable manure. Keep the soil firm and close over the roots of the plants, and in dry weather supply them with plenty of water, to which a little liquid from stable manure may be added. Stable manure often encourages the presence of these maggots, for they feed upon it, or any other kind of decaying vegetable matter.

MILDew ON STRAWBERRIES: W. H. Y. Ventilate the house more freely, but at the same time guard the plants from direct cold draughts of air.

NAMES OF PLANTS: J. W. *Phacelia tanacetifolia*.—C. H. P. *Cerastium tomentosum*.—*A. pinn.* 1. *Veronica Teucrium* var. *dubia*; 2, *Helianthemum vulgare* var.; 3, *Belagomum affine*; 4, *Thymus Serpyllum* var. *pulchellus*; 5, *Thymus Serpyllum*; 6, *Helianthemum vulgare* var.—S. Taylor. 1 and 2, what miserable specimens! they are too scrappy to identify; probably varieties of *Philadelphus*; 3, *Quercus flex*; 4, probably *Spiraea Lindleyana*; 5, *Berberis stenophylla*.—*Vitis*. 1, *Clematis Jackmanii* var.; 2, *Sedum rupestre*; 3, *Stachys grandiflora*; 4, *Veronica caucasica*; 5, *Geranium* (too withered to identify the species); 6, *Cistus salvifolius*.—G. H. 1, *Phacelia stylosa*; 2, *Genista sagittalis*; 3, *Orphys aptera*.—T. W. N. 1, not recognised; 2, *Allium neapolitanum*; 3, *Anthericum Liliago*; 4, *Hesperis matronalis flore pleno*; 5, *Iris sibirica*; 6, *Campanula persicifolia* var.—*Eagle*. *Tecoma jasminoides*.—W. R. 1, *Cheledonium majus*; 2, *Gilella trifoliata*; 3, *Laurus nobilis* var. *angustifolius*; 4, *Echeveria* sp.; 5, *Helxine Soleirolii*.—W. S. & Sons. 1, *Eurya japonica latifolia variegata*; 2, *Euonymus japonicus latifolius aureus*.—J. D. *Eranthemum Andersonii*, figured in *Bot. Mag.*, t. 5771. Native of India.—J. J. F. 1, *Dendrobium Incaumatum*; 2, *Dendrobium moschatum*; 3, *Cypripedium Chamberlainianum*; 4, *Aerides odoratum*.—W. R. P. 1, *Dieffenbachia eburnea*; 2, *Eranthemum atropurpureum*; 3, *Strobilanthes Dyerianus*; 4, *Pittonia argyrorenea*; 5, *Pittonia l'earcei*; 6, *Pellonia Davaeanua*; 7, *Pellonia pulchra*.—F. F. *Campanula glomerata*, an old garden species.—A. H. *Dendrobium transparens*.—*Cymra*. 2, the grass is probably *Festuca arenaria*, but the specimen is very scrappy and no information is given as to the country or locality in which it was found.

NYMPHFA LEAVES INJURED: B. L. The foliage is not diseased, but has been eaten by some aquatic insect. You should employ the fountain and scrub line system with a solution of soft soap and paraffin, using one gill of the latter to each gallon of water. Wash the soil from the roots of the plants before they are returned to the water.

PEACH LEAVES WITH HOLES: Eigob. The holes are caused by the shot-hole fungus (*Cercospora circumscissa*). You should gather and burn all the affected foliage, as the disease spreads quickly, the spores being present on the portions of the leaves which have dropped out. Mr. Geo. Masee, in his book of *Plant Diseases*, recommends spraying with ammoniacal solution of copper carbonate, the first time when the leaves are expanding and repeating the spraying at intervals. Bordeaux mixture should not be used for spraying Peach or Almond, as the leaves, and even the young shoots are injured by dilute solutions of this insecticide.

PEA FOR NAME: H. J. P. The purple-podded Pea, a well-known variety of *Pisum sativum*.

PINES PARVIFLORA ATTACKED BY FUNGUS: T. J. & Son. The fungus present on the shoot you send is *Peridermium pini*, and it will spread to other coniferous trees unless it is checked. If the trees are badly attacked they should be cut down and the diseased portions burned. The second form of the fungus grows on the leaves of various wild kinds of *Senecio* (*Grondsel*), &c., forming powdery orange patches. All weeds of Composites should be destroyed, as the spores from these infect the Conifers, and the spores formed on the Pines infect the *Grondsel*, &c.

POPULAR LEAVES INJURED: F. G. The galls on the leaf stalks of the Poplar are produced by the aphid *Pemphigus bursarius*. This insect rarely occurs in sufficient numbers to cause serious injury to the trees, but in your case they seem to be unusually abundant. We doubt if spraying with quassia or any other form of insecticide would be of any use; collecting and destroying the galls early in the season would materially check their increase.

POTATO MOTH: C. C. S. We suspect you refer to the Death's Head Hawk Moth (*Acherontia atropos*). If you will send us a specimen we will endeavour to furnish you with the particulars you require.

POTATOS: *Puckled One*. We cannot give an opinion in the absence of specimens.

PROLIFEROUS CARNATIONS: W. A. W. The blooms you send present the abnormal condition known as proliferation. Owing to some cause, the centre of the flower, instead of remaining arrested in its growth, has lengthened, and in your example is producing another flower. The cause is difficult to determine, but no doubt it is in a large measure due to excess of vigour in the plant.

SEEDING TOMATOS, &c.: H. R. By thinning out the bunches of the fruits that remain will receive extra nourishment, and in consequence the seeds will be finer and give better results. Apply the basic slag in the autumn and, in the following spring, as the ground is deficient in lime, some mortar rubble, which will be better than using the more caustic quicklime. The other query involves a legal question. The meter having failed in its purpose, we should think it unreasonable to be required to pay for its hire. The contribution has been placed in the R.G.O.F. box.

SITUATION IN ENGLAND: S. H. R. You would probably find considerable difficulty in getting such a situation, but you may easily determine this by advertising. One hundred pounds a year, with the usual allowances of house, &c., would be a liberal wage for the position you describe.

STRAWBERRIES DISEASED: E. W. & E. C. The disease is Strawberry-mildew (*Sphaotoclea castagnei*). It is too late to adopt any measures to save the present crop, but next spring, when the leaves are expanding, spray them with a solution of sulphide of potassium, one ounce in four gallons of water. Continue the spraying at intervals of ten days until the fruits are half-grown. Take care to spray the under surface of the leaves.

SWEET PEAS: W. J. C. Most varieties of Sweet Peas are more or less fragrant.

TOMATOS DISEASED: A. I. Your plants are affected with the leaf-spot disease. Spray the foliage every third day with a solution of potassium sulphide in the proportion of one ounce to three gallons of water. Destroy by burning the worst of the affected plants. When using the potassium sulphide, remember that this chemical substance turns paint black.

W. H. Your fruits are attacked by the black spot disease (*Cladosporium lycopersici*). You will find an illustration of this disease and remedial measures given in the *Calendar of Garden Operations*, which may be obtained from our publishing department for 7d., which includes the postage. We extract the following:—"The spores of the fungus are supposed to gain entrance to the fruit through minute cracks or punctures in the skin; therefore, the use of green stable manure, and of anything likely to induce cracking in the fruits, should be avoided. Over-watering has this effect. As a preventive, ventilate freely, exercise vigilance, and spray the plants at frequent intervals with potassium sulphide prepared as follows: Dissolve one ounce of potassium sulphide (liver of sulphur) in a quart of hot water; then make up to two and a half gallons with cold water. Feed the plants with manure water."

TOMATO STAINS ON THE HANDS: H. R. Try the effect of methylated spirit, as chlorophyll, the green colouring matter of plants, is soluble in spirits of wine or methylated spirit. If this fails, place a small quantity of hydrochloric acid (spirits of salts) in the water in which the hands are washed, but be careful to use this very strong fluid with caution.

TREE CAUSING DAMAGE TO WALL: G. K. Y. From your account there seems to be no doubt but that you are responsible for the damage caused by the tree in falling on your neighbour's wall. As it involves a legal question, your best plan will be to consult a solicitor.

MIDSUMMER DAY IN THE WISLEY GARDEN.

Two years ago I tried to describe the spring glory of the garden. But the bright procession of the year moves rapidly—"Ver proterit .Æstas"—the fresh youth of proud-pied April pales before the sumptuous maturity of June; and the visitor on Midsummer Day finds his earlier favourites supplanted by a more opulent, if not lovelier, flora.

Fortunate is the stranger whose walk round the garden is enlivened by the horticultural enthusiasm and practical knowledge of its superintendent, Mr. Wright. On the lovely afternoon of June 24 this great advantage was ours, and we were joined by an accomplished amateur whose unpretending garden carries off annually a majority of the prizes offered at a local flower show. We entered between wide borders, barren two years ago, filled now with Roses as yet of no great stature, but full of splendid bloom.

Among the finest over which we lingered were Mme. Abel Chatenay, Mrs. W. J. Grant, La Tosca, Lady Roberts, Mme. Vermorel, Souvenir de S. A. Prince, Edith Gifford, Mme. Capucine, with its exquisite yellow buds shaded by metallic-red, Bessie Brown, Lady Waterlow, and Caroline Testout.

We entered the herbaceous ground under a canopy of flowering shrubs, which, as we looked back from time to time, formed walls of harmonious colouring. Spiræa aruncus tossed its white foam everywhere; one grand bush, in contradiction to its water-loving habit, anchored on a dry rock, sucking moisture somehow out of unseen crevices and fissures. There were masses of Rubus odoratus, the blooms pink in the sun, in the shade a red almost deepening to native Canadian purple, mixed with the white variety distinguished formerly as Nutkanus. Next came Viburnum plicatum, succeeding and emulating its spring sister, the native Guelder Rose, and our guide told us that no plant drapes a north wall so successfully. Philadelphus, scented or scentless, dropped its fugacious petals on our heads; adjoining them are Lupinus, white and yellow, with Spartium junceum, the mistranslated "Juniper tree" of our Bibles, under which the cowed prophet, flying from the face of angry Jezebel, lay down to sleep. The ponds have only just ceased to show the Hawthorn Water Lily, Apogoneton distachyon, which on our former visit filled half the garden with scent; that is replaced by M. Marlie's beautiful pink Nymphaea ignea, with pale olive-green, rose-edged sepals, imbricated crimson petals growing in a whorl around stamens of a vivid orange-red, mingled with the large white Water Lily N. Gladstoniana. One pool shows the small round floating leaves of the fringed Buck-bean, Villarsia nymphaeoides, under which a colony of Canadian bull-frogs have made their home, the amorous males from time to time uttering their raucous love-note, met by their responsive mates with croakings even less melodious; the yellow blooms, not yet showing, will, in a month's time, we are told, cover the surface of the water. The ponds are bordered on the hither side by Irises of every hue, some of great size, varieties raised by seed from I. Kœmpferi. The steep further banks are hidden by the vast leaves of Gunnera manicata.

We pass from the waterside into the shade of trees. A rift in the ground, moistened by a slender stream, has the choicest hardy Ferns, which indeed range all around, from tall Osmunda to the dwarf Lonicitris. In a wet corner flourishes in unusual dimensions Primula japonica, its tall flower-stems covered with green berries. A Japanese gentleman who admired it here in flower was puzzled in this and other cases by the specific name, declaring that none of the plants so called were familiar to him at home. Here under the trees are established shade-loving plants. We notice Chrysogonum virginianum, whose flowers make an autumn show, springing from the axils of the leaves; the splendid Gentian, G. asclepiadea; Meconopsis Wallichii, a

triumph of horticultural love and care, growing already 5 feet high, its pale blue blossoms not yet open, but the characteristic bright bronze hairs already covering the stem; and near it the azure flowers of the Chinese M. racemosa. In a more open spot is a fine collection of Cyripediums; alone of our common English Orchids, O. maculata is everywhere seen. We walk between tall hedges of Camellia, which freely flower in their season; one Rhododendron, Duchess of Connaught, is showy still; a bed of seedlings from the Himalayas promise future splendour; Azalea occidentalis is full of bloom and fragrance. We note the beautiful ericaceous Zenobia speciosa, with white wax-like flowers closely resembling Lilies of the Valley, and the allied Pieris floribunda and mariana. We knew them formerly as Andromedas. One plant, A. polifolia, still happily commemorates the delicate fancy of Linnaeus. Hard by towers the grand Phormium tenax, 2 feet higher than we saw it here before. Mr. Wright tears a slender fibre from one of its leaves, and challenges our amateur—a powerful man—to break it. He fails, as Samson might have done; it is used in Egypt as a tow-rope for boats on the Nile. The pretty lemon-coloured flowers are not at present showing.

Of the garden trees three especially arrested us: Prunus Pissardi, with cherry-like fruits shining amid its rich brown foliage; Cut-leaved Alder, Alnus laciniata imperialis, uncommon in this country (a noble specimen grows in New College Gardens, Oxford); and Sciadopitys verticillata, pronounced to be the Umbrella Pine—a splendidly-grown Conifer, with scant resemblance to an umbrella, and certainly not the tree shown under that name to travellers on the Riviera. But the commoner trees have charms, for on them are disposed nesting-boxes, procreant cradles for fowls of the air, protected here no less reverently than Lilies of the field. We peeped into one from which a wryneck had just taken temporary flight, and saw her six white eggs lying naked on the bottom; for the wryneck, building in mouldering tree-holes, does not need to line its nest with leaves or moss. The birds are absolutely tame; the sitting hen, of the thrush-kind especially, will allow its head to be stroked by a human hand.

The rockery, thinly clad in 1906, hides its projecting stones to-day amid foliage and flowers. We paused to admire Digitalis ambigua, yellow and more stately than the better-known D. lutea; a remarkable Dianthus cross with a Sweet William and a Pink, known as Lady Douglas; the Australian Oleandra or Daisy tree, valuable as a covering to dry banks, and the little known but easily reared Pentstemon atrorhizum, with flowers of china-blue. Our conductor reserves to the last the most gorgeous of his shows—a bed of 500 Peony varieties not yet gone by, and a greenhouse filled with Cannes which bid the rash gazer wipe his eye. With grateful hearts and well-stored memories we pass out through the gate of Paradise, murmuring to ourselves Tom Moore's forgotten lines:—

"And oh! if there be an Elysium on earth,
It is this! it is this!"

—Corycius Senex.

NURSERY NOTES.

MESSRS. V. N. GAUNTLETT & CO.,
CHIDDINGFOLD, SURREY.

ABOUT two and a half years ago, Messrs. Gauntlett moved from their Redruth Nursery in Cornwall to Chiddingfold. They found Redruth much exposed to winds, and the soil there was poor in quality, so they looked about for a fresh site. They eventually settled on Chiddingfold, where the soil is a very heavy loam, with a subsoil of sandy clay, which retains moisture well, the top loam being very deep, in some places fully 5 feet. When they took possession, the ground was covered with heavy brushwood, but this was grubbed, and the soil double-trenched to a depth of 2 feet. The expense entailed in this operation was well repaid, for the plants flourished in the soil, even in seasons of exceptional drought. Soon after moving from Cornwall a period of 16 rainless weeks was experienced, but few plants succumbed, even after the long journey from Cornwall. The nursery is situated in a gentle hollow surrounded by well-wooded hills, and, along its lower limits, it is bounded by a stream, by the sides of which are planted Bamboos and other moisture-loving plants. Bamboos, of which the stock consists of more than 10,000 specimens, flourish as well as they do in Cornwall. *Arundinaria palmata* is represented by fully 1,000 plants. Twelve plants of this species that were planted out from 6-inch pots now form a clump 30 feet through. Of the Japanese Cherries, fully 10,000 are grown, and of *Pyrus Malus floribunda* Messrs. Gauntlett have sold 5,000 in one year. There is a fine collection of *Acers*, among these being *A. pseudo-platanus* brilliantissima, having leaves, when expanding, of a bright pink colour. *A. atropurpureum* variegatum, *A. colchicum rubrum* (with young leaves of a rich purple), *A. Leopoldii* variegatum (with handsome white and green foliage), and *A. Golden King* (with bright yellow leaves, which do not burn in the sun). At the time of my visit large masses of tree Peonies were in full flower, and the herbaceous Peonies were in the best of health. Many plants that are associated with Cornwall succeed also at Chiddingfold. *Gunnera manicata* has made splendid growth, and has already leaves 7 feet in diameter. *Phormiums* are doing well, and there is a walk edged with good specimens of Palms, and many species of *Yucca*. Some plant houses and frames are constructed of narrow strips of wood, with interstices of the same width as the laths between. These structures tend to mitigate the effect of frost, and in the summer they provide welcome shade and shelter from the sun's rays. In one of these houses tree Ferns and Palms were looking well. Two specimens of *Dicksonia antarctica* are, indeed, grown permanently in the open, their leaves being cut off in the autumn and their trunks wrapped in bracken. These never fail to push forth strong leaves in the spring. In one of the lath frames Himalayan Rhododendrons were growing vigorously, and in another *Vitis Henryana*, with most of the new vines. In the propagating house, which is fitted with eight rows of hot-water pipes, were *Mutisia decurrens*, *M. Clematis*, *Berberidopsis corallina*, *Aciphylla Lyallii*, *Lomatia ferruginea*, *Solanum aviculare*, *Plagiathus grandiflora* (with larger flowers than *P. Lyallii*), *Buddleia Colvillei*, *Tricuspidaria dependens*, *T. lanceolata*, *Vitis Thunbergii*, *Rhaphitossam cyanocarpius*, the pretty, pale yellow *Rosa Hingonis*, *Distylium racemosum*, the Silver Tree (*Leucadendron argenteum*), *Gordonia lasiantha*, *Maytenus ilicifolia*, *Elaeodendron sphaerophyllum* (which was sent out as *Guevina Avellana*), and a batch of young plants of *Pinus Montezumae*. In a cool house were growing *Bauera rubioides*, a shrub that would probably be hardy in Cornwall, with small pink flowers;

Cistus immaculatus, pure white, which appeared to be the white type of *C. Iadamerus*, which is almost unknown in England; *Stranvaesia glaucescens*, with white flowers; the new *Viburnum rhytidophyllum*; *A'ebia lobata*, quite distinct from the better-known *A. quinata*; the yellow-flowered *Genista germanica*, *G. mopsulensis*, *G. Hildebrandtii*, the yellow-blossomed *Hermannia candicans* from Australia; *Viburnum hydrangeoides*, *Citharexylum quadrangulare*, *Carpenteria californica*, *Erica arceuthifolia*, yellow; *Chionanthus retusus*, *Azalea Scillopenbachii*, *A. Tebotan*, a number of small plants of *Embothrium coccineum*; Himalayan Rhododendrons, and *Pittosporums*. The rare *Olearia insignis*, *Edwardia* (*Sophora*) *microphylla*, and a fine batch of the beautiful *Veronica Hulkeana* were also noticed. A newly-constructed tank contained Water Lilies in tubs. In another lath frame were *Fabiana imbricata*, *Rubus australis*, and *Arbutus canariensis*. *Iris Kämpferi* is grown in large quantities, the stock last year numbering 30,000 plants, of which rather less than half that number were sold, leaving 16,000 this year. The many varieties of *L. sibirica*, including the beautiful *Snow Queen*, were also present in quantity. All the known species and varieties of *Spiraeas* and *Astilbes* are grown, and there is a large group of *Cortaderia* (*Arundo*) *conspicua*. In the damp ground by the stream are planted *Polygonums*, *Gaultheria Shallon*, *Primula sikkimensis*, *P. japonica*, and *P. rosea*. Among the hardier Rhododendrons a fine group of the lovely *Pink Pearl* was inspected. *Roses* grow luxuriantly. *Wichuraiana* varieties developing in one season groups 15 feet in length. Of *Weigela* (*syn. Diervilla*), *W. argentea-variegata*, with white-margined foliage, *W. Conquete*, with very large rose-coloured flowers; *W. Eva Rathke*, marooned, and *W. Mont Blanc*, the best white variety, were pointed out. Of the *Laburnums* the most noteworthy was that known as *Vossii*, with very long flower trusses, which are said sometimes to attain to a length of two feet. Several varieties of *Pyrus japonica* are grown, amongst which were *Aurora*, with large, salmon-pink flowers; *cardinalis*, rose; *coccinea*, scarlet; *nivalis*, white; *Sargentii*, a dwarf variety from Japan, with bright red blossoms, and *superba*, a form with trailing habit and bearing large, waxy, scarlet blooms. Of *Magnolias* there were seen *M. glauca*, *M. hypoleuca*, *M. Kobus*, *M. Lennei*, *M. Osaka*, *M. parviflora*, *M. stellata*, *M. Soulangiana*, *M. S. nigra*, *M. tripetala*, *M. Campbellii*, *M. Watsonii*, *M. grandiflora*, and one labelled *M. compressa*, with small, evergreen foliage. Among other noteworthy plants, either in the open or under cover, were *Aralia Maximowiczii*, 8 feet in height; the New Zealand *Aristolochia racemosa*; *Azalea Anthony Koster*, *A. Omurasaki*, *Andromeda arborea*, *Ceanothus rigicus*, which survived the winter in the open, as did some of the *Eucalypti*, *Cornus florida rubra*, *C. Kousa*, *C. Nuttallii*, *Corylopsis pauciflora*, the new *Davidia involucreta*, *Desfontainia spinosa*, *Casalpinia gilliesii*, *Evochorda Albertii macrantha*, with larger flowers than the type; the new Chinese *Hamamelis mollis*; *Hoberia populnea*, from New Zealand; the recently-introduced *Lonicera fragrophylla*; *L. tatarica*, *Adenocarpus anagyris*, the lovely *Anopterus glandulosa*, *Camellia reticulata*, the rare *Crossosoma californica*; *Daphniphyllum glaucescens*, *Drimys aromatica*, *D. Winteri*, *Elaeocarpus reticulatus*, the beautiful *Eucryphia pinnatifolia*, and the rarer *S. cordifolia*, *Feijoa Sellowiana*, a handsome flowering evergreen; *Fremontia californica*, *Grevilleas* of several species, *Hallimodendron argenteum*, the Japanese *Idesia polycarpa*, *Ilicium anisatum* and *I. floridanum*, the South African *Leonotis Leonorus*, *Loropetalum chinense*, the brilliant *Mitrasia coccinea*, the Australian *Myoporum laetum*, whose leaves are covered with innumerable transparent spots; *Neviusia alabamensis*, the Alabama snow-wreath; *Notospartium Carmichaeliae*, the

New Zealand pink Broom; *Osteomeles anthylidifolia*, *Philsea buxifolia*, *Pieris formosa*, *Rodgersia æsculifolia*, *Semiele androgyna*, *Senecio chlorum*, *S. Wilsonii*, the new *Spiraea Aitchisonii*, *Viburnum Awafukii*, the rare *V. Sieboldii*, and *Xanthoerax sorbifolia*. The nursery is an extremely interesting one, and is within easy reach of London. *S. W. Fitzherbert.*

NOTES FROM A "FRENCH" GARDEN.

WE are now cutting Melon fruits from plants that were put out at the end of March. The weather was very trying in April, but we were able to preserve the plants in health by keeping the conditions about them very dry. There is not a stage in the growth of Melons when the cultivator can afford to relax the attention given to them. Now at the period of maturity he must carefully watch the plants, especially during the hot and sunny weather prevailing, and gather each fruit when it is sufficiently ripe. This is indicated when the base of the stalk is marked by a white line, and if the fruit were not gathered then the stalk would part from the fruit, which would thus lose in appearance. As soon as Melons are cut they are removed to a cellar, where they remain for two or three hours in order to get cool before being sent to market. The fruits are at their best on the following day. At the present time all the Melon plants require an abundant supply of water, with plenty of ventilation, and the plants are greatly benefited if the lights are left partially open at night. The first batch of Cauliflowers is exhausted, the second batch planted between the first lot of Cos Lettuces, the third batch planted amongst the Passion Lettuces in April, and the fourth batch, which was planted in the open ground, are all growing freely, and it is necessary to water them very frequently. We are now planting Cauliflowers among the first batch of Melons, putting four plants under each light. These Cauliflowers are planted two months after the setting of the Melons, excepting that it is not advisable to plant before the end of June, as it is not practicable before that date to apply the necessary amount of ventilation for the well-being of the Cauliflowers.

The beds which were occupied by the Carrots and Cauliflowers had been prepared for Endive and Celery. The beds were previously cleaned by hand. All the paths, Nos. 3, 5, 7, 9, 11, &c., are dug out and the soil and manure taken from them are thrown on the beds on either side. The beds are then dugged in the usual way, the empty paths being made level with the soil from the beds. The beds are next trodden as evenly as possible, and mulched with well-broken manure. If Spinach and Radishes are required as catch crops they are sown when the beds have been trodden. The next work is to drill the beds. We set the line against the outside path from one end of the bed to the other. The workman, wearing a pair of clogs, passes along the line, his left foot against it; dragging both legs he drills two rows at a time, 18 inches apart. The second journey he used the second drill for a guide and so on, using the line only for the first row. The beds are watered once or twice as required before the planting of the Endive and Celery. When planting we stand on a board which is set across the bed. We plant the second, fourth, sixth, eighth, and tenth rows 9 inches from the board without using a line. The plants always appear straight from whatever direction they are seen. If a considerable quantity of Endive be required, this is the time to sow the last batch; also a batch of *Batavian Green*, to be planted out in the field in August. *P. Aquilias, Mayland, Essex, June 29.*

CLIANTHUS PUNICEUS ALBUS.

THE *Clianthus* is generally regarded as a greenhouse climber in this country, but in favoured districts like the south-west of England the plant will flourish well in the open, the only protection necessary being a warm wall. The plant illustrated at fig. 8 is growing in such a situation and represents the albino form, which is a pleasing addition to the scarlet-flowered type. The name *Clianthus* means glory flower, in allusion to the beautiful colour and form of the blooms; it is popularly known as the Glory Pea. Cuttings root readily in sand, provided they are started with a gentle bottom

by Christmas Day, and from that time onward blossoms are borne in ever-increasing numbers, which reach their greatest profusion in May. Specimens of the scarlet *Clianthus* grown in bush form do well in the south-west, and flower with freedom. It is, however, certainly seen at its best on a wall, as it presents a larger expanse of colour than when grown as a shrub. Very large specimens are to be seen in the south-west, one having covered the side of a house to the eaves, a height of over 20 feet. In addition to Glory Flower, the plant is sometimes known by the names of Lobster Claw and Parrot's-bill, from the curious shape of its flowers. The white variety is not of a pure

has hardly been injured. Here, as soon as the flowers are faded they are all cut off, as otherwise thousands of seed-pods would be formed, and this would inevitably greatly weaken the plants. After the removal of the flowers the plants are heavily syringed every evening, this being continued through the entire growing season. The eaves projecting over the plants prevent the rain from falling on them, and if they were not syringed the foliage would soon suffer. When they become dry they are attacked by myriads of green fly, which so weaken them that but little new growth is made, but with copious syringing every evening these pests never make their appearance. When the growth is completed, the new shoots are laid in behind the vines, so that the wall is entirely covered with foliage and no glimpse of stone is to be seen. S. W. Fitzherbert.

MULCHING.

PEAS and Beans will be considerably benefited by having a mulching 4 inches thick of half-decayed manure as a means of conserving the moisture at the roots, as well as stimulating the growth. The mulching should be put on as soon as the rows of Peas and Beans are earthed up, and the former staked, after which, in the event of the weather being dry at the time, a good watering should be given. Fruit trees, such as Peaches, Cherries, Apricots, Plums, Figs, &c., planted at the foot of and trained up against walls having south, west, and east aspects, will also yield better results by having a layer of a few inches of manure placed on the surface of the soil immediately over the roots, 4 or 5 feet from the base of the individual trees, the soil having been previously slightly loosened on the top with a digging fork. Subsequent waterings will wash the substance of the manure down to the roots, to the advantage of the trees, and will help to develop heavier crops of finer fruits than would otherwise be obtained. Beds of Pelargoniums, Calceolarias, Stocks, and Asters may, by the application of a surface-dressing of short manure or leaf-soil, be furnished in a little more than half the time the plants would otherwise require to cover the surface of the beds with flowering shoots. A good mulching of short manure laid on between rows of Raspberries will also be productive of the most satisfactory results; more especially is this the case during a dry, hot season. H. W. W.

NOTES FROM LA MORTOLA.**SHRUBBY AND SOFT-WOODED COMPOSITE.**

LARGE shrubby, and soft-wooded Composite, such as *Montanoas*, form an important feature in our southern gardens. It is only in such places that they can be seen to full advantage. In houses they soon look shabby, and in many instances are not worth the space they occupy. Here with us it is quite different. We always welcome new shrubby Composite. The *Montanoa mollissima* (Brong.) was figured in *Botanical Magazine*, t. 8143, from a plant which came from this garden. *Montanoa pyramidata* (C. Koch) is exceedingly effective in December, when the Imperial Dahlia (*D. imperialis*) is over, a plant which of course cannot be surpassed for majestic beauty.

Another such shrub which flowers from November to January, but by no means as pretty as the plants just mentioned, is *Montanoa tomentosa* (Llave), of which the form *cordifolia* (D.C., V., 664) has been distributed from the Villa Thuret through Prof. Poirault. It is a shrub about 2 metres high, about the size of *M. mollissima*. It has cordate and coarsely dentate leaves. The flower-heads stand in great axillary clusters at the top of the branches, the individual flower-head being but small, with five white ray florets. Nevertheless the plant as a

(Photograph by S. Wyncham Fitzherbert.)

FIG. 8.—THE WHITE FLOWERED VARIETY OF CLIANTHUS PUNICEUS.

beat. The plants grow vigorously when established, and are suitable for covering the roof rafters of walls of the greenhouse or conservatory.

The white variety was introduced into commerce a few years ago, and is now to be met with in many gardens. The type was introduced into this country more than 70 years ago, and is common in Devon and Cornwall, where it makes a grand show in May, walls on which it is grown being a sheet of scarlet at that time. A few flowers of the type may generally be cut

snow-white, but is tinged with faint green, and where only one can be grown the scarlet type is to be preferred, as it is far more striking in appearance. However, when the two are grown on the same wall, as they are here, they make a pleasing contrast. The type is about 18 feet in height, and the white form, which has not been in many years, 7 feet, and both flower with equal freedom. The *Clianthus* may be considered perfectly hardy in Devon and Cornwall, for even in the last two winters, which have been unusually severe for that district, it

whole is a very pleasant sight whilst in flower. It is also a native of Mexico. It grows easily from cuttings, and deserves a place in every garden in the south, where winter-flowering plants are ever welcomed. Another Montanoa, in habit, somewhat intermediate between *M. mollissima* and *M. pyramidata*, flowered last January for the first time. I owe it to the kindness of the well-known Dr. Carl Werthe, in Costa Rica, who sent me seeds of this and of many other interesting plants from his rich country. This plant has not yet been determined. It has proved a quite hardy and decorative addition to our garden flora. I shall publish a full description of it later on. To the same gentleman I also owe the introduction of a plant, which was determined at Dahlem by Prof. Hoffmann, the well-known authority on Compositae, as *Verbesina diversifolia* (D.C., V., 615). It is a large evergreen bush, about 3 metres high and nearly as broad. Its leaves are alternate along the stem. They measure, inclusive of the broad-winged petiole, about 40 centimetres, and are bipinnatifid and hispid. The wings of the petiole are decurrent along the stem. The flower-heads are small, not unlike some *Achillea*, but united in great quantities on long peduncles in broad and flat cymes of a pure white. The flowers appear just at Christmas, and last till February, and as the plant is of striking beauty it is well worth planting freely. Even when without flowers it forms an interesting object. I hope to be able later on to distribute cuttings and seeds of this new shrub among our correspondents. Unfortunately I have no opportunity to compare my plant with herbarium specimens of this species, which, according to de Candolle, is a native of Bahia, whilst my plant is a native of Costa Rica. Its native name is Toona. Perhaps it may finally prove to be a new species. In habit it somewhat resembles the figure 162 of *Verbesina pinnatifida* (Lav.) in Nicholson's *Dictionary of Gardening*. This, however, has opposite leaves and pale yellow ray flowers.

Another Mexican Composite of a similar habit to those already mentioned was received a few years ago from Dr. F. Franceschi from Santa Barbara, namely, *Tithonia diversifolia* (A. Gray) or *Mirassolia diversifolia* (Hemsley). It forms a broad and roundish plant with spreading, robust branches and alternate leaves, somewhat resembling a *Helianthus*. The flower-heads are borne, about three in number, on short and thickened peduncles at the end of the branches. The individual flower-head is rather large, with rich golden-yellow ray florets, measuring about 9 to 10 centimetres across. It cannot be called a very attractive plant in spite of the beauty of the flower-heads on account of its rather unpleasant habit, although it is a very interesting plant and worthy to be grown here, especially as it flowers in the middle of winter, at the beginning of January. *Alwin Berger, La Mortola, Italy.*

ORCHID NOTES AND GLEANINGS.

SOBRALIA MACRANTHA ALBA

A FINE specimen of this Orchid, bearing many large pure white blooms on the highest points of their tall reed-like stems, is in flower in the gardens of J. S. Berghem, Esq., Belsize Court, Hampstead (ed. Mr. H. A. Pace). The purity of its snow-white flowers contrast well with the deep rose-purple colour of the specimens of the typical variety which are arranged with it. This is a true albino, in which the colour of the type never appears; whereas, in some, such as *Cattleya Trianae* alba and *C. Schroderae* alba the plants may bear white blossoms one year and slightly rose-tinted the next. An interesting lot of Catacetsums are coming into bloom, and many other rare and curious plants are also included in the Belsize Court collection. Fruit trees in pots and in fruit houses, and vines have cropped heavily this season.

NOTICES OF BOOKS.

* COLOUR IN THE FLOWER GARDEN.

ANOTHER of Miss Gertrude Jekyll's charming books has just been brought out in the Country Life series by Messrs. George Newnes & Co. The book contains many suggestions as to methods of massing and grouping plants to produce striking and beautiful colour effects, a cult which is popular at the present time. We think it will occur to most of her readers that it is a matter of regret that a work which deals so largely with colour and colour effects should be devoid of any but black and white illustrations. Miss Jekyll is so well known as an expert in gardening from an artistic point of view that even those who differ from her in their ideals may well learn something from her book.

† THE NATURE BOOK.

THE first number of *The Nature Book* dealing with Nature study in many branches contains several articles and illustrations of a high order of merit. If one might choose a specially interesting illustration out of the many excellent ones in the book, the photograph of a sedge warbler feeding a young cuckoo commends itself to us as being a wonderful piece of work. Dr. Lockyer's account of the clouds will also form an attraction, as his article contains much that will be quite new to many of his readers. The book, as it is advertised to do, tells how to get a knowledge of the birds and animals of the fields and woods, the insects, the flowers, the trees, and other objects of the country.

PLANT NOTES.

THE BORONIAS.

AMONGST the few hard-wooded plants that are grown in large quantities for decorative purposes are the Boronias. There are several other species known, but only two or three are commonly in cultivation.

One of the best is *Boronia megastigma*, a slender-growing plant having delicately fringed blossoms. The growths need to be stopped freely during the earlier stages of the plant, for this induces a neat bushy habit. The small drooping, bell-shaped flowers are in colour chocolate out-side and yellowish within. In some specimens the flowers are unusually deep in colour, and this character is associated with plants of a compact habit of growth, but the deeper coloured flowers are not so fragrant as the paler tinted ones. *Boronia megastigma* is a native of South-west Australia, and was introduced in 1873.

Another species equally as popular as the preceding one, and far more showy when in bloom, is *Boronia heterophylla*, but the flowers lack the fragrance of those of *B. megastigma*. For the introduction of *B. heterophylla* we are indebted to the late Miss North, who sent the seeds to Kew, where the species first flowered in 1866. The plant is of rather upright growth, and when at its best condition every twig is densely packed with bright rosy-carmine bell-shaped blossoms. It is very necessary to shade the plants during the flowering period, otherwise the direct sunshine will cause the flowers to quickly fade.

A more vigorous grower than the two above-named is *Boronia elatior*, the shoots of which are freely clothed with rich green pinnate leaves. The partially drooping blossoms are urn-shaped and bright rosy-red in colour. It is largely cultivated in nurseries, and being later in blooming than either of the two described above, it forms a suitable subject for flowering in succession to them.

Another species now rarely seen, but which in the olden days used (with *Leschenaultia* and

† By Miss Gertrude Jekyll. Published by George Newnes & Co., Ltd., Southampton Street, W.C. Price 12s. 6d. net.

† Published by Cassell & Co., Ltd. Price 7d. net.

a few similar plants) to be regarded as a good test of the cultivator's skill, is *B. serrulata*. This in general appearance is widely removed from the others. The shoots have a low-spreading habit of growth, and they are clothed with curious trapeziform-shaped leaves, amongst which the bright rose-coloured flowers are produced in considerable numbers. The other species of *Boronia* are rarely seen save in botanic gardens.

GRAFTING ARALIA VEITCHII.

IN the *Gardeners' Chronicle* for June 20, Mr. T. Lunt advises the cutting down of any plants of *Aralia Veitchii* that have become too tall, in order to form effective bushy specimens. To this advice no exception can possibly be taken, yet at the same time it may be as well to point out that the pieces which have been cut off afford a ready means of propagating this *Aralia*. As young plants are always appreciated for table decoration and similar purposes a few additional specimens are sure to be useful. *Aralia Veitchii* is so difficult to strike from cuttings that for practical purposes this mode of increase need not be taken into consideration, but as a set-off it readily unites with the plant so long grown in gardens as *Aralia reticulata*, though I believe its correct name is now regarded as *Meryta Denhamii*. At all events the two must be nearly allied, as a quick and lasting union is the result. *Aralia reticulata* (for as such it is generally known) strikes very readily from cuttings, and the young plants are most useful when established in small pots. For grafting purposes the stem should be from the thickness of a straw to that of a small pencil, and in carrying out the operation the plants, which in most cases are furnished with leaves nearly to the base, may be cut back to a point at about 4 or 5 inches from the pot. If the tops are put in as cuttings they will supply stocks for grafting another year.

The best scions are furnished by the points of the shoots, but where a quantity is needed any plants that have grown too tall may be cut up into single eyes, each eye with its attendant leaf and piece of stem below it, thus forming a separate scion. If these are too stout to fit the stock care must be taken that one side fits exactly. What is known as side or veneer grafting is very suitable for the increase of this *Aralia*. The grafting should be done as low down as possible, and when the scions are tied securely in their places they must be removed to a close propagating case in the stove, and be kept carefully shaded. If so treated no grafting wax is necessary, so that the process of union may be seen. When the union is quite complete and the scions begin to grow, the remaining portion of the stock may be cut away, and the plants gradually inured to the ordinary atmosphere of the stove. They will then soon be ready to shift into larger pots, in the process of which the ball of earth should be sunk somewhat deeper than before in order to cover the point of union. Spring and early summer is the best time for carrying out this operation, but rather than waste the scions it may also be performed later. H.

THE POTENTIALIA.

THIS showy and hardy perennial is very useful for furnishing a supply of flowers during the months of May, June, July, and August. It may be readily increased by transplanting or potting divisions of the roots or side shoots in the spring just as growth has commenced. The plant is not particularly as to the situation or soil in which it is planted in, but a position fully exposed to the sun and a rich loam arc conditions calculated to produce the best possible results. The plants may also be propagated in August from seed sown in shallow boxes filled with light soil, covering the same lightly, giving water through a fine rose and placing the seed pans in a close frame. As soon as these are large enough to handle, prick the young plants

out 2 inches apart in boxes or in a warm border preparatory to being finally transplanted into their flowering positions. There are many fine named species and hybrids of the *Potentilla* in cultivation. Among the former may be mentioned the new and scarce *P. atrosanguinea*, which may be regarded as one of the very best and most beautiful of the numerous varieties in cultivation. The flowers are well formed, are of a fine brilliant scarlet colour, and are produced freely during the summer months. *P. cashmeriana alba*, *P. rosea grandiflora*, and *P. involucrata* are also excellent varieties for furnishing a supply of flowers. *H. W. W.*

weeks have reached the size of an egg, affording, in their colour and shape, a charming effect, and remaining on the plant till the end of September. During the period of growth weekly applications are needed of nitrate of soda or other nitrogenous manure. *F. M.*

CULTURAL MEMORANDA.

NERTERA DEPRESSA.

In order to obtain pretty plants of *Nertera depressa* well furnished with berries, the

months, well ventilated and moderately moist; and in the month of February afford more air and water. From the middle of the month of March till the middle of April place the plants on a warm bed, and quite near to the lights. During the flowering period the plants must be afforded abundant ventilation, applying water in the morning hours, so that the leaves may get dry as soon as possible, and in the application of water avoid wetting the flowers, as the less they are wetted the better they will set their fruits. When *Nerteras* are maintained warm and close during the flowering, the leaves smother the flowers and fruits, and the latter,

[Photograph by A. E. Smith.

FIG. 9.—ROSE LADY GODIVA, A SPORT FROM DOROTHY FERKINS: COLOUR OF FLOWERS FLESH PINK. (See p. 31.)

CUCURBITA OVIFERA.

This climbing annual plant is very interesting by reason of the similarity of its fruit to a hen's egg, and very suitable for clothing sunny arbours, verandahs, walls and balconies. The plant, under good cultivation, makes rapid growth, developing male and female blossoms at the beginning of the month of July in Italy, and in this country a few weeks later. The fruits set one day after flowering, and in three

following method of cultivation should be adopted. From the beginning of the month of August till the middle of September old stock plants may be divided, and the divisions potted in very sandy soil in large 60-sized pots, standing these in a garden frame in partial shade, and keeping them in a moist condition. In the winter bring the plants into the greenhouse and place them on a hanging shelf, as near to the glass as possible. Keep them, during the winter

owing to lack of sunlight, fail to colour. The chief points in the culture of the plants at this stage are to afford moisture regularly, plenty of air, and tolerably thick shading when the sun's rays are bright, in which manner the plants will show their fruits well above the leaves of the plant. When a good set of berries is secured, afford shade when the sun is brightest in the middle of the day, and syringe the plants late in the afternoon of hot days. *F.*

FLOWERS OF SPENSER.

(Continued from p. 8.)

CAMPHOR.

Had gathered Rue, and Savine, and the
flower
Of Camphora. *F.Q., III. ii. 49.*

Camphor is obtained from a tree of the Laurel family growing in China, Japan and Corea. It is quite certain that Spenser knew nothing of the tree, or he would not have spoken of the flower as used by the "aged nurse" to revive "the faire dunnell," for the drug is not derived from the flower but from the leaves and stems. But the drug was imported into England in the fourteenth century, and perhaps earlier.

CAPRIFOILE.

And Eglantine and Caprifole among.
F.Q., III. vi. 44.

Caprifole is the English form of the Latin *caprifolium*, i.e., the Honeysuckle.

CARNATIONS.

Bring Coronations and Sops in Wine.
Shepherd's Calendar, April, 138.

There is no doubt that Spenser's "Coronations" are what we now call Carnations, and his spelling helps us to the true derivation of the name from the use of the flower in garlands (*Corone*). (See also *Gillflowers and Pinks*.)

CEDAR.

1. The Cedar proud and tall. *F.Q., I. i. 8.*
2. No tree, that is of count, in greenwood
shape,
From lowest Juniper to Cedar tall.
F.Q., II. x. 22.
3. Which, like incense of precious Cedar tree,
With balme odours filld the ayre farre and
nie. *The Visions of Bellay, XI.*
4. High on a hill a goodly Cedar grewe,
Of wondrous length, and straight propor-
tion;
That farre abroad her daintie odours
threwe;
Amongst all the daughters of proud Libanon,
Her match in beaute was not any one.
World's Vanitie, 7.
5. The Phoenix left sweet Arabie;
And, on a Caedar in this coast,
Built up her tombe of spicerie.
An Elegie, 7.

It is very certain that Spenser never saw a living Cedar of Lebanon. It was not introduced into England till seventy years after his death, and he did not travel beyond Great Britain. But travellers from the East had confirmed all that was said in the Bible of the grandeur of the tree, and it was not only the typical example of all that was grandest among trees, but also the accepted emblem of all that was noblest in man. Trevisa (in 1398) described it as "the cedre is most hightre, lady and quene of all tren."

CHERRIES.

Queene Apples, and red Cherries from the
tree. *Mutabilitie, 43.*

CHEVISAUNCE.

The preue Pawnee,
And the Chevisaunce,
Shall match with the fayre flowre Delice.
Shepherd's Calendar, April, 143.

Spenser uses this word with two or more meanings. In the *F.Q.* (III. xi. 21) he speaks of "a noble chevisaunce," meaning a chivalrous enterprise; in the *Shepherd's Calendar* he speaks of a "wrong chevisaunce," meaning an undertaking or business; and in the passage quoted he evidently is speaking of a flower, which it is now impossible to identify. It is mentioned in 1620 by T. Robinson, but he was evidently copying from Spenser

CICUTA.

and Cicuta bad,
With which th' unjest Atheuans made to dy
Wise Socrates. *F.Q., II. vii. 52.*

Cicuta is the Hemlock, and there seems no reason why Spenser should have used the Latin instead of the English word which was in constant use; he was probably induced to do so because of the connection of the plant with Socrates.

CINNAMON.

The mouldie mosse, which thee accloseth,
My sinamon smell too much annoyeth.
Shepherd's Calendar, February.

The imported aromatic bark of the E. Indian *Cinnamonum Zeylanicum*, imported into England certainly early in the 15th century, and perhaps before that.

COCKLE.

Cockle for corn, and chaffe for barley, bare:
Shepherd's Calendar, December, 124.

Cockle is the accepted opposite of good wheat, its greatest enemy when growing and when harvested.

COLEWORTS.

Fat Coleworts. *Muioptomos, XVI.*

The general name for all plants of the Cabbage family.

COLOQUINTIDA.

Cold Coloquintida. *F.Q., II. vii. 52.*

Coloquintid or Colocynth is the fruit of a gourd grown in the South of Europe, and Northern Egypt, and in many other dry, warm regions. It was the proverbial emblem of bitterness, and so Iago speaks of the food that was once luscious becoming "bitter as coluquintida." It was the "wild yew" or "wild gourd" that caused the alarm "There is death in the pot," in *II. Kings, iv. 30*, and so it is translated in the Douay version "the colocynthides of the field," and in the Vulgate "colocynthides agri." It was known in Great Britain in the eleventh century, and perhaps earlier.

COLUMBINE.

Bring hether the Piacke and purple Cullam-
bine. *Shepherd's Calendar, April, 135.*

The name was applied to more than one flower in and before Spenser's time; but there is no doubt that in this passage he means the beautiful flower which we still so call. It is a true British plant, and is largely distributed throughout the Old World; and it has the peculiarity of bearing the names of two very different birds, the Eagle in *Aquilegia*, and the Dove in Columbine.

COLTWOOD.

All which she in an earthen Pot did poure,
And to the brim with Coltwood did it fill.
F.Q., III. ii. 49.

There is no known plant of the name of Coltwood; and it is probable that Spenser took the name from an earlier writer and copied it wrongly. Coltfoot naturally suggests itself, but it is not woody.

COSTMARY.

1. The purple Hyacinthe, and fresh Cost-
marye. *Virgils Gnat, 84.*
2. Fresh Costmarie, and breathfull Canomill.
Muioptomos, st. 25.

In both these passages Spenser joins the Costmary with other sweet-scented plants, but what plant he means by the name it is almost impossible to say. The Greek *Kostos* and the Latin *costum* are named but not described by Theophrastus, Horace and Pliny, and it is the rich ointment and not the plant from which it is made that they speak of. The ointment was very early imported into England from the East, and as an oint-

ment Spenser may have known of it, but only as a drug or spice is shown by its being associated in many European languages with the Blessed Virgin. *Costus* is still imported as a spice, but *Costmary* as a plant-name has long been obsolete.

COWSLIP.

Strew me the grounde with Daffadow-
dillies,
And Cowslips, and Kingcups, and loved
Lillies.
Shepherd's Calendar, April, 140.

The difference between Spenser and Shakespeare in the observation of our native flowers can scarcely be shown better than in their different accounts of the Cowslip. The flower must have been as well known to Spenser as to Shakespeare, yet this is the only place in which Spenser mentions it. Compare with this Shakespeare's description in *Henry V., The Tempest, Cymbeline*, and *A Midsummer Night's Dream*.

CUMMIN.

Ranke-smelling Rue, and Cummin good for
eyes. *Muioptomos, st. 24.*

Cummin is an annual North African herb, and the seed was imported from there into Europe from very early times. It was known for more than a thousand years, and has always retained its Greek name, which has doubtless been preserved from its Biblical associations. Isaiah, *lxviii., 27*, names the plant and says that "theitches are beaten out with a staff, and the cummin with a rod," and this is the way the seed is still beaten out in Malta. In Matthew, *xxiii.*, it is named as one of the titheable plants of the Pharisees. The plant resembles fennel, and is largely grown in Morocco and Malta, and the seed is imported into England, chiefly as an ingredient of curry.

CYPRESS.

1. The Aspine good for staves, the Cypress
funerall. *F.Q., I. i. 8.*
2. And aged limbs on Cypress stadle stout.
F.Q., I. vi. 14.
3. The great Earthes wombe they open to the
sky,
And with sad Cypress sadly it embrace.
F.Q., II. i. 60.
4. There mournful Cypress grew in greatest
store. *F.Q., II. vii. 52.*
5. And the sweet Cypress, sign of deadly
bale. *Virgils Gnat, 27.*
6. The Water Nymphs . . .
Now balefull boughs of Cypres doen ad-
vanche.
Shepherd's Calendar, November.
7. Sweet is the Cypress, but his rynd is
tough. *Amoretti, Sonnet xxvi.*
8. When as my hearse shall happen to your
sightes,
Vouchsafe to deck the same with Cypressae.
Daphnoidis, 488.
9. Instead of gyrlonde, weare sad Cypress
nowe. *Lay of Clorinda, 41.*

The Cypress among all writers has been the emblem of all that is sad and "baleful." As specially connected with funerals it was the "invisa cypressus" of Horace, and its graceful shape and rich evergreen colour did not make it acceptable to any but the gardeners of formal gardens. Its original home is India, from which it spread by Persia and Western Asia into Europe. There it found a congenial home, especially in the Transalpine parts, and from there it probably came to England, where it was largely grown long before Spenser's time; so that Turner, writing of it in 1548, says: "Cypresses growe in great plentie in My Lorde graces gardine at Syon" near the Thames.

(To be continued.)

THE ROSARY.

NEW WICHURAIANA OR RAMBLER ROSES.

Less than twelve years ago Wichuraiana Roses were little known in gardens, but probably because of their being lately known as

introductions that the evergreen habit is most pronounced. There are at the present time at least 30 distinct varieties which have been introduced during the past six or seven years, and all of which are of vigorous growth and produce flowers varying in colour from pure white to the deepest crimson.

are produced freely in loose sprays of usually four. The flowers, in their bud state, resemble in shape those of the well-known Tea Rose Homer, and are of a rich carmine shade, sometimes almost crimson, changing to a delightful rosy-pink, with the absence of purple, when expanded, and shading to a delicate peach towards the centre. The inner row of petals is slightly flaked with white.

It has proved very hardy and equally as rampant in growth and as free in flowering as Crimson Rambler, which, in habit, it resembles. The foliage is of a deep glossy green, leather-like in substance and almost evergreen. The flowers are very persistent, a valuable feature, especially in Roses overhanging gravel walks, lawns, &c.

Stella is another valuable addition to the Rambler section. In this variety the flowers are single, and are produced in immense trusses of a distinct pyramidal form, arranged in a regular manner and well beyond the foliage. A plant under observation is carrying no fewer than 19 trusses; the largest one contains 114 individual flowers. This large quantity of bloom is produced from a plant of a single stem not more than 5 feet high and grown in an 8-inch pot. The colour of the flower is a pretty shade of reddish-carmine, with an occasional splash of white on one of the petals: these are much enhanced by a conspicuous bunch of golden stamens in the centre.

The novel feature of this new introduction is its unique upright and rigid habit of growth, and its tendency to flower quite low down the shoots. The foliage is of a rich shining green colour, and is practically evergreen. The whole plant is devoid of any coarseness.

Paradise is a charming Wichuraiana Rose of rampant growth. The fragrant single flowers are produced freely in long sprays and in clusters of 20 to 30. In colour they are a delightful soft pink on the outer edge, gradually shading to a beautiful delicate rose towards the centre. They average 2½ inches in diameter, and are very distinct in form. The petals number five, and they have a peculiar curl. This variety embraces all the good qualities of a true Wichuraiana Rose, and when better known should become a general favourite.

Babette is a Wichuraiana Rose of free and sturdy growth: its habit is identical with that of Dorothy Perkins. The flowers are double, about 1½ inch in diameter, and of a very deep rose colour. They have a serious fault in not wholly unfolding their petals, which causes the flowers to have a peculiar buddled or withered appearance.

Delight is a grand acquisition, and a true Wichuraiana Rose of the highest type. The habit is very free in flowering and very rampant in growth. Its charming clusters of large single flowers, which are of a pleasing shade of deep rose, are produced in abundance. The individual flowers average 2 inches in diameter; these are white at their base. The flowers, especially when young, are of considerable beauty. *William Mallott.*

ROSES THAT MAY BE FORCED TWO AND THREE YEARS IN SUCCESSION.

THERE are several varieties of Roses which, owing to their strong growth and recuperative powers, can be forced with satisfactory results for two and three years. These are Frau Karl Druschki, Mme. Caroline Testout, Capt. Christy, and Baronne de Rothschild. Certainly the blooms are smaller the second year than the first; still they are quite presentable. The plants need, after flowering, a good soil and good cultivation in the open ground in pots plunged to the rim with a rich mulch afforded in the years they are forced. Before the first forcing the shoots should be cut back to from five to eight eyes, and when flowering is past the shoots should be cut back to dormant eyes and the plants repotted. *F. M.*

FIG. 10.—ROSE WHITE DOROTHY PERKINS.
(See p. 81.)

Evergreen Roses, they have become immensely popular during the last few years. This appellation was perhaps not thought of until extra vigorous growing kinds, such as "Dorothy Perkins," were introduced, and it is in these latest

Amongst the newer introductions, perhaps the most notable is Tausendschön (see Supplementary Illustration). This variety possesses very large semi-double flowers, often 3 inches in diameter when fully expanded. They

The Week's Work.

THE FLOWER GARDEN.

By W. FIFE, Gardener to Lady WASTAGE, Locking Park, Berkshire.

Kisses.—The plants now require daily attention in order to remove the old flowers and to combat insects, mildew and other pests. When mildew attacks Roses out-of-doors in dry weather, such as the case at the present time, on its first appearance flowers of sulphur should be dusted over the foliage in sufficient quantities to be plainly seen, allowing it to remain upon the plants for at least two days, when it is usually effective in preventing the spread of the fungus, but if by the agencies of wind or rain the sulphur should be removed in a shorter time, it will be necessary to make another application.

Shrubberies.—There is hardly a vacant spot at this season in the year in the pleasure grounds that would not look the better for the presence of a group of flowering shrubs, especially varieties of the improved strains be selected. *Campaula* medium (*Antbury Bell*) is very ornamental at the present time in many shades of colour. A good companion for the *Campaula* is the native *Valerian* officinalis, which flowers from June to August and has white flowers, also flowers of many shades of pink. The plant reproduces itself naturally from self-sown seeds from year to year.

Spiraea ariafolia.—This plant being intermixed with Delphiniums is very attractive, and, like most of the Spiræas when given the space to properly develop, gives a cool, moist rooting medium, the shade is needed well. Several other shrubby species of Spiræa flower during this month and August.

General work.—Give frequent attention to such operations as mowing, sweeping, rolling, watering, slipping the verges and hedges, pinching, pegging and training of shoots, stirring the surface soil with a hoe, and applying mulches where these are necessary.

FRUITS UNDER GLASS.

By T. COOMBE, Gardener to Lord LANGATTECK, The Hendre, Monmouthshire.

Melons.—Plants with fruits that are nearing maturity should be given a little more heat in order to develop the best flavour possible, and a moderately dry and more or less circulating atmosphere should be maintained during the night as well as in the day time. Until the fruits actually commence to ripen, the plants may be sprayed with water and the roots should be liberally supplied with moisture, but afterwards these operations must be discontinued and a drier atmosphere maintained. Plants on which the fruits are now swelling should have their secondary lateral shoots removed as they appear, the roots should be given a good top-dressing with a layer of turfy compost, and be adequately supplied with tepid water enriched with liquid manure or be top-dressed with a suitable artificial fertilizer of a soluble nature. Syringe the plants freely early in the morning, and again early in the afternoon when the house is closed for the day. Endeavour to maintain an atmospheric temperature throughout the night of 70° by closing the house early, but if this cannot be secured without the aid of artificial heat, it will be better to employ the minimum amount required. Continue to sow seeds for raising plants to fruit in the autumn, according to the demand that is likely to arise. If there are suitable structures for the purpose Melons of good quality may be obtained even during November.

Melons in frames.—The recent weather has been very favourable to these crops, and if there is a continuance of such weather the plants are not likely to be subject to canker. Should this disease, however, appear, let the affected parts be rubbed with dry lime and covered with powdered charcoal, which should never afterwards be moistened. In wet weather there is sometimes a difficulty in obtaining a good set of fruits in Melons growing in unheated frames. This difficulty, in a measure, may be overcome by raising the flowering laterals by and of wooden props towards the glass, thus keeping the blossoms and their pollen perfectly

dry. Thin out the laterals, and raise the fruits as soon as it is seen they have begun to swell, using small pieces of slate supported by flower pots. Slightly tilt the back of the lights early on sunny mornings and increase the amount of ventilation freely when the sun becomes stronger, but close the frames early enough in the afternoon to conserve plenty of sun heat, at the same time spraying the plants overhead with water.

Young Vines.—Plants which have been raised from eyes this year and were subsequently planted out will have made sufficient growth to have been stopped at about 6 feet in length. Keep the lateral growths beneath this point closely stopped after the first leaf, but the leading shoots should be allowed to extend and furnish the upper part of the trellis, as this will tend to encourage the roots to increase. Keep the borders properly mulched, and supply them with water as often as necessary, but no manurial assistance will be required this season.

Vines in pots.—Plants intended for fruiting next season have made considerable progress since they were finally potted into 12-inch pots. They require some slight manurial assistance, and should be supplied with tepid water when necessary. Stop the canes when they have reached a length of about 9 feet, and pinch the laterals and sub-laterals after the first leaf has been made. Keep the plants trained near to the glass, fully exposed to the sun, and syringe them freely at least twice each day. Ventilate the borders very carefully to prevent the leaves from being scalded. As soon as the canes commence to mature, increase the amount of ventilation. Leave the ventilator slightly open all night, and maintain the atmosphere somewhat drier, thus gradually preparing the plants for their removal to a position out-of-doors.

THE HARDY FRUIT GARDEN.

By F. JOHNS, Gardener to The DOWAGER LADY NEWBURNHAM, Warton Priory, Yorkshire.

Strawberries.—The work of raising young plants for the formation of fresh plantations should now be given attention. As soon as a sufficient number of good runners are procurable they should be layered, the best runners for the purpose being those upon young plants that have had their flower trusses removed. Runners taken early generally produce the finest and earliest crops of fruit. Fill a number of 3-inch pots with a moderately rich compost, placing a piece of rough loam at the bottom of each pot to act as material for drainage. Secure each runner in position in the pot by placing a stone over it. The young plants must not be allowed to suffer from lack of water at their roots. Land that has been deeply dug and heavily manured for early Peas, or early Potatoes, will be suitable for planting a few early strawberry plants. If such ground is not available, it will be necessary to liberally manure and thoroughly dig some land for the purpose, as a complete change of ground is necessary for each fresh plantation. Good varieties of Strawberries are plentiful, for a main crop Royal Sovereign, Leader, and Givon's Late Prolific can be relied upon. New varieties should be obtained for trial, as perhaps some variety will be found to succeed far better than any other in a certain locality. Bedford Champ is proving a robust grower and crops freely with us.

Raspberries.—The crop of this fruit promises to be a very one, and the canes will need to be mulched and frequent waterings of liquid manure. Remove any suckers that are not required for next season's fruiting, also prune out the weaker growths from autumn-fruiting varieties in order that light and air may circulate freely amongst the plants. Protect the fruits from birds by means of fish netting. Raspberries required for preserving should be gathered when dry.

The Loganberry and Blackberry.—Remove the weaker suckers from both these plants, retaining six or eight of the strongest growths for training to the trellis or poles according to the system of training adopted. Both the Loganberry and the Blackberry are cross-fertile, and they should be well mulched and liberally supplied with liquid manure during the period when the fruits are swelling, and especially is feeding

necessary in the case of plants growing in shallow and light soils. Remove the old fruiting canes as soon as the berries have been gathered, and treat the plants generally as in the case of Raspberries.

General work.—See that all ripening fruits are protected from the birds. Make a note of any trees that require root-pruning or assistance in the autumn in the shape of a top-dressing of rich compost. A visit should be paid early to some good nursery for the purpose of selecting any trees that will be required in the planting season; the early purchaser is likely to get the best trees.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Epsire, Hertfordshire.

Mushrooms.—Probably there is no more difficult season than during the next six weeks or two months for the production of fresh Mushrooms unless one is fortunate enough to possess cool cellars or caves where the temperature generally remains in a condition suitable to their growth all the year through. The next best site for their cultivation is at the foot of a north wall, where, by affording the bed a slight covering of long litter and damping twice daily, good crops may be assured. Further beds should be made up at intervals, either in the open or in any cool sheds facing to the north. The Mushroom house proper is seldom a good place for making up beds at the present season, but as opportunity presents itself clear out the old material in this house and make everything in readiness for receiving the prepared manure later in the year. Probably there is no more valuable ingredient by way of manure and lighting material for ordinary soils than manure from spent Mushroom beds, and therefore, every particle that is removed should be stored for use as required.

Autumn-sown Onions.—Immediately the bulbs have attained to a fair size, and before any signs of splitting can be observed, they should be lifted carefully and well harvested before placing them under cover. It is generally complained that these Onions will not keep well, but this is frequently because the crops are allowed to remain too long on the land before lifting. Such varieties as White Leviathan and White Emperor are generally cultivated for their good quality and earliness in maturing. These should be used first. The various forms of Rocca, however, although later, will keep quite sound and good till the spring-sown varieties are ready.

Maincrop Onions, which include all those sown at the commencement of the New Year, should be liberally watered both at the roots and overhead. If possible, this should be done in the evening. If the ground is well drained, one can hardly over-water the crops during such a spell of dry, hot weather as we are now experiencing, and it is quite impossible to cultivate such perfect Onions as are seen at the leading exhibitions, unless plenty of water be given. Well-diluted farmyard liquid should also be liberally applied.

Globe Artichokes.—The heads of these should be cut as soon as they have attained to a fair size. By placing the stalks in a little water, which should be changed occasionally, and standing the receptacles in a cellar or some similarly cool place, these will keep fresh and good for quite a fortnight. Keep the roots well supplied with moisture. An excellent stimulant is sewage water. If not already done, apply a mulch of long litter between the rows.

Cardoons.—These should be supported by placing a stout stake to each plant. Give a good mulching of short horse manure, and, if good specimens are expected, do not allow them to suffer for want of water.

Ridge Cucumbers.—So far the season has been an ideal one for these Cucumbers, and if the ground is well mulched, the growths kept clean from aphids, and plenty of water applied both to the roots and foliage, an abundant crop will result. Great care should be taken not to unduly tax the plants by allowing the fruits to remain after they have reached a fair size. Examine the plants daily, and cut all the fruits that are ready, placing them in water.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.
Moisture in the atmosphere and at the roots.—There is no more important operation connected with the cultivation of Orchids than that of supplying the proper amount of moisture. Therefore such work should never be entrusted to inexperienced or careless assistants. Even the most experienced cultivator needs to take every care in the discharge of duties connected with this matter; especially is this the case if he has a house containing a mixed collection of Orchids. I am sometimes asked how often and what quantity of moisture should plants of some particular genus receive, but it is impossible to answer such a question in a satisfactory man-

and what quantity of water is needed by any Orchid at any particular season. At the same time Orchids do not, as a rule, exhibit the ill-effects of careless treatment so soon as many other plants. But, although they may not appear to suffer at the time, sooner or later they will cease to thrive, and when this tendency is exhibited it is sometimes too late to arrest the deterioration. Plants that are now actively growing if allowed to suffer from dryness at the roots or in the atmosphere may not show any ill-effects at present, but they suffer injury none the less. It is just the same with over-watering. If the roots are treated to an excess of moisture many of them will be found at potting time to be decayed. The experienced cultivator will consider the atmospheric conditions prevailing

Insect pests.—Keep a sharp look-out for red spider, which attacks the under side of the leaves of many warm Orchids. Sponging of the leaves of dipping in some safe insecticide is the best remedy. The most troublesome of all Orchid pests are the black and yellow thrips, for if once these are allowed to become numerous they are exceedingly difficult to eradicate. Fumigation by means of one of the many nicotine vapourising compounds should be practised on their first appearance. Choose a calm night for the operation, and, as a preparation for this, no watering or overhead spraying should be done in the house during the same day, but the ventilators should be closed early, and the walls, floors and stages thoroughly damped. For a few days following the operation rather more shade should be employed than usual, as the foliage is more susceptible to injury from strong sunshine after its subjection to fumigation, or even after it has been dipped into some insecticide.

PLANTS UNDER GLASS.

By THOMAS LUST, Gardener to A. STREILING, Esq., Acra, Fife-shire, N.B.

Chrysanthemums.—The plants cultivated for producing large blooms are making extraordinary growth during the present month. They need frequent attention in the matter of supporting the shoots against the wind, but whilst taking care to tie the shoots sufficiently close to the stakes, it will be necessary to see that every tie is left loose enough to allow for the expanding of the shoot. All varieties have made their last "break" shoots, and these are fast developing. No more than three should be allowed to remain on at present, and in the case of the weaker growing varieties the third shoot will need to be removed later. During the present month and August, if the weather is very hot, and the plants are growing in a position where the pots are fully exposed to the sun, a board or plank should be placed on edge and laid against the sides of the pots, so as to shade them. The roots being now all around the inner sides of the pot they are apt to become burned if the pots are allowed to get very hot. For the same reason it is a good practice to damp the sides of the pot and soak the ground round about them with water two or three times each day. The plants should be syringed early in the morning, and again in the evening, and a little soot may be put into the water, just sufficient to colour it.

Euphorbia (Poinsettia) pulcherrima.—Plants that have been hardened off in 3-inch pots should now be shifted into pots 6 inches in diameter. The potting compost should consist of fibrous loam, leaf-mould and sand, adding a very little bonemeal and some manure from a spent Mushroom bed. The potting of these plants requires to be done very carefully, as the roots are very easily damaged, nevertheless the soil should be made moderately firm about the roots. Perfect drainage is necessary, as it is very detrimental if the excess of water cannot run freely from the pot. After the plants have been potted place them near to the glass in an unheated frame where the lights should be kept closed for a few days and shaded from bright sunshine. Spray the plants overhead twice each day in bright weather. When the roots have again become active, ventilate the frame freely, but only from the top of the frame, thus avoiding exposing the plants to a draught. A very little air may be admitted to the frame during the night. No shading will be required, but the plants should be induced to make as sturdy and short-jointed growths as possible. Turn each plant partly round every week.

Primula x Kewensis.—Seedlings which have been raised this season are forming nice plants, and should be potted into 6-inch pots, these latter being the pots in which they will flower. The potting compost should consist of good, heavy loam three parts, and leaf-soil and sand one part, adding a few small bones to this mixture. Ram the soil moderately firm around the sides of the pot, and place the plants afterwards on a base of ashes in an unheated frame situated in a cool position. This Primula is very subject to attack from green fly, which must be combated at every opportunity. Spray the plants with water, and treat them similar to *Primula* rather than *Primulas*.

[Photograph by A. E. Smith.

FIG. 11.—ROSE ELAINE, A NEW HYBRID TEA VARIETY; THE FLOWERS ARE WHITE OR PALE LEMON, TIPPED WITH PINK AND ROSE.

(See p. 31.)

ner, for if two species of the same genus are in full growth, one may need frequent syringings overhead, whilst the other would suffer injury if subjected to the same treatment. One species may succeed best if suspended from the roof rafters in a well-ventilated and sunny position, but the other may need the most shady and moist corner the house can afford. Again, the size of pot, character and quality of the rooting medium, length of time the plant has been potted, nature of the roots, and the vigour of the particular plants are all important details that must be given consideration in determining the amount of moisture necessary. It is by daily observation and long experience that a correct knowledge can be acquired of how often

out-of-doors before he commences to damp the surfaces in the house, or even to apply root waterings. If the weather is likely to be dull or wet, or if the atmospheric temperature in the house is not what it ought to be, no more watering or damping should be done than is absolutely necessary. If, on the contrary, the atmosphere is clear and the sun bright care must be taken that the moisture applied to the roots of the plants, or in the atmosphere is adequate to the needs of the plants. On such days a very early start should be made in the morning, both with regard to damping and overhead syringings, and the final damping for the day and the closing of the houses should be deferred for an hour or so later than usual.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of Plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unsolicited communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, etc., but no payment can be made for their use.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JULY 11—
Edgware and Little Stanmore Hort. Soc. Exhibition.
MONDAY, JULY 13—
United Hort. Ben. and Prov. Soc. Com. meet.
WEDNESDAY, JULY 15—
Hereford and W. of England Rose Sh. Women's Agric. and Hort. International and Exh. at Regent's Park, Woodbridge (Suffolk) Hort. Soc. Show.
SATURDAY, JULY 18—German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Five Years at Greenwich—63.9°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, July 8 (6 P.M.): Max. 71°; Min. 58°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, July 9 (10 A.M.): Bar. 29.8; Temp. 65°; Weather—Overcast.
PROVINCES.—Wednesday, July 8 (6 P.M.): Max. 62°; Min. 48°.
Chelmsford; Min. 54° Berwick.

SALES FOR THE ENSUING WEEK.

FRIDAY.—
Trees and plants in variety and specimen Japanese Dwarfed Trees and porcelain pots, at 07 & 88, Cheapside, L.C.C., by Protheroe & Morris, at 12.45.

The Origin of Species.

We have referred elsewhere to the remarkable gathering of naturalists held on July 1 to celebrate the Jubilee of the meeting of the Linnean Society, at which the epoch-making communications by Charles Darwin and Alfred Russel Wallace dealing with the problem of the origin of new species, were presented to the Society.

It is difficult for anyone who does not remember those stirring times to realise the immense difference that has come over our whole habit of thought and manner of contemplating our relation to the world around us, since that memorable meeting 50 years ago. Many of us can still recall the bitter controversies—often as unphilosophical as they were unscientific—which were waged around the central question, but it requires a strong effort of the imagination to realise that the majority of educated persons at that time seriously regarded each species as specially created, and as having existed since the world began.

Nobody at the present time thinks of species as immutable special creations. The question which now urges itself on the curious is not whether species were gradually evolved, but what are the processes which have produced the change, and what are the conditions under which they operate. We are restlessly endeavouring to unlock the secret methods of evolution, and have long since accepted the fact of evolution itself almost as a self-evident proposition—as an axiom of thought.

Like most great discoveries, however, that

which is associated with the names of Darwin and Wallace really neither began nor ended with them. The great merit of these pioneers lay in their having clearly recognised causes which were evidently competent to produce the requisite changes in living organisms, and to show that the actual conditions of life were such as to render the continuous operation of the causes themselves inevitable. Other biologists before them, notably Lamarck, had regarded a transformation of species as possible, and he conceived of it as resulting from the continuous effect of use or disuse of the various parts of the organism, whereby the useless became eliminated, whilst the specially useful parts or organs were capable of direct modification, and so became the more specially serviceable to the species, and further that this was due to the mere effect of use itself. Naturally, Lamarck's views encountered strong opposition, for there are vast masses of facts which are not explained by, if indeed they are not actually at variance with, such a hypothesis. It will be noticed that the capacity to vary on the part of the organism was assumed; the environment, or the particular habits of the individuals, were supposed to determine directly the nature of the change. A second assumption was also involved, namely that the characters so acquired during the life of an animal or plant were also inheritable.

The great merit of the work of Wallace, and especially of Darwin, was to show that, as a matter of fact, variation did actually occur, and far more extensively than was at that time realised; that out of an enormously numerous progeny at each generation only very few survived, and these were supposed to be chosen as being in some way specially fitted beyond their fellows for their surroundings. This idea is embodied in the phrase "survival of the fittest," though the process might perhaps be more correctly described as the "elimination of the worst."

The details of the theory have proved, as is so often the case, not to be so simple as they once appeared, but this in no way detracts from the brilliance of the doctrine itself as advocated by the great English naturalists, nor does it lessen our admiration for the wonderful ability with which the available facts were marshalled, so as to carry conviction to the mind of almost everyone who was qualified to form an independent judgment on the matter.

Considerable divergence of opinion arose as to how far the alleged factors of use and disuse can rightly be held accountable for that kind of change in the organic world which is described by the term evolution. We have already alluded to the weight attached to them by Lamarck, and Darwin himself attributed greater importance to their effects in his later years than he did at first. But, on the whole, the weight of opinion has told against them as immediate causes of change. They have, moreover, become intimately bound up with the supposed inheritance of acquired characters, concerning which there exists a considerable literature—much of it based on a misapprehension as to what is really meant by writers who deny that such characters are transmissible. Perhaps the clearest exposition of the subject was given by Weismann, who analysed the

confused meanings that lurked in the term, and showed that the difficulties in the way of its adoption, when its meaning is properly understood, are well high insuperable from the point of view of facts, and no less so from that of theory.

Of course, no one denies that plants and animals may be, and often are, obviously affected by their environment, and this in a very definite manner; the whole history of cultivated plants proves it up to the hilt. But, in the first place, it must be remembered that cultivated plants are selected for cultivation just because they already possess the capacity of responding in a particular way to certain forms of treatment. And in the second place, we know, in many plants at any rate, the effects of cultivation are cumulative over several generations. The real question, however, as to the inheritance of acquired character goes a good deal more deeply than this, and, indeed, is not to be decided by such a criterion at all. It can only be settled by testing whether the modifications which have thus been produced are the expression of a genuine change in the organism itself, or whether they merely represent what we may term the somatic response, as opposed to a constitutional alteration. It is not a little remarkable that cultivated vegetables should have been appealed to for support by the protagonists on either side. Perhaps neither side is perfectly clear from reproach, for facts in untrained hands are apt to be as ineffective as are the most subtle speculations which fail to take cognisance of them. It is, perhaps, not always clearly recognised that the nutrition of the seed or the intramaternal development of an animal embryo, will materially influence its subsequent history, for it produces its effect at the most critical period of development.

It appears, however, that limits are soon reached, beyond which no further improvement is attainable by the direct action of the environment; or, at any rate, if any change should become apparent, its occurrence is so capricious that it is evident that some other factors, besides those of the environment, are really responsible for its manifestation.

And thus the way is further opened for experimental treatment of the problems. We are at present in the midst of the experimental stage, which had already been inaugurated by Mendel, in 1865; but the world was not then ready for his results, and they lay for many years unnoticed, till the fruitful field which Darwin had opened out had become more fully explored, its possibilities grasped and its limitations felt. Then, almost simultaneously, De Vries, Correns, and Tschermak, all working independently, found they were pursuing a line of investigation which had already been followed by Mendel with those remarkable results that are now within the knowledge of all who are interested in these problems.

The essential feature of this modern work consists in the carrying out of carefully-planned experiments in breeding, which will admit of analysis of the various factors which make up the final result. Already the principles which underlie cross-breeding are becoming elucidated, although much remains to be done in this direction. The recognition of the so-called "elementary species" of cereals

and other plants, and the utilisation of this knowledge in connection with the scientific experience obtained from the study of hybrids and their descendants is already yielding results, the value of which can hardly be overestimated. But the whole of that important modern branch of science to which Professor Bateson has given the appropriate name Genetics forms the natural outcome of that conception of the origin of new species which we owe to the great founders of the modern doctrine of evolution.

OUR ROSE PICTURES.—Our Supplementary illustration is from a sketch, by Mr. WORTHINGTON SMITH, of the beautiful Rose Tansendeschon, that was exhibited in many groups at the National Rose Society's exhibition on Friday, 3rd inst. Since varieties such as Lady Gay, Dorothy Perkins, and Pink Pearl have given such popularity to climbing varieties of Roses, rosarians have devoted their attention largely to raising new pillar Roses, and the subject of our sketch may rank amongst the finest of these newer introductions. The variety is of German origin. The flowers are large for Roses of the multiflora section, that shown in our picture being natural size. The petals are a beautiful shade of pink, which develops a carmine tint as they expand. The trusses of blooms hang in large clusters. The shoots are almost thornless, and the foliage is large and handsome. This variety was given an Award of Merit by the Floral Committee of the Royal Horticultural Society at the recent Temple Flower Show, and on the same occasion this distinction was also granted to the varieties Elaine and White Dorothy Perkins. A description of these Roses is given in our report of the Temple Show, p. 338, in the last volume. Another pretty variety is seen in Mr. MASON GOOD'S photograph, where Blush Rambler (see fig. 14) has covered a rustic arch and is flowering in profusion. Dorothy Perkins Rose is a great favourite, and it has given rise to a sport in which the flowers are soft flesh-pink. It is known as Lady Godiva (see fig. 9), and a plant shown by Messrs. PAUL & SON, Chesnut, attracted much attention at the recent Temple Show.

BOTANICAL MAGAZINE.—The issue for July contains figures and descriptions of the following plants:—

BEGONIA CATHAYANA, tab. 8202.—This plant is closely allied to *B. Bowringiana* (figured in *Gardeners' Chronicle*, vol. xxxiii, 1903) and *B. laciniata*, two plants that have been regarded by DE CANDOLLE and others as varieties of one species, though Mr. HEIMSLY looks on them as unquestionably distinct. *B. cathayana* was introduced into cultivation by Mr. A. K. BULLY by means of seed sent by Dr. HENRY. It is a handsome stove plant, and responds well to good treatment.

CELEGYNE PERAKENSIS, tab. 8203, has been confused with *C. sulphurea*, from which it differs in the larger pseudo-bulbs and the longer sheaths and bracts of the inflorescence.

DIDYMOCARPUS CYANEA, tab. 8204.—This species was collected in the Siamese part of the Malay Peninsula by Mr. C. CURTIS, late of the Penang Botanic Gardens. It is a decorative plant, flowering in the autumn in the tropical house, and it requires the same kind of treatment as does *Streptocarpus*.

OLEARIA RAMULOSA, VAR. *COMMUNIS*, tab. 8205.—This is one of the most beautiful of the *Olearias*, and, like the rest of the species of this genus, is entirely Australasian. It forms a shrub 3 to 6 feet high, with linear-lanceolate

leaves, and bears white, Aster-like flowers in spring. It succeeds in the open against a wall in favoured localities.

RHODODENDRON MARIESI, tab. 8206.—This *Rhododendron* was raised from seed received by Kew from Dr. HENRY, who collected it at Ichang. It is one of the, comparatively speaking, low-level species occurring below 4,000 feet in Central China. It forms a shrub 3 to 6 feet high, and is a handsome spring-flowering plant, which should succeed well in the warmer parts of the British Isles.

LARCH AS AN AVENUE TREE.—Rarely, if ever, has any species of Larch been employed for street planting in this country, but at Bad Landeck, in Silesia, there is such planting to be seen. The trees have a peculiar form, not erect and slender as is the case with Conifers in general, even when headed back, but with crowns like other species of trees. It was supposed that pruning had something to do with the peculiar forms of the trees, but experiments made with young Larches proved that that was not the case. It was thought that bending down of the branches under snowfalls was a cause, but experiments showed that this was not so. The trees date from the year 1750, and are worthy of all care in their preservation.

PROFESSOR DR. FRITZ NOLL.—This eminent plant physiologist, Director of the Botanical Institute at the University of Halle, died suddenly in his 50th year on June 20 last. Dr. NOLL was for many years professor at the Agricultural Academy, Poppelsdorf, and at the University of Bonn. It was only so recently as last year that he was called to Halle. He was well known as one of the joint authors of the *Bonn Textbook* of botany, which is deservedly well known in this country, and he has also published a number of valuable original papers on botanical subjects.

FLOWER PICTURES AT THE PARIS SALON.—The flower pictures in the Salon are inferior in point of number to those exhibited at the spring show of the National Horticultural Society of France. The leading French Horticultural Society has for some time past allotted a certain amount of space to artistic productions, and at the recent spring show a gallery comprising 425 pictures in oil and water colours, mostly of fruit and flowers, formed one of the conspicuous attractions of the exhibition. Although this show is open for a week only, it is said that many artists who make a speciality of fruit and flowers prefer to send their pictures to the Horticultural Society's show for that brief period rather than send them to the Salon. At any rate there was a charming display of very beautiful works of art on view at the far end of the greenhouses, and a special catalogue had been prepared for the use of such of the visitors as were interested in them. The Grand Palais des Beaux Arts, where the Salon is held, contains about 100 pictures of floral interest, and one of the first to arrest our attention was a three-quarter length, life-sized portrait of M. ABEL CHATENAY. Most of the others are representations of popular flowers and garden scenes.

"LA REVUE CHRYSANTHEMISTE."—This new publication has now reached its seventh number and appears regularly on the first of every month. It maintains its style in every respect, and contains much matter of interest to admirers of the Chrysanthemum. The issue for July contains articles on Chrysanthemum sports, advice to small amateurs, short notes, bibliographical notes on the varieties originally introduced into Europe, and culture for large blooms.

EXHIBITION AT TURIN.—An international industrial exhibition is being organised in Turin, and will be held there in 1911 to celebrate the fiftieth anniversary of the proclamation of the Kingdom of Italy. In connection with the exhibition three flower shows will be held. The first will take place in May, and will include garden decorative plants, greenhouse plants, cut flowers and floral compositions, market garden produce, fruit, and colonial plants and products. The second show will be held in September. Classes are provided for ornamental garden plants, greenhouse plants, and market garden produce. The third show, which will take place towards the end of October, will be for fruit, vegetables, and kitchen garden produce, flowering plants, ornamental plants for apartments, and cut flowers.

BOTANIC GARDEN FOR BRITISH HONDURAS.

—About eighteen months ago the site for a new botanic station in British Honduras was selected, and the work of clearing and laying out was at once started. The area of the new station is about 20 acres, and is conveniently situated near to Belize. The Government of the colony has now decided that the station shall be a permanent one, and lately voted the sum of \$2,980 for its upkeep during the present year. A further sum of \$1,400 was also voted for building quarters for the superintendent.

BERLIN.—We learn from MÖLLER'S *Deutsche Gärtners-Zeitung* that the great Palm-house in the old Botanical Garden has been pulled down, nothing remaining but the Museum of Botany in the Grünewaldter Str.

FEDERATION OF HORTICULTURAL SOCIETIES IN HOLLAND.

—At Utrecht, on May 14 last, a meeting was held at which all the principal horticultural societies of the Netherlands were represented, and the Netherlands Horticultural Federation was founded. Forty-nine societies, representing the different branches of horticulture, and embracing nearly 18,000 members, have already joined the federation. In future this federation will form the central representation of Dutch horticulture.

INTERNATIONAL RUBBER & ALLIED TRADES EXHIBITION.

—An exhibition of this nature will be held at Olympia in September next. Messrs. J. A. ALEXANDER and A. WHYTE, 75, Chancery Lane, London, inform us that they have undertaken to collect and arrange for the botanic section all the economic tropical plants, so that they may be grouped in their orders; also, more particularly, all lactic plants, whether the produce be of a commercial value or not. Groups of other tropical plants than the above specified will be accepted.

EFFECTS OF FROST IN FRANCE.—The frosts which occurred in April last have done considerable damage in the French orchards. According to M. CHALET, secretary to the Pomological Society of France, the Pears *Beurré Hardy*, *Duchesse d'Angoulême*, *Figure d'Alençon*, *Beurré Diel*, *Beurré Gris*, &c., have been badly hit, whilst *Beurré Clairgeau*, *Triomphe de Vienne*, and *Marguerite Marillat* have practically escaped, though growing alongside those that were injured. In spite of the frost, the blossoms appeared to be luxuriant; they failed, however, to set fruit, and examination showed that the stamens and styles were blackened, and thus rendered functionless.

Publications Received.—The Perfect Garden:

How to Keep it Beautiful and Fruitful, by Walter F. Wright. (London: Grant Richards, 7, Carlton Street, S.W.) Price 6s. net.—*Country Sketches for City Dwellers*, painted and described by Mrs. Williamson Rawnsley. (London: A. & C. Black.) Price 7s. 6d.

ONCOCYCLUS IRISES AND COLD STORAGE.

—The note by Mr. W. R. Dyles, on p. 536, detailing the experiment he has in progress in submitting the rhizomes of these Irises to cold storage treatment in the hope of mitigating the frozen condition under which some of the species are found in their native home is interesting. What I anticipate will happen is that a loss of stature will result in the flowers; while the shorter period of time between the planting and flowering seasons will be largely responsible for an enfeebled development of rhizome. A chief point of difference in the cold storage treatment and the frozen soil conditions of nature is that in the former state the plant's growing powers are held in check while the plant remains in the dry state, while the mature plant has rooted probably to its fullest extent—especially as concerns its main or basal roots as opposed to the lateral or fibrous roots that appear in spring time usually—and is, therefore, in a far better condition to follow up the functions of leaf growth when the climatic conditions permit of this being done. I take it Mr. Dyles has been experimenting with the collected rhizomes of these Irises, and I hope, at some future time, he will further inform us as to the results and the names of the kinds he has submitted to such a test. My experience of the *Onocyclus* group does not fully bear out the statement by Mr. Dyles that "whether the rhizomes are in or out of the ground they begin to develop shoots in October." I have frequently recommended the planting of these Irises late in November or even in December, with the express object of keeping the shoots below the ground till the worst of our winter comes. I would particularly like to know later on the effect of the cold storage on the development of the rhizome to carry on the flowering another year. E. H. Jenkins, Hampton Hill.

—**"THE WARLIKE BEECH."**—Canon Ellacombe in his instructive notes on the "Flowers of Spenser," says he cannot explain this epithet. It probably refers to the smooth surface and steel-grey colour of the bark of the beech, which is like in appearance to plate armour. It is very noticeable in groves of trees not too advanced in age. Each "warlike" trunk—with a little imagination—appears to be clad in steel armour. W. G. S.

—**STRAWBERRIES.**—This is the best Strawberry season at Lockinge during the past 16 years, the quantity and quality of the fruit easily surpassing anything during that time. This would not have been the case had it not been for the fall of snow in the last week in April, which protected the plants when we registered 14° of frost. With the exception of Royal Sovereign and the old variety Keen's Seedling, Strawberries refuse to grow freely in this immediate neighbourhood. There are, however, two additional varieties that are likely to suit this soil. The first is Bedford Champion, a great cropper, with fine, round fruits of deep scarlet colour and firm flesh, well suited for travelling. Latest of All is in flower when the others are ripe, and is well suited to this soil. W. Fyfe, Lockinge Gardens, Wantage.

—**THE WINTER MOTH CATERPILLAR.**—Many and grievous are the reports heard of the depredations of this caterpillar amongst Apple orchards this season. It seems to matter not that the life history of this Apple tree pest is so well known, that methods of checking its depredations have been so widely published, and that destructive agencies are available; in respect to the largest Apple areas, we seem no farther advanced than we were 30 or 40 years ago. I will remember the terrible havoc wrought in those days in the Middlesex orchards, the trees being entirely denuded of leaves, whilst growers looked on helplessly, evidently ignorant of any ameliorative agencies—certainly no one need be ignorant now of the means available. Coming back by the London and South Western Railway from Wimbor the other day, I passed a large orchard of fruit trees which have been planted some 12 to 14 years. Many of these bore evidence of the presence of the caterpillar, being largely defoliated. But the ground, which had been planted with bulbs or Wall-

flowers, was covered with grass and weeds, which offer cover to the larvae, and rendered impossible any systematic effort to destroy the pest. I wonder how far the surface condition of that orchard compared with that of orchards in those parts of the country where the caterpillar has been most destructive, in spite of caustic soda and other solutions that have been sprayed over the trees in the winter. Do these solutions really destroy the eggs of the winter moth when once they have been deposited on the tree, branches and stems. That is a question which it may be worth while answering. Are these sprays as efficacious to check the operations of the moth as are proper grease bandings to the stems, if these latter are applied early and given proper attention afterwards? Would not the sprays be more effective if applied earlier in the winter, when the moths are presumably depositing their eggs on the trees. If the eggs are immune from the effects of spraying, are also the insects? Without doubt the moths are most active during genial weather in November and December, and it is just at that time when the surface soil should not only be clear of all vegetation, but be forked up to expose the larvae to fowls and birds. Having regard to the value as protection of the grease bands, all trees should have clean, single stems fully 18 to 24 inches above the ground to enable these bands to be properly applied. When three or four stout branches start close to the ground this form of protection is hardly available. D.

—**TRIALS AT WISLEY GARDENS.**—There is being conducted some interesting experiments with edible Peas treated with the nitro-bacterial preparation and other solutions that will command the active attention of the Scientific Committee and Pea growers in general. There is also a trial of 96 assumed diverse Potato stocks, as also one of 17 lots of the variety Up-to-Date, the seed tubers coming from different sources. This should form an interesting growth trial.

—The breadth of Potatoes on the whole looks good. Then there is a trial of 47 diverse stocks of Peas, 36 lots of Parsley in twin rows; there are 114 rows of Beets, all doing well, and some 90 sorts in twin rows of spring town Cabbages. There are numerous stocks of Long Pod Beans and Runner Beans. Several varieties of Asparagus in rows are growing from seed. A big breadth of Brussels Sprouts has yet to be got out, and probably other things also. Of fruit, Strawberries have been largely extended, and a large number of layers are to be got into pots shortly for a pot forcing trial next spring. The Laxton was doing splendidly in the sandy soil. On the higher ground there is being conducted a singularly interesting trial of vines, to be ultimately trained horizontally against trellises. They have been planted in order to test the suitability of the Wisley soil and the climate to produce vine-making Grapes. Next there is a very extensive collection of gooseberry bushes, each variety represented by two plants. Pyramid Pears are in great numbers, and all are healthy. In the span vineries there is indeed a surprise for the pessimistic critic who last autumn foretold bad breaking on the part of the new and very stout rods on the young vines. There has not been a bad break amongst the whole lot; indeed, a better development of lateral growths or promise of a finer crop of bunches could not be seen on any vines in the kingdom. A limited lot of Melons are being grown in a low-span house, but these do not constitute a perfect trial. Roses, especially the climbing varieties, are in luxuriant growth and in glorious bloom. Peonies have been a grand sight. Those who failed to see the Japanese Primulas a week or two since lost a very beautiful spectacle. A. D.

Obituary.

—**BENJAMIN GREAVES.**—This gardener died at Horsham on the 5th inst. The late Mr. Greaves, a Yorkshireman by birth, was head gardener at Brooms Hall, Surrey, for 40 years—30 years with E. Pennington, Esq., M.P., and 10 years with Sir Alexander Brown, M.P. Many years ago Mr. Greaves was one of the foremost gardeners of the district. He retired about four years ago.

—**ALEXANDER WALLACE.**—We regret to learn of the death of Mr. Alexander Wallace, Editor of *The Florist's Exchange*, of New York and Chicago. Mr. Wallace was born in Lawrenceville, Kentucky, in 1839, and emigrated to America many years ago. His loss will be severely felt in horticultural circles in America.

—**CHARLES PENFORD.**—On the 2nd inst., at his residence, Mr. Charles Penford passed away, after a long illness. Deceased was well known to Chrysanthemum growers, exhibitors, and raisers. As a raiser of seedling Chrysanthemum he obtained gratifying success, and there are many of his excellent varieties still much appreciated. Such varieties as Mrs. Norman Davis, Sydney Penford, Leigh Park Wonder, and Joseph Stoney may be mentioned as some of his latest achievements, while there are numerous others of earlier origin which still hold their own on the exhibition board, among which may be named the beautiful Duchess of Sutherland, Beauty of Leigh, and Florence Penford. Mr. Penford was for many years a successful exhibitor, especially at the "incurred" varieties which were more popularly esteemed than those at present. For more than 30 years he held the position of head gardener at Leigh Park, Havant. Deceased was 74 years of age.

—**GEORGE SALTER.**—The recent death of this old florist, from senile decay, has been recorded in *Jackson's Journal*. Deceased was a boot-maker, and had a shop in the lower part of St. Albans's Street. He was one of the enthusiastic florists who in the middle of last century cultivated and exhibited such flowers as Pansies, Pinks, Auriculas, and Polyanthus. He is stated to have been one of the founders of the National Chrysanthemum Society in 1863. Deceased leaves a son and two daughters.

—**THOMAS HOGG.**—In the death of this gentleman, which took place at Crookston, near Paisley, on June 20, one of the ablest gardeners in the West of Scotland has passed away. As a young man he served under some of the best gardeners of the time. He was subsequently appointed head gardener to Mr. Todd (now of Eastwood Park, Giffnock, N.B.), at his residence at Partick, a site long since built over. At this place there was cultivated one of the finest collections of stove and greenhouse plants to be found in Western Scotland, and under the skillful care of Mr. Hogg these plants were always regarded as object lessons in cultivation. After the lapse of some years he was appointed gardener to the late John Gordon, at Aitkenhead, Cathcart, near Glasgow. From this place he exhibited very frequently at the competitive exhibitions, showing all sorts of plants from the regal *Elargium* to Orchids. Such excellent cultivation did these plants demonstrate that the name Hogg, of Aitkenhead, became a household word in gardening circles throughout Scotland. Show Dahlias and vegetables also claimed his attention, and many a struggle took place between him and the late Mr. McBean, of Craigends, with vegetables. These two gardeners were the foremost cultivators and exhibitors of vegetables in Scotland. At all the important exhibitions in Scotland Mr. Hogg's services as a judge were sought and appreciated. In August, 1859, he became gardener to A. Coates, Esq., Woodside, Paisley, where he remained until about two years ago, when failing health compelled him to sever practical connection with the profession he loved so well. In his later days deceased used to say that, were he again a youth, he should choose gardening as his profession, but would try to become a better exponent of the art. A student of classical and scientific literature, and a close observer of nature, his mind was well charged with knowledge, which he was ever ready to impart to others. Possessed of a somewhat brusque temperament, straightforward, and candid to a fault, he had a kindly disposition, and in his upright and professional zeal set an example to his pupils which cannot be easily effaced, this being especially true in my own case. Deceased leaves a widow and grown-up family, for whom every sympathy is felt. One son, named after his father, is well known in the Border counties and in Scotland as the representative of Messrs. A. Cross and Son, Glasgow. J. F. McCleod

Royal Horticultural Society.

Summer Exhibition at Holland House.

JULY 7, 8.—On these dates the park at Holland House, Kensington, was once again placed at the disposal of the Royal Horticultural Society for the holding of the summer show, which has come to be regarded as an annual event.

Despite what has been said and written in regard to previous displays at Kensington, we have no hesitation in saying that the exhibition held during the present week was in most respects superior to any preceding show. Exhibitors have become more used to this fixture, and it is evident that they make preparations for it in much the same manner as for the Temple Show, the result being that, as was the case in the earlier history of the Temple displays, the shows at Holland House appear more and more to consist of carefully-selected exhibits, the difference in the general quality on Tuesday last, as compared with that observed at the first exhibition, being very marked.

In some respects the summer show was more interesting than that held in the Temple Gardens, for there was a better display of fruit (including a collection of Linapples) and an excellent exhibit of vegetables.

There were fewer Orchids shown than was the case in May last, and this is natural on account of the season; especially was this the case in respect to exhibits from amateurs. Nevertheless, there were some excellent groups from members of the trade, and several novelties were selected for Awards by the ORCHID COMMITTEE.

There are always some magnificent group exhibits at this show, and on the most recent occasion those arranged by Mr. AMOS PERRY and Messrs. WALLACE & Co. excited much admiration.

Mr. PERRY'S water gardens and Nymphæas extended for the greater part of the length of one of the tents, and at either end were flanked by groups of choice Delphiniums that continued the exhibit to the boundary. Messrs. WALLACE'S exhibit at the entrance to the largest tent was a small one, but it evidenced an appreciation of the artistic that was distinctly commendable. It was a reproduction of a scene in a Japanese garden, copied from a picture, and the groups of Japanese Irides were exceedingly effective. Further groups of miscellaneous plants and flowers from Messrs. R. & G. CUTHBERT, Messrs. JAMES VEITCH & SONS, LTD., Messrs. H. B. MAY & SONS, Messrs. FRANK CANT & CO., Mr. A. F. DUTTON, and the two firms of Paul are worthy of high commendation.

Among the Awards of Merit granted by the FLORAL COMMITTEE, it is worthy of remark that four were given to new Roses of great merit exhibited by Messrs. ALEX. DICKSON & SONS.

At 1 p.m. the Society's committees were entertained at luncheon, the President, Sir Trevor Lawrence, presiding. Speeches were made by the President, and by Sir Albert Rollit, and Messrs. W. Pompart, T. Challis, and J. Cheal. The opportunity was thus afforded of publicly thanking Mary Countess of Ilchester for her kindness in lending the ground.

The weather on the opening day was glorious, and there was a very satisfactory attendance, but on Wednesday the skies were dull, and rain fell during the greater part of the day.

The arrangements made by the secretaries and Society's officials were frequently the subject of appreciative remarks.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. Chas. Blick, W. Howe, C. R. Fielder, W. Bain, J. F. McLeod, Chas. Dixon, T. W. Turner, W. P. Thompson, James Douglas, W. J. James, W. G. Baker, Jno. Green, G. Reuthe, J. W. Barr, Herbert J. Cuthbush, H. J. Jones, and R. Hooper Pearson.

GROUPS OF PLANTS.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, showed one of their fine groups

of stove and greenhouse plants, it being difficult to know which most to appraise, the quality of the plants or the method of their staging. The foliage plants were at their best condition, and they included Anthurium crystallinum, Dracæna Doucetta de Grooté, D. Goldiana, Croton Hawkeri, Caladiums in variety, and a host of other beautiful plants. On tall stands were Nepenthes N. Amesiana, and N. tuba having exceptionally fine pitchers. A few subjects in flower gave additional colour to the group.

Messrs. SANDER & SONS, St. Albans, showed a group of their new plants such as were shown at the Ghent Exhibition, several of which were illustrated in the issue containing the report of that show and the preceding number. (Croton Fred Sander, Furcraea Watsoniana, Pereskia Godseffiana, Sansiviera Laurentii, Pycnopharyx Sutherlandii, and others upheld the good opinions which were bestowed upon them earlier in the season.)

Messrs. W. BULL & SONS, King's Road, Chelsea, showed a group of foliage plants of stove and greenhouse species, perhaps a little too green in appearance for the best effect, but a choice specimen of Heliconia illustris, bright Dracænas, Codiaëus (Crotons), and Caladiums made some amends in this respect. At either end of the exhibit were excellent plants of Dracæna Victoria.

Mr. L. R. RUSSELL, Richmond Nurseries, Surrey, staged a handsome bank of exotic plants of ornamental-leaved species, well arranged in a corner of the largest tent. Dracænas Codiaëus (Crotons), Caladiums, of which many handsome plants were seen; Aralias, and similar plants with Ferns, Palms, Bamboos, &c., made a very fine exhibit.

Messrs. H. CANNELL & SONS, Swanley, Kent, staged a semi-circular group of Cannas in a setting of Adiantum Ferns and edged with flowers of Lilium candidum and plants of Isolepis gracilis. The Cannas were of exceptionally fine quality; the selection was large, there being no fewer than 150 plants in about 100 distinct varieties. Amongst novelties may be mentioned Amelie Weibel (salmon-rose), Flossie Bonheur (very soft yellow), H. von Otrante (deep yellow with red lip), Venus, a variety with broad petals; the star of Baroda, the deepest spotted Canna, the markings being bright red, and A. Mayes, large flowers of richest gold colour. Messrs. CANNELL also showed in another tent plants of Fuchsia Henkel—a variety of the Corymbiflora type with sepals, petals and tube of an orange red tint—most floriferous. The variety of Fuchsia Mary has a similar habit of growth, but the flower is smaller, and of a brilliant scarlet tint; F. Perle is of a salmon-pink tint.

A striking group of flowering plants was put up by Messrs. R. & G. CUTHBERT, Southgate, Middlesex. A host of flowering subjects with Ferns and other foliage plants and tall pillar Roses, Humea elegans and Lilium for relief, produced a fine effect. The groundwork was formed of Spiræas of the pink varieties, Pelargoniums, dwarf Roses, Callas, Statice Saworwood and Lilium longiflorum. The pillar Roses embraced such floriferous kinds as Lady Gay, Cant's Bush, Dorothy Perkins, Hiawatha, Madame Levassour and others.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, showed Carnations, Roses, Hydrangeas, Ericas, the white Nerium Oleander, Bougainvillea spectabilis, with variegated foliage, also a group of foliage plants, sprays of ornamental trees and shrubs, fruiting Fig trees in pots, Metrosideros floribunda and other subjects. The exhibit of Carnations was especially fine, and included blooms of most of the types of this popular flower. Souvenir de la Malmaison varieties were especially good, the beautiful Princess of Wales variety being prominent in epergnes. At the back were great bouquets of such choice kinds as Britannia, Lady Bonfield, White Perfection, Mrs. H. Burnett, & a new yellow variety of the Souvenir de la Malmaison type labelled C. P. Little is of much merit.

Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, showed a group of Ferns, some of them very large specimens, the whole occupying an area of 500 square feet. In the centre was a fine plant of Nephrolepis exaltata superba; other notable specimens were Gymnogramma schizophylla superba, Nephrolepis exaltata Amemphii (a handsome variety of this elegant Fern), Asplenium nidus madagascarense, Davallia solida superba, a great clump of Platycerium alcicornine, Polypodium conjugatum, Drynaria quercifolia, Polypodium Mayii, P. trioides and a fine specimen of Nephrolepis elegantissima. Messrs. MAY also showed, in another marquee, a miscellaneous group of flowering plants, including Verbenas, Heliotropes, Ixoras, Zonal Pelargoniums, a pink-flowered Abutilon, and many species and varieties of Polystichum and Scrolopendrium.

CALADIUMS.

Messrs. JOHN PEED & SON, West Norwood, London, S.E., exhibited a batch of Caladiums, not over large in size, but very brightly coloured. A fine plant of the variety John Peed having green leaves with reddish markings was a conspicuous object at the back. Other notable kinds were Sir Henry Irving (pale ground with red and green colouring), Oriflamme, Pallas, Alcibiades, Pantia Kalli, and Sir W. Broadbent.

Another handsome group of these plants was put up by Messrs. J. LAING & SONS, Forest Hill.

The arrangement adopted allowed each plant to be seen to advantage, Ferns being freely used between the specimens, with small Cocos Palms as foils. The front was pleasing, dwarf kinds such as Colonel John Hay, Argentea, and Prince of Wales being arranged in a setting of Asparagus, Betulionias, Saxifraga serotens, Nertea depressa, &c.

ROSES.

Messrs. W. PAUL & SON, Waltham Cross, Herts, made a fine effect with Roses at the entrance to the largest tent. The exhibit was of large dimensions, the blooms being all of first-class quality and representative of most of the best kinds in season. The surface of the group was pleasingly broken by a number of tall plants of pillar Roses, and nearer the front a number of epergnes were filled with handsome blooms of such kinds as Hugo Keller, William Allen Richardson, and Earl of Warwick.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, filled the corresponding end of the large tent with an equally beautiful exhibit of Roses as the last-mentioned. Roses of every description were to be found in this choice display, some being in baskets, others in epergnes and vases, whilst pot plants were disposed at points of vantage. Some of these pot plants were tall standards that overhung with a wealth of their pretty blossoms. We have no space to attempt a description of the many beautiful blooms staged, but we may mention as being especially fine, Celia, Hugh Dickson, Her Majesty, Queen Alexandra, Belle Siebrecht, and Hugo Keller.

Beautiful Roses in great variety were shown by Messrs. F. CANT & Co., Colchester. Along the front were exhibition boxes containing a wealth of varieties, each bloom being of exhibition quality, and at the back of these were vases, filled with garden varieties, and bunches of such beautiful varieties as White Maman Cochet, Countess of Gosford, Duchess of Portland, Dean Hole, Mrs. Ed. Maylew, Mildred Grant, Hugh Watson, and A. K. Williams.

Messrs. ALEX. DICKSON & SONS, Newtownards, Co. Down, showed an assortment of new Roses, the best of which were granted Awards of Merit. The following were also meritorious: Grace Molyneux, Eliz. Barnes, Harry Kirk, John Cuff, Florence Smith, and Mita Weddon.

Messrs. S. BIDE & SONS, Farnham, amongst a selection of Roses, had their new Queen of Spain variety in good form. Exhibits of Roses came also from the gardens of Col. W. HESSELTINE, Queen's Gate, S.W. (Mr. Butler).

HOBBIES, LTD., Dereham Nurseries, Norfolk, showed Roses, principally the popular pillar varieties such as Stella, Hiawatha, Minnehaha, and Lady Gay. These hung in festoons, and were trained over arches, whilst beneath were many choice blooms of T., H.T., and other large-flowering kinds. Some pillars crowned with Roses were entwined with *Vitis Henryana* and a pretty variegated Ivy.

Mr. CHAS. TURNER, Slough; Mr. GEO. MOUNT, Canterbury; Messrs. B. R. CANT & SONS, Colchester; Messrs. R. H. BATH, LTD., Wisbech; and Messrs. JARMAN & CO., Chard, all had excellent exhibits of Roses, and other exhibitors.

GLORINIANS AND BEGONIAS.

Messrs. JOHN PEED & SON, WEST NORWOOD, again contributed Glorinians in fine condition and in large numbers.

Messrs. THOMAS WARE, LTD., Feltham, made a splendid exhibit with tuberous-rooted Begonias, the display of double-flowered varieties being exceptionally fine. The Honourable Mrs. Maurice Glyn, Capt. Lafone, and Mrs. A. T. Brandt are all new varieties.

Messrs. J. LAING & SON, Forest Hill, showed tuberous-rooted Begonias, as a whole much behind the foregoing in every respect.

Mr. A. LL. GWILLIM was awarded a Silver Flora Medal for an extremely fine lot of tuberous-rooting Begonias.

Messrs. BLACKMORE & LANGDON, Twerton Hill, Bath, showed plants of tuberous-rooted Begonias, mostly of enormous sized blooms.

CARNATIONS.

A remarkably fine exhibit of Carnations was staged by Mr. A. F. DUTTON, Iver, Bucks, the blooms being of a high standard of quality. The group was very extensive, the blooms being staged in handsome glass vases, with trails of Smilax at their bases. There were most of the American or winter-flowering Carnations in this imposing group, and a fine selection of the winter type. A room was found for two banks of a new Ivy-leaved Pelargonium named Vincent Slade, the colour being rather brighter than the well-known Mme. Crousse variety.

Mr. W. H. PAGE, Tangle Nursery, Hampton, showed Carnations and Liliums, both of which flowers lend themselves to attractive arrangement, and which was fully taken advantage of by this exhibitor. Especially fine were large ferns filled with Carnations. Governor Rose-wood, Mrs. F. W. Lawson, and Enchantress, relieved with foliage of Pampas Grass.

Sir GEO. FAUDEL-PHILLIPS, Bart., Balls Park, Hertford (gr. Mr. F. Fitch), staged pot plants of Souvenir de la Malmaison and other Carnations. The specimens were very large; some were in 12-inch pots, and they were well furnished with choice blooms. A plant of the variety Churchwarden had upwards of 50 fine flowers.

Another handsome bank of Carnations was shown by Messrs. BELL & SHELDON, Guernsey, who showed Enchantress, Lady Bountiful, Mrs. Lawson, Harlowarden, Mrs. H. Burnett, The President, and other notable kinds in first-class style.

Mr. H. BURNETT, Iver, Bucks, had a charming display of Carnations in great assortment, arranged with artistic skill.

A group was staged by Sir DANIEL GOUGH, Hylands, Chelmsford. It was a finely interested display of small Palms and Ferns. At the back were large plants of Carnation Duchess of Westminster.

A small exhibit of Carnations was staged by JOHN KER, Esq., Loudwater, Rickmansworth (gr. Mr. Avery), and another batch of these flowers was shown by Messrs. JONES & SONS, Shrewsbury.

GREENHOUSE PLANTS.

Messrs. W. & J. BROWN, Peterborough, made a display with half-hardy flowering plants in great variety. That old garden plant *Trachelium cœruleum* was never seen in better flower; *Heliotrope Lord Roberts* was shown in beautiful bloom; several *Ageratum*s of the "nana" section were noted, also plants of *Verbena Miss Willmott*, capitally bloomed, as were small plants of *Hydrangea*. Roses were shown in good condition on boards and as large bouquets.

Messrs. W. CUTBUSH & SON, Highgate, showed Ivy-leaved Pelargonium James Atfield, a pink-flowered variety, very free to flower; the new *Colours Cordelia*, a quantity of *Verbenas*,

including Princess of Wales (deep blue), and The King (a bright crimson). A number of plants of *Erica Bothwelliana* (a rare variety nowadays in bloom); and *Begonia Phosphorescens*, a scarlet-flowered bedder, of dwarf habit, very bright in colour.

Messrs. T. ROCHFORD & SONS, LTD., Broxbourne, showed the new pink-flowered *Spiræas* Pinch Blossom and Queen Alexandra.

Messrs. RICHARD SMITH & CO., LTD., Worcester, showed a variety of greenhouse plants, and a number of large-flowered Clematis of the Jackman type. The flowering plants included Carnations, *Kalanchoe flamulata*, Liliums, Nymphæas and Nelines.

Zonal Pelargoniums in variety were shown by Mr. VINCENT SLADE, Staplegrave Nurseries, Taunton.

HARDY PLANTS.

Despite the fact that the displays of hardy plants at the Holland Park shows in previous years have reached a very high degree of excellence, never before have such imposing exhibits of these subjects been displayed. Very naturally, some few exhibits stand out more prominently than the rest, and in this sense the splendid exhibits from Mr. AMOS PERRY, Enfield, and Messrs. WALLACE & CO., Colchester, call for special praise. Indeed, it would be well-nigh impossible, in the limits of an exhibition such as this, to show anything finer, more naturally disposed, or covering so wide a field in hardy plant gardening as the magnificent groups arranged by Mr. AMOS PERRY in tent No. 3. Here were seen border subjects of most pleasing in season. Lilies in profusion, a delightful piece of rock-work, and a most pleasing, natural and picturesque water-garden. Extending the entire length of the tent and flanked at either extreme with bold groups of the choicest Larkspurs, the intervening space was occupied with plants of every description, from the more diminutive Alpines to the bolder Rushes and Sedges of the water-side and the giant Gunnera. The Water Lilies were a delightful feature, and played their part in a group that may be described as unique.

Somewhat to an extent, but admirably conceived and carried out, was the fine water garden and rockwork group arranged by Messrs. R. W. WALLACE & CO., Colchester. The group was arranged near to the entrance of the largest tent. By means of a stone path-way, in the midst of Japanese Irises, a water pool with stepping-stones led to a rock garden beyond, and from this point of view the effect was in every way excellent. Bold masses of *Spiræas*, *Aspidexes*, *Bullrushes*, *Burtonias*, *Eulalia*s, and other things adorned the margins of the water, and within the shelter of some of the settings some beautiful hardy Ferns were arranged. Apart from this portion of the exhibit, many choice Lilies, Early Gladioli, *Calochorti*, *Eremurus*, and other flowers in great variety were staged in capital form.

Another important and well-arranged group was that from Mr. M. PRICHARD, Christchurch, Hants. Here, too, were to be seen a great variety of subjects such as Lilies, *Iris Lavigata*, *Alstromerias*, *Eremurus*, *Bungei*, lovely masses of *Spiræa palmata* and *S. aruncus*, *Iris aurea*, *I. gigantea sulphurea*, a pale-coloured variety, and several good forms of the Day Lily, notably *Hemerocallis Baronii*, with long narrow petals of a pale primrose hue. The dark flower-buds, prior to expanding, render this a very distinct and attractive subject. Mr. PRICHARD also exhibited a very fine example of *Spigelia marilandica*.

Messrs. BARR & SONS, Covent Garden, had a capital display of hardy flowers, which included choice *Delphiniums*, *Iris Lavigata*, Water Lilies, English Irises, *I. aurea*, *I. Monnierii*, select species of Lilium, Cornflowers, &c. Messrs. BARR also showed a number of pigmy trees.

Messrs. PAUL & SONS, The Old Nurseries, Cheshunt, had many garden flowers, together with a superb and well-flowered batch of Lilium giganteum, whose long, drooping, trumpet-shaped white blossoms, stained internally with red, made a very striking display.

The Messrs. HOPKINS Sherrington, arranged a pretty rockwork exhibit planted judiciously with Alpine and allied things, the work being carried out in a very pleasing and artistic manner.

Mr. R. C. NOTCUTT, Woodbridge, had a capital group of hardy plants, amongst which Roses, flowering shrubs, and other subjects were interspersed freely.

Messrs. G. MALLETT & CO., Cheddar, also displayed a mixed group of hardy flowers, such things as Early Gladioli, Lilium auratum platyphyllum, and a capital lot of the Madonna Lily being noted.

Messrs. KELWAY & SON, Langport, had choice *Delphiniums* and *Gaillardias* both in great variety and staged as usual in a first-class manner.

Messrs. B. LADHAMS & CO., LTD., Shirley, Southampton, had an admirable group of hardy flowers, particularly fine being masses of perpetual flowering Pinks, the pure white *Campanula persicifolia alba coronata*, and a rich display of *Gaillardias*, the latter containing many good and distinct varieties.

Messrs. LILLEY & CO., Guernsey, staged early-flowering Gladioli, *Iris Lavigata*, and similar plants in abundance, together with a fine bank of *Alstromerias*.

Mr. A. J. UPTON, Hardy Plant Nurseries, Guildford, had many interesting things, such as *Sedum Middendorffianum*, *Lithospermum* in medium, with blue cylindrical-shaped flowers; *Adenophora liliiflora*, *Cistus algarvensis*, the petals being yellow with a dark base; *Campanula*, *Sempervivum* in variety, and *Pentstemon tubiflorus*, a white-flowered species, which is both graceful and free in its flowering.

The Misses KIPPING, Hutton, Essex, had a small though prettily-arranged group of Alpine and herbaceous plants.

Mr. H. C. PULHAM, Elsenham, Kent, arranged a rockwork exhibit and planted it with Alpines in diverse varieties. The same exhibit contributed a considerable variety of cut herbaceous flowers.

Mr. GEO. REUTHE, Keston, Kent, had an interesting variety of Alpines, rock-shrubs, and flowering herbaceous plants. Lilies, *Eremuri*, *Ixia*, *Calochorti*, a fine mass of *Morina longifolia*, some excellent examples of *Desfontainia spinosa*, together with *Sarracenia*s and other choice and good plants.

Messrs. WM. ARTINDALE & SON, Sheffield, had a mixed group of Alpine, herbaceous and flowering shrubs, also a fine collection of Pansees and Violas, the flowers remaining perfectly fresh and good throughout the show.

Messrs. GEO. JACKMAN & SONS, Woking, had many good hardy flowers in a nicely-arranged group. We noticed *Iris Lavigata* as grown in the open and in quite dry soil, *Scabiosa caucasica*, *Larkspurs* in variety, English and other Irises, and many other species.

A comprehensive group of cut garden flowers came from Messrs. GEO. BUNYARD & CO.'s nursery, Maidstone. The collection included Larkspurs in variety, *Alstromerias*, *Phloxes*, *Perennial Marigolds*, English Irises, also *I. aurea*, *I. Monnierii*, many fine *Campanulas* and a host of other good and seasonable subjects.

Messrs. GUNN & SONS, Olton, near Birmingham, had an admirable display of herbaceous *Phloxes*, of which *Etna*, *Aurora Borealis*, *Coquelicot*, and *Tapis Blanc* were notable examples.

Messrs. G. & A. CLARK, LTD., Dover, contributed a fine group embracing Alpines, Sweet Peas, herbaceous plants, rock-flowering shrubs, aquatic and allied things. A group of *Gilla coronopifolia* and a fine spike of the Lizard Orchis, *O. hircina*, collected near Dover attracted much attention.

Mr. HOWARD H. CRANE, Woodview Terrace, Highgate, London, N., had a very pretty display of Violas arranged in shallow pans. Several dozen of these pans, each containing a distinct variety, were staged, and there was also a delightful gathering of the more miniature *Violettas*, both as cut flowers and as growing plants in pans to demonstrate their dwarfness and freedom of flowering.

Messrs. T. S. WARE, LTD., Feltham, had a large and varied exhibit of seasonable hardy herbaceous and other flowers.

SWEET PEAS.

Rarely have Sweet Peas been exhibited in greater numbers than on this occasion, the quality of the exhibits being very fine. At the entrance to tent No. 4 Messrs. JAMES CARTER & CO., High Holborn, staged a large number of varieties in vases and suspended from arches, the exhibit being a most effective one. *Gloxinias* were arranged in the centre of this pretty display.

Mr. C. W. BREADMORE, Winchester, had an admirable display of Sweet Peas skillfully

arranged with their own foliage. Notable varieties were *M. George*, Queen of Spain, Henry Eckford, King Edward VII., and The King.

Messrs. G. STARRK & SON, Great Ryburgh, Suffolk, in a very comprehensive group, displayed many excellent varieties, noteworthy sorts being *Sir George*, *George Starrk*, a new variety with flowers of a reddish-scarlet hue; *Oliver Kussell*, a very delightful shade of pink; and *Helen Pierce*, blue.

Mr. W. K. CHAPLIN, Joyvings Nurseries, Waltham Cross, also exhibited these flowers freely and in many choice varieties.

Messrs. E. W. KING & CO., Coggeshall, Essex, had a delightful stand of Sweet Peas, including some of the newer and more distinct sorts, such as *Mrs. Wm. King* (rosy carmine), *Anglian Blue*, *White Spencer*, *Evelyn Hemus*, and *Blush Seeding*.

Messrs. JONES & SONS, Shrewsbury, also displayed these flowers in large numbers and in variety, the collection including the leading novelties as well as the best of the older kinds.

Messrs. SUTTON & SONS, Reading, staged a very complete collection in excellent condition. There were probably not fewer than 200 varieties, the centre being occupied with a bold arrangement of Sutton's Queen, a lovely variety of pink and cream colours.

Other exhibitors of Sweet Peas included Messrs. S. BIDE & SONS, Farnham; Mr. H. HEMUS, Upton-on-Severn; Messrs. J. KING & SONS, Coggeshall, Essex; and FRANCIS WELLESLEY, Esq., J.P., Woking.

GROUPS OF PLANTS EXHIBITED OUT-OF-DOORS.

Mr. JOHN FORBES, Hawick, N.B., made a large display with *Phlox* *decussata* in considerable variety, *Violas*, *Pansies*, *Delphiniums*, &c. Of the first-named plants, the varieties *Esperance* (of a lilac colour, having a white star in the middle), *Croisade* (pale blue and white), *Joseph Chamberlain* (mauve purple), *Josephine Gerbaut* (white, with a pink eye), *John Lambert* (reddish lilac), and *W. P. Wright* (bright purple) are choice garden kinds. *Delphiniums* with long spikes, densely clothed with blooms, the colours being especially pleasing in the varieties *Bertram*, *Albert Edward*, *Life Guardsman*, and *Norah Green*. *Violas* and *Pansies* were extensively shown. Among the latter several remarkable or bold markings were noted.

Messrs. JAMES VEITCH & SONS, LTD., Royal Exotic Nursery, Chelsea, exhibited a group of small plants of hardy *Fuchsias*, consisting of species and hybrids, viz., *triphylia*, *Thomsonii*, *myrtilifolia*, *gracilis*, *variegata*, *coccinea*, *Floriana*, *Riccartonii*, *Drama*, &c.

Messrs. THOS. CRIPPS & SON, LTD., Nurserymen, Tunbridge Wells, showed hardy trees, many of them Japanese *Acers* in variety, grown as standards so as to show nice effects; new Chinese *Vitis* of species, *Thujas*, *Clematis*, *Retinospora obtusa* (Crippis), a pretty golden yellow variety, and other variegated plants in considerable numbers, and all of them hardy in this country.

Mr. L. R. RUSSELL, The Richmond Nurseries, Richmond, exhibited tree *Ivies* of a golden-leaved variety as standards and bushes. The taller plants were wonderfully effective. This exhibitor had likewise a large group of silver and gold variegated trees and shrubs, and capital specimens of *Aralia*, *Mandshurica* argenteo-variegata, *Hydrangea Hortensia*, *Aucuba Acer*, *Vitis*, &c. The arrangements of this group and that of the others were more lightsome and diversified than we have observed in former years.

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, constructed a pergola with Larch poles, clothing the supports with *Clematis* and *Rambler* *Roses*; whilst at the back and ends plants in pots were employed to enclose the whole. We noticed well-bloomed plants of *Philadelphus latifolius*, a neat specimen of *Abies pincens glauca*, a pretty group of pot plants of *Rose Mme. Levasseur* in full bloom, *Lilium auratum*, &c.

Messrs. M. FROWSON & SONS, Sutton Court Nursery, Chiswick, set up a large group consisting of such hardy subjects as Japanese *Acers*, variegated *Ivies* and *Bamboos* ranging from 10 feet to 2 feet in height.

Messrs. H. LANE & SON, The Nurseries, Great Berkhampstead, showed *Buxus japonica* *aurea*, *Taxus elegantissima*, golden tinted in the new growth; *Retinospora pisifera aurea*, *Cypres-*

sus Lawsiana, *C. Lambertiana lutea*, and other variegated *Cypresses*.

Messrs. GUNN & SONS, Olton, Warwickshire, showed their new *Phlox* "*Lapis blanc*," the plants being about 2 feet in height, robust, with big flower-heads, of smooth-edged, circular blooms 1½ inch in diameter.

Mr. W. PINGO HORTON, of the Stafford Road and Sunnyside Market Nursery Co., Cravenhurst, Seaford, Sussex, showed a novel arrangement in a sloping frame fitted with wooden stages having a front of virgin cork, filled with a number of rare and choice plants. We noted a new seedling, *Gerbera Jamesoni*, of a rich scarlet colour, one of many that he has raised; a cross between a Sweet William and *Carnation* *Uriah Pipe*, a sky-blue *Nemisia* looking like a blue *Lobelia*, a double-flowered *Monophasis cambrica*, *Pentstemon coruleus*, *Osmunda palustris*, &c.

Mr. G. KEITHE, The Fox Hills Nursery, Keston, showed a small group of plants consisting of *Irises*, *Campanulas*, *Saxifragas*, *Water Lilies*, &c.

AWARDS.

AWARDS OF MERIT.

Begonia Duchess of Cornwall.—This variety has fine, double flowers of rich crimson, the form being similar to a well-developed *Camellia*. Shown by Messrs. BLACKMORE & LANGDON.

Begonia Frilled Queen.—Of the many frilled *Begonias* exhibited in recent years, this one may be described as the most remarkable. The flowers are single, and the frill is developed in an unusual degree. The rich shade of pink is pleasing. Shown by Messrs. BLACKMORE & LANGDON.

Delphinium "Progression".—This is a white variety, except for a very little yellow in the centre. It is distinct from any we have observed. Shown by Messrs. WALLACE & CO.

Delphinium "Statuaria Rude".—This is a magnificent variety, with very large, semi-double flowers of a pale mauve colour. The inflorescence is long and bold, and the novelty may be recommended as distinct and of great merit, however much one may be disposed to question the appropriateness of the appellation. Shown by Messrs. BLACKMORE & LANGDON.

Rose George C. Waud.—This Hybrid Tea variety is remarkable for its brilliant colour, being a shade of cerise red as it appeared to us, but it has been described by the raisers as orange-velvet. The flowers are large, of excellent form, and the petals wide and good. This variety should prove an excellent one for market supply, and we are glad to note that it possesses perfume. It has been shown previously under the name *Sir Henry Irving*, but this has been altered because a *Rose* has already been distributed in America under the name of *Henry Irving*. Shown by the raisers, Messrs. ALEX. DICKSON & SONS.

Rose Mrs. David Jardine.—Of the four varieties which obtained Awards on Tuesday last, this one commended itself most to us. It is a Hybrid Tea, and the flowers are of the very best form, having high, well-developed centres. In colour it is a most pleasing shade of shell-pink. The habit of the plant appears to be erect and vigorous, and the variety is said to have proved first-rate for forcing. We have no hesitation in commending this novelty as being one of the prettiest and most desirable of its type, which is that of the *Catherine Mermet* section. Shown by the raisers, Messrs. ALEX. DICKSON & SONS.

Rose Molly Sharmar Crawford.—This is a pure Tea variety, with large, well-formed flowers possessing good centres. The petals are very fine, and reflex prettily from the centre of the flower, which is white or very pale lemon. Shown by the raisers, Messrs. ALEX. DICKSON & SONS.

Rose Florence Edith Coulthwaite.—A Hybrid Tea variety of a salmon pink shade, varying considerably in the different flowers. As shown, the blooms were scarcely so attractive as the varieties already mentioned, but it is described by the raisers as one of their best novelties. Shown by Messrs. ALEX. DICKSON & SONS, who are also the raisers.

Viola Ernest Needham.—A very large, slightly-retired *Viola* of perfectly circular form. The colour is purple on the margins, and the rest

white, except for a little yellow in the centre. Shown by Messrs. WM. ARTHURDALE & SON, Sheffield.

Tunica Saxifraga fl. pl..—A pretty, double-flowered form of this *Caryophylloaceous* plant. The blossoms measure nearly half an inch in width, are semi-double, and of a pink shade, deeper than in the type. In other respects it is identical with the older form, and will be found of use for planting in trailing over rocks or boulders, or for serving in old walls and ruins. Shown by Mr. G. KEITHE.

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the Chair), and Messrs. Jas. O'Brien (hon. sec.), H. Little, H. J. Chapman, H. A. Tracy, H. G. Alexander, F. Sander, J. Charlesworth, W. Boxall, F. M. Ogilvie, G. F. Moore, de B. Crawshaw, Gurney Wilson, Walter Cobb, Sir Jeremiah Colman, W. Bolton, J. Forster Alcock, A. Dye, R. G. Thwaites, W. H. White, F. J. Hanbury, Stuart Low, and C. H. Curtis.

In the large tent, the central staging in which was devoted to Orchids, Messrs. CHARLESWORTH & CO., Heaton, Bradford, staged a magnificent group, equal in quality and in good arrangement to any which has yet been staged at Holland House. With a background of graceful Palms, the salient feature throughout was made by the many splendid forms of *Laelio-Cattleya* *Fascinator*, *L.C. Aphrodite*, *L.C. Canhamiana*, *L.C. callistoglossa*, &c., raised at Heaton. Very remarkable among these were two fine specimens of the deep-coloured *L.C. Canhamiana* *Fire King* and several *L.C. C. albata* the rich orange-crimson *L.C. Golden Oriole*, and a very dark-coloured *L.C. Berthe Fournier*. Among the *Cattleyas* were a fine set of white forms, a grand specimen of *C. Mossie Wageneri*, having a dozen pure-white blooms; two plants of the rare snow-white *C. Warneri* *alba*; *C. Mendelii* *Queen of Spain*, with many white flowers, having an orange disc with light rose marking in front; and various other pretty forms. *Odontoglossums* were also finely shown, and in these the Heaton-raised forms were conspicuous, varieties of *O. ardentissimum* including both the deep purple-spotted and the clear-white variety *xanthotes*. *O. Othello*, *O. Rolfeae*, and *O. crispum* were also good, the heavily-blotched *O. crispum* *The Khevide* being of great beauty. Of specially rare and good things noted were *Odontodia Charlesworthii*, with fine red flowers; *O. Lutetia* (*C. Noelliana* × *O. luteo-purpureum*), marked with a peculiar yellowish-red colour; *Odontoglossum hibernicum*, and other new hybrids. Of interesting species there were a good display.

Messrs. SANDER & SONS, St. Albans and Bruges, staged a very fine group, or series of groups combined, the two end sections being composed of their new foliage plants, many of which were recently illustrated in the *Gardener's Chronicle*. The central and taller portion of the main groups of Orchids had tall, graceful Palms at the back, from which arched forward the fine white sprays of *Phalaenopsis amabilis* *Rime-stadiana*, in front of which was a very handsome selection of varieties of *Laelio-Cattleya* *Martinetii*, the rich, Indian-red petalled varieties, with deep reddish-purple labellums, predominating, and the best of these were named *Princess Rex*, and *Vulcan*. The taller curves had for a background the feather-foliated *Polypodum Knightii*, the side groups having elegant Palms at the back. Very fine in the body of the group were the varieties of *Odontoglossum* *Harryano-crispum* *Brugense*, raised at Bruges; the varied and beautiful forms of *O. ardentissimum*, including the beautiful varieties *Rosy Moon*, *Kalisto*, and others. Among the forms of *O. crispum* were several very fine blotched varieties. The *Cattleyas* were represented by the very fine set of *C. Warscewiczii* *Sanderiana*, good *C. Mossie*, including the pure white *C. M. Wageneri*, *C. M. Reineckiana*, and several other white forms. Three specimens of *Odontodia Lairessee* bore fine branched sprays of their white and rose-coloured flowers, and other good hybrids were included. In one pretty group were a fine set of *Cypripedium bellatulum*, beside them being the still larger and more beautiful *C. Godfreyae* *leucocolum* "The President," a noble and richly-marked flower, the finest *Cypripedium* in the show; and behind them the handsome *Cypripedium* *Orion* (*Selligerum majus* × *Rothscheldianum*), its large

ivory-white, purple-striped dorsal sepal being broader than long. Species of Orchids were many and various.

Messrs. MOORE, LTD., Rawdon, Leeds, had a very interesting and tastefully-arranged group, the backing of which was of plumose Cocos Palms. Three stands with virgin-cork pockets, in which to arrange the plants, were carried up, the central one having five varieties of Cattleyas, some of the *C. Warszewiczii* being very beautiful. In front was the elegant plant of *Oncidium conigrum*, with its gold and brown flowers gracefully drooping, beside it being the pretty *Epidendrum nemorale*, the pure white *Cattleya Gaskelliana* alba, *Brassia verrucosa*, the finely-blotched *Odontoglossum eximium*, *O. amabile*, and other *Odontoglossums*. Two well-flowered plants of the large rose-purple *Disa Luna* were very effective; the rare *Cirrhopetalum biflorum*, with five spikes each of two pretty rose-coloured flowers, the feather-lipped *B. barbigatum* were interesting objects, and among others noted were the carmine-crimson *Broughtonia sanguinea*, the rare *Vanda Bensonii* an-

Claptonense, and the elegant rose-purple *Cirrhopetalum Cumigii* were noted, and in another arrangement several *Sophranochilus*, *Physosiphon Loddigesii*, *Epidendrum pentoties*, *Oncidium ranitrum*, and other species.

Messrs. STANLEY & CO., Southgate, staged a group in which *Cattleya Warneri* was well represented, the variety *magnifica* being very fine. Among the forms of *Cattleya Mossiae*, the variety *Silver Queen* was a good white, and the forms of *C. Mendelii*, *Oncidium sarcodes*, *O. macranthum*, &c., were well displayed.

Mons. FLORENT CLAES, Etterbeek, Brussels, showed several very fine forms of *Cattleya Mendelii* and *C. Mossiae*, the best of which was *C. Mendelii*, Claes' variety, a model white flower, with carmine crimson front to the lip.

Mons. A. A. PETERS, Brussels, showed *Cattleya Bowringiana-Schubertiana*, with deep purplish-claret flowers; *C. Du Prezana* (Warneri × *Warszewiczii*), larger than *C. Warszewiczii* and similarly coloured; and *C. Carducea* (Schofieldiana × *Gaskelliana*).

ing deep rose lines on the lip; and the large white *M.V. Queen Alexandra*.

W. THOMPSON, Esq., Walton Grange, Stone (gr. Mr. Stevens), sent *Odontodia Charlesworthii*, with deep red flowers with yellow crest.

AWARDS.

FIRST-CLASS CERTIFICATE.

Laelio-Cattleya Clite magnifica (L. præstans × L.-C. Downiana aurea), from Lt.-Col. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander). A superb dwarf *Laelio-Cattleya*, with large flowers, having the sepals and petals deep rose colour, the lip purplish-claret, with gold-coloured lines from the base.

Odontoglossum illustre "King of England," from H. S. GOOSION, Esq., West Hill, Putney (gr. Mr. G. E. Day). One of the most beautiful hybrid *Odontoglossums*. Flowers large, all the segments broad, the sepals and petals heavily blotched with bright violet, the lip chocolate-purple, with white margin, and strongly indicating *O. Vuytstekei* as one of the parents.

AWARD OF MERIT.

Odontoglossum Eleanor, *Westonbirt variety* (*cirrhosum* × *Uro-Skinneri*), from Lt.-Col. G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. Alexander). A charming hybrid, with sage-green sepals and petals spotted with chocolate colour and broadly ovate-acuminate white lip marked with violet-purple.

CULTURAL COMMENTATION.

To Mr. H. G. Alexander, Orchid grower to Lt.-Col. G. L. HOLFORD, for a magnificent plant of *Odontoglossum Othello*, *Westonbirt variety*, with two very stout spikes of large and handsome flowers.

To Mons. CHAS. VUYSTEFKE, Loochristi, Ghent, for the original plant of *Odontodia Vuytstekei*, very finely flowered, with a large branched spike of white and reddish-rose flowers, in which cultivation has developed more of the fine size and white ground colour than in the specimen when originally exhibited.

Fruit and Vegetable Committee.

Present: G. BUNYARD, Esq. (Chairman), and Messrs. W. Bates, W. Poupard, H. Parr, W. H. Divers, G. Woodward, J. Davis, Thos. Coomber, E. Beckett, J. Willard, W. Fyfe, G. Kelf, C. Walter, J. Cheal, P. C. M. Veitch, A. R. Allan, W. Pope, R. Lye, G. Wythes, C. Foster, J. Bashaui, and A. Dean.

Although a meeting of this Committee was held, very few subjects were presented for adjudication.

W. H. P. STUGIS, Esq., Givons Grove, Leatherhead (gr. Mr. Peters), sent several seedling Strawberries in dishes, also plants in fruit of the varieties William Peters and Marmaduke. All the varieties were tasted, but none met with the approval of the Committee.

Messrs. HUGH LOW & CO., sent a hybrid Blackberry, the product of crossing the Loganberry with a British Blackberry. (See figs. 12 and 13.)

Although the customary fine collection of pot fruit trees from Sawbridgeworth was lacking, there was much of interest in the fruit exhibits. Notably fine was a collection of some 80 representative fruit trees staged by Messrs. JAS. VEITCH & SONS, King's Road, Chelsea, prominent amongst which were Standard trees of Red Currants in good fruit on 6-foot stems; also some tall Gooseberries. Figs were in good form, such varieties as Black Ischia, Negro Largo, Early Victor, Bourjassotte Grise, Violette de Bordeaux and Early Violette being well fruited. At the back of the collection on either side were Madresfield Court and Black Hamburgh Grapes, and on the other side Royal Muscadine and Foster's Seedling. These were flat-trained and heavily fruited. Apple Coronation was in good fruit, as also were Peaches Dymond, Stirling Castle, Peregrine, and Duchess of Cornwall, and Nectarines Pine Apple, Humboldt, Cardinal, and Dryden.

Messrs. G. BUNYARD & CO., LTD., Maidstone, had a collection of some 30 pot trees, including Peaches Duchess of Cornwall and Duke of

FIG. 12.—THE NEW HYBRID BERRY SHOWN BY MESSRS. HUGH LOW AND CO., AT THE HOLLAND PARK SHOW. (See p. 37.)

chorifera, *Zygopetalum rostratum*, *Bulbophyllum Godsefianum*, some specially good *Milnionia vexillaria*, and a singular variegated form of the yellow *Lycastris macrobulbon*. *Odontoglossum Rolfeae magnificum* was a grand form, large in size and equally broad in all its parts; white, prettily marked with purple, and one of the most perfectly formed of hybrid *Odontoglossums*.

Messrs. HUGH LOW & CO., Enfield, had a fine group of *Cattleya Mendelii* and *C. Mossiae* of their well-known excellent type. One specimen of *C. Mendelii* bore about 30 flowers, and all were exceptionally well bloomed. Among the white varieties of *Cattleya Mossiae*, specially interesting was the large and beautiful *C. Mossiae Arnoldiana Smees* variety, which the firm originally sold to the late Dr. Smees nearly 25 years ago, and which is still one of the best. A batch of the white *Cyrtopetalum niveum*, a pretty selection made up of varieties of *Bulbophyllum Lobbiani*, *B. Siannense*, the beautiful *B.*

H. S. GOOSION, Esq., Putney (gr. Mr. G. E. Day), showed *Odontoglossum Pescatorei* *Sidneyanum*, a very large white flower, with the lip hands mely marked with violet; a good *Cattleya F. W. Wigan*; and *Odontoglossum illustre* "King of England" (See Awards.)

Lt.-Col. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), sent *Sophranochilus-Cattleya Danae* (S.-L. *laeta* *Orpetiana* × *C. Harrisoniae*), a very pretty hybrid, with purplish-rose sepals and petals, and lip formed like *C. Harrisoniae*, yellowish, with rose tip; and three others. (See Awards.)

WALTER COBB, Esq., Rusper (gr. Mr. C. J. Salter), showed *Odontoglossum formosum*, Cobb's variety, white, heavily blotched with violet, and formed like *O. Pescatorei*.

F. M. OGILVIE, Esq., The Shrubbery, Oxford, showed *Milnionia vexillaria*, The Shrubbery variety, a large rose-pink variety, with radiat-

York; Plums heavily fruited; Apples Hit him Pippin and Peasgood's Nonsuch; Cherries Monstreuse de Mezel, Kent Bigarreau, Comiti de Heffelungen, and others. The firm also exhibited in plates various well-kept Apples, including Tibbett's Pearmain, Smart's Prince Albert, and Calville des Femmes, and in small boxes a collection of Strawberries showing excellent fruits of The Bedford, Progress, British Queen, Eleanor, Laxton's Latest, Waterloo, Louis Gauthier, and others.

From S. HEILBUT, Esq., Maidenhead (gr. Mr. J. Camp), came a dozen fine trees, chief amongst which were some superbly-fruited Cherries. Specially heavily fruited were trees of the varieties Bigarreau Napoleon, Empereur Francis, and Bohemian Black; several Peaches and Nectarines, the names of which were not visible; and Brown Turkey and Black Naples Figs were also shown by Mr. HEILBUT.

Gathered fruit was represented by a collection of 19 fine Queen Pineapples from Lord LLANGATTOCK'S garden, The Hendre, Monmouth (gr. Mr. Coomber). The fruits were presented in the best condition, for which Mr.

Mr. S. MORTIMER, Rowledge, Farnham, had a collection of superb Melons, 60 fruits in all, those of Hero of Lockinge being exceptionally fine. Other varieties were Sutton's Royal Favourite, Windsor Castle, and Bleinheim Orange. There were very handsome samples of Cucumbers Evergreen and Faultless; also boxes of Up-to-Date, Sunrise, and Hanwell Victory Tomatoes.

Messrs. ADAM PARKER & Co., Waltham Cross, had two baskets and three dishes of unnamed Tomatoes.

VEGETABLES.

Practically the only collection—and that a remarkably fine one—came from Aldenham House Gardens, Mr. E. Beckett (gr. to VICARY GIBBS, Esq.) being the exhibitor. It comprised 102 separate dishes, and was probably one of the finest displays ever shown by Mr. Beckett at this season of the year. There were some 50 very perfect heads of Cauliflower, including Purity, Magnum Bonum, White Queen, and Early Giant. Intermingled with these were Allan's Early, Little Gem, and Tender and True

length, deep black in colour, and pleasing to the palate. Shown by Messrs. HUGH LOW & Co.

Awards made by the Council.

GOLD MEDALS.

The Rt. Hon. Lord Llangatock, The Hendre, Monmouth; The Hon. Vicary Gibbs, Aldenham House, Epsom; Frank Cant & Co., Colchester; Charlesworth & Co., Heaton, Bradford; A. F. Dutton, Iver, Bucks; H. Gibbs, Ltd., Dereham; H. E. May & Sons, Exeter; Paul & Son, Cheshunt; William Faul & Son, Waltham Cross; Amos Perry, Enfield; J. Vetch & Sons, Ltd., Chelsea; and R. Wallace & Co., Colchester.

SILVER PAGES.

C. W. Broadbent, Winchester; James Carter & Co., High Hill; W. W. Burch & Son, Highgate; R. & G. Cutbber, Southgate; L. R. Russell, Richmond; G. Bonyard & Co., Maidstone; G. A. A. Clark, Dover; Sander & Sons, St. Albans; Hugh Low & Co., Bush Hill Park, Enfield; M. Pritchard, Christchurch, Hants; H. Campbell & Sons, Swanley; T. Cripps & Sons, Tunbridge Wells; Blackmore & Langdon, Twerton, Wilts; Nursery, Bath; W. Arndale & Son, Nether Green Nurseries, Sheffield; W. H. Page, Hampton, Middlesex; S. Heilbut, Esq., Holsport, Maidenhead; A. Dickson & Sons, New Barnard; B. R. Cant & Sons, The Rose Gardens, Colchester; Bell & Sheldon, Castel Nursery, Guernsey; J. W. Moore, Ltd., Rawdon, Leeds; T. Green & Son, Ltd., New Surrey Works, Southwark Street, S.E.; and W. Bull & Sons, Chelsea.

SILVER-GILT FLOWER MEDALS.

T. S. Ware, Feltham; Barr & Sons, Covent Garden; Jackson & Son, Woking; Feed & Son, West Norwood; W. R. Chaplin, Waltham Cross; W. Bull & Sons, Chelsea; G. Mount, Canterbury; Cheal & Son, Crawley; and Wood & Son, Wood Green.

SILVER-GILT KNIGHTIAN MEDAL.

Laxton Bros., Bedford.

SILVER-GILT BANKSIAN MEDALS.

Misses Hopkins, Shepperton; G. Reuther, Keston; R. H. Bath, Lill, Wisbech; C. C. Turner, Slough; E. W. King & Co., Coggeshall; and H. Burnett, Grimsby.

SILVER FLOWER MEDALS.

Sir G. Faudel-Phillips, Hertford; R. C. Notcutt, Woodbridge; Lang & Sons, Forest Hill; F. Lilley, Guernsey; Gunn & Sons, Olton; A. L. Gwillim, New Eltham; Bide & Sons, Farnham; Stark & Sons, Great Ryburgh; H. C. Fulham, Epsenham; Jones & Son, Shrewsbury; John Forbes, Hawick; Lane & Son, Berkhamstead; Meryweather & Son, Southwell; E. Laddington, Ltd., Southampton; King's Acre Nurseries, Hereford; W. Frowan & Sons, Chiswick; Sutton & Sons, Reading; Stanley & Co., Southgate; G. W. Riley, Herne Hill; Scott & Sons, South Norwood; Inmans & Co., Stretford; Potter's Art Guild, Compton; and Fulham & Son, Newman Street, W.

SILVER KNIGHTIAN MEDALS.

S. Mortimer, Farnham, Surrey; Swanley Horticultural College (gr. Mr. Lawson); R. Jackson & Co., Piccadilly; and Miss C. E. Martin, New York, U.S.A.

SILVER BANKSIAN MEDALS.

R. Smith & Co., Worcester; G. Mallett & Co., Cheddar; Kelway & Son, Langport; H. P. Burrell, Esq., Horton; Dr. Freeland; E. E. Gimson, Esq., Sutton, Surrey; Col. Heselbine, 106, Queen's Gate; J. R. King, Sons, Coggeshall; E. N. M. Kipping, Hutton, Essex; V. Slade, Tanton; A. R. Upton, Guildford; F. Wellesley, Esq., Woking; W. J. Brown, Stamford; Patent Ladder Co., Peterborough; Castle Shipbreaking Co., Millbank; de Lucy Frees, Canberwell; A. Hamilton, 11, Conduit Street, W.; Liberty & Co., Warwick Street; Ransomes, Sims & Jefferies, Ipswich; E. Vesmaacotti, Leadenhall Street; and Lloyd, Lawrence & Co., Worship Street.

BRONZE BANKSIAN MEDALS.

Headley & Edwards, Cambridge; James George, Putney; Dowell & Son, Hammersmith; Feilon & Son, Tudor Street, E.C.4.; W. Herbert & Co., Hop Exchange, E.C.3.; Syrt & Co., Wilson Street, Fishbury; and A. Shanks & Son, Bush Lane House, E.C.

TRIAL OF EDIBLE PEAS.

A deputation from the Fruit and Vegetable Committee, with Mr. J. Cheal as chairman, inspected early Peas in the Society's gardens, Wisley, on June 24. Some 47 stocks, previously awarded to Quite Content, Duke of Albany, and Stratagem, from Messrs. Jas. Carter & Co. were confirmed. It was resolved to recommend for Awards of Merit at the meeting of the Committee on July 21 several seedlings if then duly named, also the dwarf varieties Delicatessen and Daffodil, all being fine croppers. A few Long Pod Beans were seen, the best stocked being White Leviathan, which seemed to be identical with Seedling Long Pod.

BATTERSEA AND WANDSWORTH CHRYSANTHEMUM.

JULY 4.—Through the kindness of Sir Jeremiah Colman, a party of members and friends, numbering 70, paid a visit to Gatton Park, Reigate, on the above date. The head gardener, Mr. W. P. Pound, conducted the party through the glass-houses and grounds, pointing out everything of interest. The famous "Marble Hall" was much admired; other interesting features were the quaint old Lion Hall, surrounded by trees, and the old church.

FIG. 13.—HYBRID BERRY "LOW JUNIOR" (BLACKBERRY X LOGANBERRY).
(See Awards at Holland House show.)

Coomber is noted. He had also a collection of 16 varieties of Strawberries set up in shallow boxes. These included of scarlet hue, Trafalgar, Royal Sovereign, Fillbasket, and The Bedford; white, Louis Gauthier; and of deeper colours, Sir Joseph Paxton, Givon's Late Prolific, Bedford Champion, Leader, Reward, Sir C. Napier, President Lubet, Laxton's Latest, Gunton Park, and Waterloo.

From the HORTICULTURAL COLLEGE, Swanley, Kent, was sent a collection of Melons and other fruits. There were 15 Melons, all fine clean fruits, and apparently of the variety Miss Wilkinson, so named after the Lady Principal. There were also bunches of Black Hamburgh Grapes, Diamond Peaches, Superlative Raspberries, Beauty of Bath Apples (very fine), Red Currants, and several dishes of good red and yellow Tomatoes.

Messrs. LAXTON BROS., Bedford, put up a collection of 40 baskets of Strawberries, the fruits generally being exceptionally fine. Specially noticeable were Laxton's Latest (fruits large and dark in colour), Reliance, Waterloo, Progress, The Bedford, and Givon's Late Prolific. The varieties were generally late ripeners. Some good fruits of Peaches Duke of York and Alexander, and Nectarine Lord Napier, were also shown well by this firm.

Cabbages, various Cabbage Lettuces, white Seakale, Beet, Marrows, Carrots, Rhubarb, and other culinary products. Fronting these were Peerless, Matchless, and Delvacy Cucumbers; Perfection, Eclipse, Sunbeam, and Golden Perfection Tomatoes; Ringleader, Duke of York, Windsor Castle, and other Potatos; Mammoth Long Pod Beans; Early Giant, Duke of Albany, and Centenary Peas; various short Carrots; wax-podded and green Dwarf Beans; Mustard and Cress, and many other vegetables.

Messrs. JAS. CARTER & Co., Holborn, surrounded their pretty exhibit of flowers with some 60 dishes of edible Peas, including many evidently fine samples from crosses of well-known varieties, but the seedlings were shown under numbers. Of named varieties, capital samples were staged of Quite Content, Telephone, Gladstone, Early Morn, Alderman, Edwin Beckett, Stratagem, Standard, and others.

AWARD OF MERIT.

Low Junior Blackberry x Loganberry (see figs. 12 and 13).—This fruit was obtained by crossing the native Blackberry with the Loganberry. The fruits, which had been ripened under glass, were about 1 or 1½ inches in

NATIONAL ROSE.

JULY 3.—Everything tended to ensure success for the Metropolitan exhibition of the National Rose Society, which was held on the foregoing date in the Royal Botanic Society's Gardens, Regent's Park. The weather was glorious, the arrangements were perfect, and the season has on the whole proved a good one for the flowers. The attendance of the public was probably a record for these shows. The patrons of the Society are increasing in number, and the membership is now second only to that of the Royal Horticultural Society. Amongst the visitors were Her Majesty the Queen and Princess Victoria, and they were conducted through the tents by Miss Willmott, the hon. secretary (Mr. Ed. Mawley), and other officials.

The general quality of the flowers was good but not exceptional, and it was noticeable that some of the older favourites, such as Ulrich Brunner, Mrs. John Laing, and Maman Cochet, were exceptionally fine this season, but the beautiful Frau Karl Druschki was not equal to the blooms of previous years. Two new varieties received Gold Medals, but neither appeared to be up to the highest standard, and we doubt if they will rank amongst the best varieties in the future.

As the day wore on the blooms lost much of their beauty, for the intense heat caused them to droop and to lose their colour. A thermometer in the open registered 112° at 1.30 p.m., and we were informed that inside the tents the thermometer rose to 75°. In order to make the tents more comfortable, a stream of cold water was directed on to the canvas outside and the sides were opened to permit of ventilation. The number of entries eclipsed all records and necessitated an extra tent, which was used exclusively to accommodate the decorated tables and other devices of the florists' art. The thanks of all are due to the hon. secretary (Mr. Ed. Mawley) and his assistants; also Mr. Jones and others of the staff of the Botanic Society for the admirable arrangements. The catering in the refreshment department was inadequate and caused considerable dissatisfaction.

NURSERYMEN'S CLASSES.

CUT BLOOMS.

The first class in the schedule is also the first in importance, and the one that causes the greatest amount of interest. No fewer than 72 blooms of distinct varieties are required in the Nurserymen's Champion class, and it attracted five of the premier Rose firms. The winners of the 1st prize were Messrs. D. PRIOR & SON, Myland Nursery, Colchester, with generally a very creditable lot of blooms. *Back Row*: Oberhoigartner Tercks, a magnificent bloom; Ulrich Brunner, Mildred Grant (both these varieties were universally good throughout the show); Suzanne Marie Rodocanachi, Papa Lambert, Horace Vernet, Frau Karl Druschki, Duke of Edinburgh, Lohengrin, A. K. Williams, Alice Lindsell, François Michelon (silvery-rose), Hugh Watson (the petals are rose with a peculiar orange shade, a pleasing tint), Helen Keller, Mrs. Sherman Crawford, Etienne Levet, Marchioness of Dufferin, Marchioness of Londonderry, Dupuy Jamin (carmine), Alice Cochet, Florence Pemberton, and William Shean. *Middle Row*: Liberty, Mrs. Marie Correll, Maman Cochet, John Stuart Mill, White Maman Cochet (a choice flower), Marie Baumann, Robert Scott, Duke of Teck, Mrs. John Laing, Duke of Connaught, Marchal Niel, M. L. Poivet, Bessie Brown, Chas. J. Grahame, Dean Hole (a fine representative of this beautiful variety), Muriel Grahame, Gladys Harkness, Mme. Delville, Mme. Jules Graveraux, David Hatum, Mrs. Theodore Roosevelt, J. B. Clark (a well-formed bloom, richly coloured), Caroline Testout, and Killarney. *Front Row*: Duchesse de Normy, Oscar Cordel, Countess of Caledon, Bob Davison, Mrs. David M. Kee, Doctor Sewell, Princess Marie Merckertsky, Ben Cant, Marchioness of Devonshire, Victor Hugo, Mrs. W. J. Grant, Tom Wood, Mamie, Countess of Gosford, Innocente Pirola, Star of Waltham, Lady Ashtown, Alfred Colomb, Mrs. Cocher, Chas. Darwin, Ulster, Hugh Dickson, Souvenir de Pierre Notting, and Mrs. John Bateman. The 2nd prize was awarded to Messrs. R. HARKNESS & CO., Hitchin. 3rd, to Messrs. BEN. R. CANT & SONS, Colchester.

Forty distinct varieties, in triplets.—There being three blooms of each variety, each competitor had to furnish 120 blooms, so that the exhibits, which numbered four, occupied a considerable space and presented a very fine display. The best of the four exhibits was put up by Messrs. BEN. R. CANT & SONS, Colchester, the varieties including Mildred Grant (three fine blooms), Alfred Colomb, Mme. Jules Graveraux, Her Majesty (fine blooms, rather much blown), Golden Gate, Edward Andre, White Maman Cochet, Caroline Testout, and Bessie Brown. 2nd, Messrs. ALEX. DICKSON & SONS, Newtownards, Ireland, whose best examples were Walter Speed (new, of pale yellow colour), Dean Hole, Ulster, Hugh Dickson, Mrs. Myles Kennedy (of magnificent form and best shape of petal), and William Shean. 3rd, Messrs. D. PRIOR & SON, Myland Nursery, Colchester.

Forty-eight blooms, distinct.—This proved a good class, the blooms generally being of first-class quality, especially those in the 1st prize exhibit, which was shown by Messrs. J. BURELL & CO., Howe House Nursery, Cambridge. The choicer blooms were those following: J. B. Clark, Florence Pemberton, Gladys Harkness, Bessie Brown, Oberhoigartner Tercks, Ulrich Brunner, Mildred Grant, Lady Ashtown (a finely formed bloom), Maman Cochet, A. K. Williams, Mrs. E. Mawley, Mme. Philippe Rivote, Frau Karl Druschki, Mrs. T. Roosevelt, Muriel Grahame, Gustav Grunerwald, &c. 2nd, Messrs. G. & W. BURCH, Peterborough, who had Princess M. Merckertsky (a big flower with a fine centre), Her Majesty (grand bloom), Mildred Grant, Queen of Spain, Tom Wood (excellent), Duke of Erie, &c. 3rd, Mr. G. MOTTN, Canterbury, whose example of A. K. Williams won the Silver Medal offered for the best Rose other than H.T., Tea, or Noisette in the nurserymen's section.

Sixteen varieties, shown in triplets.—This proved an interesting class, and many beautiful blooms of well-known kinds were seen. The premier exhibit was displayed by Mr. H. DREW, Longworth, Faringdon, who had Bessie Brown, Mildred Grant, G. Harkness, Comtesse de Nadailac (a remarkably choice bloom), Hugh Dickson, G. Harkness, Dean Hole, and White Lady as his best flowers. The 2nd prize was awarded to Mr. C. TURNER, Slough.

Sixteen distinct varieties, three blooms of each.—This class for triplets proved a good one, for no fewer than seven exhibits were staged. Some first-class blooms were seen, especially in the 1st and 2nd prize groups, the former being staged by Messrs. G. & W. BURCH, Peterborough, and in which were seen notable examples of Caroline Testout, Mildred Grant, Ulrich Brunner, Papa Lambert, Gustave Pigneanu, Mme. Jules Graveraux (especially good), Her Majesty, &c. 2nd, Messrs. J. BURELL & CO., Howe House Nursery, Cambridge, with smaller blooms. There was a magnificent trio of Dean Hole in this collection. 3rd, Messrs. J. JEFFERIES & SON, Royal Nurseries, Cirencester.

TEA AND NOISETTE ROSES.

The chief class in this section was for 24 blooms of distinct varieties. There were four contestants, the 1st prize being won by Mr. A. E. PRINCE, Longworth, Faringdon, who was not far ahead of the 2nd prize winners, Messrs. B. R. CANT & SONS, Colchester. In Mr. PRINCE'S group we may enumerate Comtesse de Nadailac, Innocente Pirola, Maman Cochet, Mme. Jules Graveraux, Muriel Grahame, Mme. Cusin, Mrs. Ed. Mawley, Mme. J. Dupuy, and Souvenir de Pierre Notting as being especially fine. 3rd, Messrs. F. CANT & CO., Colchester.

Twelve blooms, distinct varieties.—Mr. J. R. MATTOCK, Headington, Oxford, was an easy 1st prize winner, his collection being especially good. He showed in grand style such fine varieties as Mme. J. Graveraux, Maman Cochet, Mme. Constant Soupert, White Maman Cochet, Empress of Russia, Innocente Pirola, Catherine Mermet, Medea, Boadicea (a splendid bloom), Cleopatra, Bridesmaid, and Muriel Grahame. 2nd, Messrs. PAUL & SON, Cheshunt. 3rd, Messrs. J. BURELL & CO.

Forteen distinct varieties, shown in triplets and staged in vases.—There was a marked contrast in the various groups, of which there were seven, some being poor and others remarkably

good. The finest collection was staged by Messrs. B. R. CANT & SONS, The Old Rose Gardens, Colchester, who put up a choice lot—Mme. Jules Graveraux, White Maman Cochet, Mrs. Ed. Mawley, Innocente Pirola, Mme. de Watteville, &c. 2nd, Mr. HENRY DREW, Longworth, Berks., with Mrs. Pierpont Morgan (a flower resembling the one named after Mme. Cusin), Maman Cochet, Medea, &c.

GROUPS OF ROSES.

This year the most important class was represented by two firms only, Messrs. HOBBS, LTD., Dereham, Norfolk, and Messrs. PAUL & SON, Cheshunt, Berks., who won in the order of their names. Messrs. HOBBS, LTD., had a pleasing group, principally of tall Rambling varieties, all well furnished with flowers. The best were Delight, Tauesendshön, Hiawatha, and Dorothy Perkins. The group was semi-circular in shape, and around the foreground were several pretty baskets of Roses on stands. The edging was formed of Ferns, *Isolespis gracilis*, &c. Messrs. PAUL & SON had greater variety in their group, and the blooms were very choice, but it had not quite so striking an effect as the one just described.

The class for a representative group of cut Roses occupying an area of 100 square feet, the blooms to be shown in glasses, vases, baskets, &c., but not in boxes, was of great importance, for most of the noted Rose firms entered. The class enabled groups such as are staged at some shows as non-competitive (but which here are not allowed to be displayed) and they required a very large amount of room for their staging. Mr. GEO. MOTTN, Canterbury, won the 1st prize with one of his characteristic displays, in which he forms large banks each of a few choice varieties, such as Frau Karl Druschki, Rev. Joseph Low, Liberty, Mrs. John Laing, &c., with an assortment of specimen blooms along the front. 2nd, Mr. F. M. BRADLEY, Church Street, Peterborough; and 3rd, Messrs. W. & G. BROWN, Peterborough.

ROSES IN VASES.

The class for twelve distinct varieties, not more than half the number to consist of Tea or Noisette Roses, was a notable class. Seven blooms of each variety were required, and the space was limited to 6 feet by 3 feet. Great praise must be accorded to Messrs. ALEX. DICKSON & SONS, Newtownards, Dublin, for their fine exhibit which won the 1st prize. They showed some magnificent blooms, on stout big stems and with foliage. Mildred Grant was shown superbly, also Bessie Brown, Dean Hole, Lord Derby, Ulster, Lady Ashtown, and Florence Pemberton. The adjoining exhibit, shown by Messrs. D. PRIOR & SON, was also of great merit, and it was given the 2nd prize. 3rd, Messrs. F. CANT & CO.

Another class for nine distinct varieties of Tea and Noisette Roses, also seven blooms in a vase, was contested by four growers. The premier award went to Mr. HENRY DREW, Faringdon, Berks., for small but highly refined blooms of Maman Cochet, Mme. Cusin (very choice), Muriel Grahame, White Maman Cochet, Souvenir d'un Ami, The Queen, Mrs. Stephen Treseder, &c. 2nd, Mr. JOHN MATTOCK, Oxford, for smaller blooms.

DECORATIVE ROSES IN VASES.

There were three classes for these Roses, and as each exhibit was staged on a separate table, they almost filled one of the tents. Almost universally there were three tiers, draped by some dark cloth material, and in every case they were arranged in vases. The schedule required foliage and shoots to show the habit of growth; exhibition Roses were excluded. Most of the blooms were drooping, and many faded from extreme heat. The chief class was for 36 distinct varieties, not fewer than three nor more than seven trusses of each variety being allowed. There were only two exhibitors, viz., Mr. J. MATTOCK and Messrs. PAUL & SON, who were awarded the 1st and 2nd prizes respectively. Mr. MATTOCK had Irish Glory (a beautiful single variety of a shade of red), Belle Fleur, Hebe's Lip (the pretty white blooms with golden centres remained fresh throughout the day), Mons. Paul Lede, Papillon, Gustave Regis, Bardou Job, Leucht-torn, &c.

Eighteen distinct varieties.—The blooms presented a sorry spectacle—most of them hung

withered over their receptacles. The 1st prize was given to MESSRS. W. SPOGNER & SON, Arthur's Bridge Nursery, Woking. Rubins, a Rambler variety after Crimson Rambler, was fine in this and several other groups; Helen, Gustave Regis (a big semi-double variety, creamy-white), Mrs. F. W. Flight, Lechtstern, and Tea Rambler are the more notable kinds shown. 2nd, Mr. C. TURNER, Slough, whose group could not have been more than a point or two below the 1st prize exhibit. 3rd, Mr. J. BARROW.

In another class, in which several types of Roses permitted in the other classes were excluded, the 1st prize was won by Mr. GEO. PRINCE, Oxford, and the 2nd by Messrs. G. COOLING & SONS, Bath.

quality, and, until the afternoon, were in the best condition. E. B. LINDSELL, Esq., Bearton, Hitchin, was 1st with exquisitely beautiful blooms of the largest size. Four of them were Irish Roses, viz.: Florence Pemberton, Alice Lindsell, Dean Hole, and Earl of Dufferin, together with Queen of Spain, Mme. J. Graveraux, Horace Vernet, Souvenir d'Elise, Countess of Oxford, Mrs. Mawley, Cleopatra, Countess of Waltham, Mrs. Jno. Bateman, Marie Baumann, Maman Cochet, and the white variety of this Rose, Fisher Holmes, Mme. Delville (a neat bloom of a deep pink tint), Souvenir de Pierre Notting, Her Majesty, Mrs. J. Laing, Alfred Colomb, and Oberhofgartner Tercks. The 2nd prize was awarded to the Rev. J. H. PEM-

The next important class was that for 24 distinct varieties, open to all amateurs irrespective of the number of plants they grow. A. TATE, Esq., Downside, Leatherhead, Surrey, won the 1st prize, his finest blooms being W. Shean, Mrs. T. Roosevelt, Florence Pemberton, Robert Scott, Ulster, Countess of Derby, 2nd, E. B. LINDSELL, Esq., with good blooms, but conspicuous for irregularity in size. The examples of Horace Vernet, Mildred Grant, and Bessie Brown were the finer.

The next class was for 12 blooms of distinct varieties in triplets, in which E. B. LINDSELL, Esq., took the 1st prize with a boxful of very fine blooms, among which we observed Dean Hole, Mildred Grant, Duches of Portland, White Maman Cochet, Bessie Brown, Florence Pemberton, &c.; 2nd, E. J. HOLLAND, Esq., Sutton, Surrey, with fine, large blooms of Tea and Hybrid Tea varieties. Excellent were Mildred Grant, Mr. T. Roosevelt, Mrs. J. Laing, Dean Hole, Florence Pemberton, and the bright pink variety Mrs. W. J. Grant.

Nine blooms of any Rose, except Teas or Noisettes, to be shown in three vases.—1st, F. DENNISON, Esq., with very large and perfect examples of Mildred Grant; 2nd, Dean Hole, as exhibited by G. A. HAMMOND, Esq., Cambrian House, Burgess Hill.

A class was provided for growers of fewer than 2,000 plants of varieties found in the lists of exhibition Roses in the Society's book of arrangements. The 1st prize for 24 blooms of distinct varieties was won by W. O. TIMES, Esq., Hitchin. We observed nothing of exceptional merit beyond the examples of Oberhofgartner Tercks, Ulrich Brunner, Mme. Jules Graveraux, and Mrs. J. Bateman; 2nd, T. B. GABRIELLE, Esq., Hart Hill, Woking.

Eighteen blooms of distinct varieties.—1st, G. SPEIGHT, Esq., Market Harborough, for fresh-looking blooms, even in size, the finer ones being Caroline Testout, J. B. Clark, W. Shean, Her Majesty, and Souvenir de Pierre Notting; 2nd, E. MAWLEY, Esq., Rosebank, Berkhamstead, who showed chiefly red and crimson varieties, such as Gustave Piganeau, J. B. Clark, Suzanne Marie Rodocanachi, Chas. Lefebvre, Alfred Colomb and Ulrich Brunner.

Eight distinct varieties, in triplets.—The 1st prize fell to G. SPEIGHT, Esq., for good blooms of practically the same varieties as he showed in the preceding competition; 2nd, Mrs. FORTESCUE, Dropmore, Maidenhead, with excellent blooms of Bessie Brown, Dean Hole, Lady Ash-ton, and Her Majesty.

The Grahame Memorial Prize was awarded to Dr. C. LAMPLOUGH, Kirkstall, Alverstoke, Hants, for 12 blooms of distinct varieties.

Several classes were open only to growers of fewer than 750 plants of exhibition varieties.

The best 12 varieties, distinct, were shown by W. UPTON, Esq., 16, Claremont Street, Leicester, who secured the Benjamin Cant Memorial Prize. He had good examples of Countess of Caledon, White Maman Cochet, J. B. Clark, Bessie Brown, &c.; 2nd, H. ROBINS, Esq., Margaretting, Ingatestone. Competition in this class was keen.

For the 12 best blooms, distinct, in a competition for the President's Prize, the competition was even keener than in the foregoing class, and the quality of the blooms extremely good in some instances. C. H. LESLIE, Esq., Epcombe, Hertsfordbury, Herts, won the 1st prize. He showed excellent blooms of Florence Pemberton, Mildred Grant, Lady M. Beauclerc, Mme. J. Graveraux, and Maman Cochet; 2nd, Rev. H. S. ARKWRIGHT, Binfield Rectory, Bracknell, with notable examples of François Michelin, Comtesse de Nadaillac, H. Vernet, and Dean Hole.

In a class for six blooms, distinct, open to growers of fewer than 200 plants, the 1st prize was awarded to C. G. BARON, Esq., Charmwood, The Avenue, Hitchin.

W. BENTLEY, Esq., 21, Lombard Street, E.C., was 1st in a class for six blooms, in not fewer than four varieties; 2nd, H. F. MATHEWS, Esq., Berkley House, Stevenage.

A. E. CLARK, The Hurst, Mottingham, Iltham, was the winner of the 1st prize in a class confined to suburban growers with White Maman Cochet, Frau Karl Druschli, Mrs. J. Laing, Killarney, &c.

A class was set apart for amateurs who have not won a champion challenge trophy or the 1st prize in the extra class for amateurs. This was

FIG 14.—ROSE BLUSH RAMBLER TRAINED OVER A RUSTIC ARCH: COLOUR OF FLOWERS BLUSH PINK, PALER IN THE CENTRES. (See p. 31.)

MEDALS FOR PREMIER BLOOMS.

The best Hybrid Perpetual Rose was adjudged to be the bloom of A. K. Williams, shown by Mr. GEO. MOUNT; the best Hybrid Tea, William Shean, shown by Messrs. ALEX. DICKSON & SONS; and the best Tea Rose, Mrs. Miles Kennedy, shown by Messrs. G. COOLING & SONS.

AMATEUR CLASSES.

The blooms shown in the premier class for 36 Roses, distinct varieties, were of very fine

quality, Havering-atte-Bower, Essex, for a beautiful lot of blooms, a trifle lacking in size. We observed in the back row blooms of Mrs. Theo. Roosevelt, Lohengrin, Ulrich Brunner, all of them of noteworthy size; others were Mildred Grant, Charles Lefebvre, A. K. Williams, Marie Baumann, Caroline Testout, and Alice Lindsell. 3rd, F. DENNISON, Esq., Rosecroft, Kenilworth, his boxes containing among others fine blooms of Bessie Brown, Gustave Piganeau, Ulster, Ulrich Brunner, Helen Keller, J. B. Clark, Dean Hole. Competition was in this class very close.

[Photograph by F. Mason Good.]

a competition in which 24 blooms of distinct varieties were required. MAILLON WILLELE, Esq., was the successful exhibitor, the prize including a piece of plate.

In a class for 12 blooms of distinct varieties, open to all amateurs, E. J. HOLLAND, Esq., Sutton, was awarded the 1st prize, and E. B. LINDSELL, Esq., the 2nd prize.

In the Tea and Noisette trophy class for 18 blooms, distinct, the 1st prize and trophy was taken by ALEXANDER HILL GRAY, Esq., who had choice blooms of Mme. C. Soufert, Comtesse de Nadaillac and Souvenir de Pierre Notting.

MEDALS FOR SPECIMEN BLOOMS.

The best Hybrid Perpetual Rose was a bloom of Her Majesty shown by Mr. E. J. HOLLAND; the best Hybrid Tea Dean Hole shown by Mr. E. B. LINDSELL; and the best Tea, a specimen of White Manan Cochet, in Mr. CONWAY JONES' exhibit.

GOLD MEDAL NOVELTIES.

Gold medals were awarded to the two new varieties described below.

Mrs. J. Campbell Hall.—A medium-sized bloom of the Tea section, having creamy tinged with rose. Shown by Dr. J. C. HALL, Rowantree, Monaghan.

Mita Weldon.—This variety is also of the Tea section, and is creamy-white with just a suspicion of rose. Shown by Messrs. ALEX. DICKSON & SONS.

LINNEAN SOCIETY.

DARWIN-WALLACE CELEBRATION.

JULY 1.—On this date the Linnean Society celebrated the 50th anniversary of the reading of the joint essay by Charles Robert Darwin and Alfred Russel Wallace, entitled, "On the Tendency of Species to form Varieties; and on the Origin of Species and Species by Natural Means of Selection," which preceded by 16 months the issue of the classical "Origin of Species."

In the afternoon a special meeting was held at the Institution of Civil Engineers, by permission of the Council of that Institution, when a gold copy of a specially-struck medal, bearing the portrait of Darwin on one side and that of Wallace on the other, was presented to the surviving author, Dr. Wallace, who spoke of his share as due to a "dash of insight." His preliminary paper was written and sent home within a week, whilst Darwin had been patiently accumulating facts for 20 years in support of the same theory, conceived so many years back. Sir Joseph Hooker, O.M., G.C.S.I., was also present, and, on receiving a silver copy of the medal, read an account of the actual events which preceded the reading of the essay in greater fulness than has hitherto been published. The following eminent biologists also received silver medals (the gold copy being bestowed upon the surviving co-author):—Professors Haeckel and Weismann, which were received for them by the Secretary of the German Embassy; Herr von Bethmann-Hollweg, Professor Strasburger, Dr. Francis Galton, and Professor Sir Ray Lankester, who brought the series of replies to a brilliant close by an admirable address, in which he said: "Several able observers and experimenters have set themselves the task of improving, if possible, the theoretical structure raised by Darwin and Wallace. One of the earliest of these was Dr. George Romanes, whose views on physiological selection and on instinct were communicated by him to this Society, but have not successfully held the field. Later we have had the doctrine of mutation advocated on a somewhat unsatisfactory basis of fact by Professor De Vries, and the resuscitation and development of the observations and conclusions of the Abbé Mendel on heredity. These have all been the outcome of earnest and serious work, and have led, and are leading, to more complete knowledge of the facts of heredity and variation. But I venture to express the opinion that they have none of them resulted in any serious modification of the great doctrine submitted to the Linnean Society on July 1st, 1859."

Next followed the presentation and addresses from universities and societies, with the Royal Academy of Science, Stockholm, specially invited; these had as spokesmen Dr. Francis Darwin, Sir W. T. Thiselton-Dyer, Professor Lönn-

berg, and Sir Archibald Geikie. The last speaker was Lord Avebury, who gave an account of his long acquaintance with Darwin, from 1842 to his death.

The Fellows gave a dinner at Prince's Restaurant to the medalists and foreign guests, those present being Professor Strasburger, Dr. Galton, and Sir Ray Lankester as medalists; and Professors Haeckel, Warming, Jørgensen, and Lönnberg as foreign guests.

A reception in the rooms of the society followed, amongst the objects shown being natural and artificial hybrids of *Odontoglossum*, and an extensive display of *Lepidoptera* from the Hope collection, Oxford, to show mimicry, several variations, and protective resemblances.

SOUTHAMPTON HORTICULTURAL.

JUNE 30, JULY 1.—The summer show of the above Society was held, as usual, on the County Cricket Ground on the foregoing dates, and in point of quality the exhibition was equal in merit to the average of previous shows.

The principal class for Roses was for 48 distinct blooms, and this brought six entries. Messrs. FRANK AXON & CO., Baiswick Nurseries, Colchester, won the 1st prize with fresh-shaped examples, although rather small, of J. B. Clark, Florence Pemberton, Mme. J. Gravereaux, Dean Hole, Mildred Grant, Lady Ashton, Victor Hugo, Hugh Dickson, and Lady M. Beaulieu, &c. Messrs. B. R. CANT & SONS, Colchester, won the 2nd prize.

In the Tea or Noisette class for 12 distinct varieties, there were many fine blooms staged by five exhibitors. Messrs. B. CANT & SONS won with typical examples of Cleopatra, The Brule, Boadicea, Mrs. M. Kennedy, Mrs. E. Mawley, Ernest Metz, and Mme. J. Gravereaux; 2nd, Mr. DREW.

Messrs. B. CANT & SONS thus won the President's Cup with a total of six points in the three classes. The best six blooms of a dark variety were shown by Messrs. D. PRIOR & SONS, Colchester, who had J. B. Clark in fair condition. Messrs. F. CANT & CO. secured a similar position for any light variety with Mildred Grant.

The premier bloom in the show was one of Mildred Grant staged by Mr. DREW, the premier Tea was Mme. J. Gravereaux, belonging to Messrs. B. CANT & SONS.

Mr. R. Neville, gardener to F. W. FLIGHT, Esq., Costantines, Twyford, Winchester, was 1st for 18 distinct varieties. Dr. CHARLES LAMPOUGI, Kirkstall, Alverstone, was a good 2nd. The last-named exhibitor was 1st for six triplets.

Sweet Peas were a notable feature of the show, so numerous were they displayed. No fewer than 20 growers staged in the class for six bunches, the prizes being given by Messrs. TOOGOOD & SONS, Southampton.

Hardy border flowers were finely staged. Messrs. LAMBURN, The Nurseries, Shirley, Southampton, won the premier prize in the class for 12 bunches.

Fruit was poorly represented. Mr. Foskett, gardener to Mrs. LINDELL, New Milton, had the best black Grapes, but vegetables were numerous and good. Mr. BECKETT, Alesham House, Elstree, won easily Messrs. Sutton & Sons' 1st prize for six dishes with examples of high-class produce.

Mr. G. Ellwood, gardener to W. H. MYERS, Esq., Swannore House, Bishop's Waltham, won with very fine examples the premier prize in the class provided by Messrs. Toogood and Sons, Webb and Sons, and Carter and Co.

NON-COMPETITIVE EXHIBITS.

A Gold Medal was awarded to Messrs. TOOGOOD & SONS for a magnificent collection of Sweet Peas. A similar award was given Mr. E. WILKS, The Nurseries, Winchester Road, Southampton, for plants, cut flowers, and floral work, including a fine display of early-flowering *Gladioli*. Messrs. ROGERS & SON, Southampton, had a pleasing exhibit of Roses in pots, mainly of the Wichuraiana type. Messrs. LAMBURN had Pinks in great variety, Gaillardias, and a considerable assortment of Hardy cut flowers. Mr. GODFREY, Exmouth Nurseries, had a fine batch of *Solanum Wendlandii* freely flowered in pots; these, with *Pelargoniums*, *Poppies*, &c., made a pleasing exhibit. Mr. C. W. BREAMORE, Winchester, had Sweet Peas.

ANSWERS TO CORRESPONDENTS.

AGARIC, *E. S. S.* Possibly *Flammula gymnopoda*, Fr., but too old and decayed for accurate determination.

APPLES INFESTED WITH GRUBS: *R. H. B.* The damage has been caused by the grub of the Codlin moth (*Carpocapsa pomonella*).

BEGONIA RUST: *W.* The trouble is caused by a mite, and the best remedy is dipping the foliage in tobacco water. If the plants are very badly affected, destroy them by burning and start again with clean stock.

GRAPES DISEASED: *F. H. M.* The berries are affected with the spot disease. See reply to *H. Hubbard* in the last issue, p. 20.

GUMMING IN PLUMS: *J. H.* Gummosis of stone fruit is due, according to recent researches, to a variety of causes. Bacteria, fungi, and cultural conditions contribute to cause gumming. It is impossible to say from the few Plums received to what cause the trouble is due in your case. We find no fungi or bacteria, but from your description we gather that the trees start gumming about this time of year. We advise you to give the trees a good watering during dry weather, and apply a liberal dressing of lime. Transplant the trees in autumn into a newly-prepared border. Severe pruning frequently causes gummosis.

NAMES OF PLANTS: *T. O. I.*, *Crataegus dipelliana*. This tree will probably flower if you prune its roots lightly in autumn. 2, *Crataegus Crugalli* var. *pumifolia*—*John Kimout*. 3, *Vicia villosa*—*H. T. N.* 7, *Lycium chalcadonica*; 8, *Alströméria hemantha*; 9, *Lilium Martagon album*; 10, *Anchusa italica*; 11, *Diclianthus albus var. purpureus*; 12, *Nerium Oleander roseum plenum*—*D. D. S.* Probably *Lycynis dioica* var. *thore pleno*—*A. H. D.* *Helianthemum vulgare* var. *ochroleucum*—*A. B. H.* 1, *Allium spheroccephalum*; 2, *Wahlenbergia tenuifolia*; 3, *Iberis Tenoreana*; 4, *Solidago virgaurea*; 5, *Helianthus ruber* var. *Major*; *H. Bennett*. Appears to be a double variety of *Ranunculus asiaticus*, but it is difficult to identify such a specimen.—*L. G. P.* *Gilia coronopifolia*—*T. H.* *Dendrobium aduncum*—*F. M.* 1, *Lastrea dilatata*; 2, *Allosorus crispus*; 3, *Asplenium trichomanes*; 4, *Asplenium viride*—*Falconer*. 1, *Odontoglossum Lindleyanum*; 2, *Odontoglossum bianicum*; 3, *Oncidium barbatum*.

NECLARINES: *P. B.* The fruits are rotted by *Botrytis cinerea*, a mould disastrous to pulpy fruits. Collect and burn the diseased fruits as soon as the disease appears, and spray the rest with the Bordeaux mixture as a preventive.

ONION SETS ROTTEN TO SEED: *R. M.* Your enquiry does not make it clear whether you refer to sets of Potato or Underground Onions, which, like Shallots, are increased by planting in the spring the smaller bulbs which have been saved from the clusters of bulbs grown in the previous year. If these are meant, it is not common for them to bolt to flower, but if the largest bulbs are so planted, they will sometimes do so. If you refer to small bulbs raised from seeds sown in the summer, such bulbs being of some large growing variety, but having ripened off whilst quite small, and been stored for the winter and planted in the spring to develop into large bulbs during the summer, they may often bolt to flower. In order to secure very fine bulbs, sow seeds of *Ailsa Craig* in August, which will give green plants to stand the winter, and plant out thinly in good soil in April, or seeds of the same variety may be sown in a shallow pan or box under glass in February to plant out in May.

PEA FOR NAMING: *G. T.* The variety is known as the Mummy or Crown Pea. See fig. 45, p. 120, in the issue for August 10, 1907.

TOMATO LEAVES: *F. H. P.* The only mould found on your Tomato leaves is the common *Aspergillus glaucus*, growing on dead spots. There is not the slightest trace of the ordinary Tomato rust.

HUNGARIAN AGRICULTURE AND HORTICULTURE.

THESE twin industries, the greater including the lesser, of that great country forming the major portion of the Austrian dominions of the present day, are illustrated in a remarkable manner by the exhibition now being held at Earl's Court. It may be interesting to Englishmen who have, in general, very little knowledge of the country and its people, and little acquaintance with its history beyond the names of F. Kossuth and other Hungarian patriots of '48. Hungary lies off the general route of travellers, and as a consequence its various peoples, their manners and customs, as well as the conditions of life, the status of the country in the arts of farming and gardening are but superficially known to most foreigners. Again, the language offers considerable difficulty to the traveller, although it is one which is being gradually altered for the better, every boy and girl in the better class schools being obliged to learn a second language, and usually this on the

west side of the country is German, Italian or French, and south and east Turkish, Polish, Russian, or some other Slavonic language. This all helps the visitor coming from over the frontier, enabling him to get about in country districts with the minimum of trouble.

Under the patriotic Magyar influence much has been done in advancing farming in all its branches by means of research stations, both royal and provincial, established in many of the more important committats (counties), and improvements are being carried out in stock breeding, sheep farming, horse breeding, and poultry raising, dairying, including that carried on by associated villages; also the manufacture of sheep's milk cheese, a favourite food with the people. The cultivation of Wheat is perhaps the most important branch of farming, and it may be said that Hungarian wheat flour is held in high esteem in our own country for making the finer kinds of bread and pastry; and it is almost indispensable for these purposes. Unlike the Germans and Austrians, who consume large quantities of Rye flour, the Hungarians of all classes, even the poorest, will eat only wheat flour of some kind, the cheaper being ground together very finely with the bran. This is a fact that deserves to be brought home to our own people, the entire product being more nutritious than the most perfectly white flour that we consume. Fruit growing is an extensive industry; Apples, Pears, Plums and Grapes being the chief crops in all parts of the country, excepting, perhaps, in the south bordering on Slavonia, and in the north and east.

One of the most useful fruits is the Plum; and much of this fleeting crop which, from its nature, cannot be stored, is dried Prune fashion, or bottled for compotes, or it is made into a conserve or jam without sugar being added, and is then called *borvidal*, forming an article of universal consumption by the peasantry. By a long course of boiling it is converted into a dark coloured mass of very close consistency, that will keep for years without deterioration.

The Apples mostly grown are of English, French, or German origin, the only Hungarian varieties of note being Szerosika, much grown in Southern Hungary, and Faros, a large fruit capable of keeping from December to March. Pears are almost entirely French or English in origin, and the best fruit nurseries have most of the finer varieties on sale. Standards of the Apple fetch 1s. to 1s. 6d. per tree, dwarfs and pyramids 8d. to 10d.

Plums include all the best French and English varieties, and the nursery prices are a little higher than those for Apples. A great favourite is Berzenozy (Muskatally szilva), a very excellent Plum from Upper Hungary. Cherries are largely cultivated in certain counties, and nearly all are of foreign origin. Apricots and Peaches find a place among the vines, needing no protection, excepting in the north, where the frosts are usually very severe. The Orozvari is a very fine Apricot, ripening in August. The varieties of the Peach are mostly French or English, and in the best gardens very fine fruits are obtained.

The same remarks hold good for Nectarines. Grapes for wine manufacture and consumption, in my list of the varieties grown in the nursery of Graf Henkel von Donnermark at Carlburg, near Pressburg (Pozony), number 241, and the chief of these are German, French, Italian or Spanish and a few of English origin. The true Hungarian varieties are the Fekete, Chasselas of Hungary, with Parsley-like leaves, white and gold—all are excellent; Keckskecsesfeher (*feher* meaning white); Nagy szemű szolo, a berry of great size; and Tokai, large, early and black. As compared with our prices for vines, they are sold at very cheap rates.

It is now appropriate to turn to the objects relating to gardening and farming disclosed in the Dual Hall at the exhibition. An exhibit near the entrance to the hall consists of vines and wines from Tokai, a hill celebrated for its wines all over the world, which, however, are said to be bought up annually by the rulers of all European countries; less important individuals having to be contented with wine under the name of Tokai, which may be the produce of the neighbouring vineyards. I saw only the labelled bottles of famous brands, such as Rajnai Riesling, Boughadivores (black), Tokai borovidik, Carbinet, Sashegy, and a so-called Burgundy, in one, two and three litre bottles, the latter too much, as I should suppose, for the "one-bottle" man at a sitting. There alongside the wine exhibit there were observed specimens of methods of pruning the vine (1) with three long shoots left, which were drawn together so as to form two circles, the loose ends being fastened to a stake; (2) the short-spur method, leaving two shoots, the future shoots from these spurs being bound to a stake as they extend their growth. The palmette form of training vines was illustrated by neat little models, with vines trained over the trellises horizontally and obliquely. This seemed a very practical method both for vines and for several other kinds of fruit.

Examples of Grapes imitated in wax, red, black, amber, and white, were noted, these being modelled from vineyard fruits. There are shown packing boxes for the transmission of Grapes to a distance, these being 9 inches square and 4 inches deep, fastened with a certain kind of coloured string as used by postal or railway direction; and peeled willow baskets, very light, clean looking, and easily handled and packed. Models of various diseases of Grapes, not unknown to cultivators in our own country, are exhibited in airtight cylinders of glass, the bunches hung back to back on strips of cardboard. A map of a vineyard at the vine dressers' school at Pressburg illustrates the manner of planting plots of varieties of Grape vines. Another map shows school vineyards at Tarczal, and at Eger. An interesting coloured map of the whole country was noted, showing the districts in which the climate permits of the cultivation of the Grape vine out-of-doors.

There is a pretty collection of models of training the vine, such as circles within a circle, vases, arbours, globe on globe, double

erect cordons, and cordons in quadrangular fashion, oblique cordons trained with four shoots proceeding from each vine, and vines in cylinder shape attached to four squared stakes.

There are photographic views of various Hungarian parks, showing much bold planting, large stretches of lawn, and well-kept paths. The chief difficulties that have to be overcome in Hungary are the maintenance of a good sward under the prevailing conditions of the hot summers, involving the saturation of the soil twice or thrice a week, when probably water is scarce, or lacking in the neighbourhood; and the heavy snowfall in some parts which lies from November till late in March kills many of the grasses.

Coloured diagrams of fruits and nuts grown in the country, showing their areas of distribution throughout the provinces, are exhibited. These illustrations show the fruit inside a circle, and, being coloured, enable one at a glance to see whether green, purple, rose coloured and white Grapes are those chiefly cultivated. In the case of other fruits, the illustrations are equally helpful. For example, one observes at a glance that the Plum is largely grown at Nytra and Bars in the west, and in the east at Ugoesa, Marmaros, Hunyad and Szilagy. Apples and Pears grow everywhere, as do Walnuts. The eastern Comitatus (counties) are almost destitute of Cherries, but I was not enabled to obtain the reason for this.

Another coloured map shows in what districts to look for the chief kinds of vegetables. Silk culture is being greatly fostered in Hungary, and illustrations of many silk-weaving mills are to be seen; as likewise thousands of cocoons of the silkworm, presumably containing the killed insect, and a boxful of skeins of spun silk of a beautiful golden tint.

Tobacco cultivation is shown as carried on at Debreczin, in the Royal Experimental Station at that important town. Methods of sorting, bundling, drying and curing are displayed, and are illustrated by numerous photographs. Tobacco cultivation is pretty widely spread in the country, and an agreeable kind of "weed" is produced; moreover, it costs less than 8d. per pound, a consideration certainly when a properly filled pipe holds nearly one ounce.

The production of milk is well looked after by the authorities, both local and governmental, as is evident from a large scale map, from which it appears that the village milk federations are chiefly concentrated in the N.W., W., S.W., and S. of the country. Samples of milk and milk products are shown in bottles and jars hermetically sealed. The exports of milk, and products obtained from milk, seemed to have reached their apogee in 1900, sheep's milk cheese being highest in that year, that of ordinary cheese in 1903, and superior cheese in 1904. Hungary possesses, at the least, one Royal Seed Testing Station. Here, for example, they take 3 kilograms from each sack of samples to test for Dodder.

An instrument is shown which determines the degree of moisture present in samples of seeds. There is exhibited a kind of lead seal for fixing on sacks of seeds, invented by Stephen Junkunze; also a tool for affixing them, a patent (Gallauner's).

The Government Bee Farm at Gödöllő is

shown in a photograph. The honey production in 1886 had a value of 300,000 kronen, but in 1899 it amounted to several times this sum and the value of beeswax has increased proportionately with the honey.

There are wooden hives and straw bee skeps, and a bee shed, as well as samples of run honey, and of wax, in square lumps, as sold at the shops. The various implements used in the apiary should be of great interest to the beekeeper, and appear to be far more extensive than with us.

The agricultural seed department is well worth inspection, consisting, as it does, of the more important grains and other field crops and seeds of noxious weeds. These are shown in glass cylinders, with the names of the plants attached, making inspection an easy matter for the farmer and student.

An easily understood map of the entire country was noted. On this each Comitatus con-

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM "QUEEN ALEXANDRA" VAR. CRAWSHAYANUM.

This beautiful hybrid *Odontoglossum* (see fig. 15) was raised by de B. Crawshay, Esq., from *O. triumphans* × *O. Harryanum*. In every point, including shape, size, substance and colouring, the flower possesses great merit, and the plant was granted a First-Class Certificate by the Orchid Committee of the Royal Horticultural Society when brought before them on June 9 last. The sepals and petals are yellow, but this is heavily blotched with deep purple-brown markings, so that the ground colour is almost obscured. The front of the lip is white, the remaining part being prettily marked with rose-purple.

DENDROBIUM HERCOGLOSSUM.

SPRAYS of this pretty species are sent from the collection of G. W. Jessop, Esq., Cliffe Cottage, Rawdon, Leeds (gr. Mr. Wilkinson), who calls

FIG. 15.—*ODONTOGLOSSUM* "QUEEN ALEXANDRA" VAR. *CRAWSHAYANUM*: COLOUR PURPLE-BROWN ON A YELLOW GROUND, LIP MARKED WITH ROSE-PURPLE.

tains a circle, within which are indicated by differently coloured segments the areas under meadow, forest, arable and gardens, vineyards, willow plantations, reeds and sterile land. The largest area is under the plough, then comes forest land, then meadow, and lastly that devoted to vineyards. Of Hops there were observed about 50 different samples from many parts of the country, in colour and size equal to the best Kent productions. The maps of temperatures for the whole country at four different seasons afford an interesting study. The illustrations of diseases affecting fruit trees, grain plants, Beans, &c., are doubtless of much use to cultivators in general, and also in teaching the older school children to recognise these pests. I noticed examples of *Ustilago* on Wheat, of *Puccinia graminis* on Berberis, *Claviceps purpurea* and several other fungal pests. *F. Moore*.

attention to the plant's floriferous habit. The racemes, which are about an inch long, bear three to five flowers, each three-quarters of an inch across. They are white tinged with rose, all the segments being furnished with short, hook-like tips; the rounded labellum is white with an acute beaked apex, and the anther-cap is purple. The flowers are freely produced and are very attractive. The species formed an interesting feature in the remarkable collection of rare botanical Orchids shown by Sir Trevor Lawrence, Bart., gr. Mr. W. H. White, at the Temple Flower Show, 1900, when a Botanical Certificate was awarded to it.

BARTHOLINA PECTINATA.

THE well-flowered plant of this pretty South African terrestrial Orchid, shown in their group at Holland House on July 8 by Messrs. Charlesworth & Co., Heaton, Bradford, seems to indicate that this species is not so difficult to cultivate as some growers who have had less pleasant experience with it might imagine. Those who have

failed to grow it satisfactorily have commonly done so through keeping it in a too moist and too warm temperature. There is a large class of small-growing South African terrestrial Orchids, including several species of *Holobolix*, *Disa*, *Satyrion*, &c., which, although they are sometimes seen in great beauty, as in the present instance, are generally regarded as very difficult subjects to manage. The grassy-leaved and many other *Disas*, the *Satyrions*, *Bartholinas*, and others which do not generally thrive in the Orchid house, when seen in good condition, have invariably been grown as cold greenhouse or frame plants, and potted in sandy peat or other gritty soil, and not in the material usually used for Orchids. The *Bartholina* shown by Messrs. Charlesworth had, with others, been grown on a narrow shelf near the glass of the roof in a cold house, and nearly every little tuber had produced its curious fleshy leaf and hairy scape, each with a white flower prettily tinted with blue, the labellum being comb-like in form. After the flowers fade, this species and others of a similar nature require to be dried off and kept very cool until springtime comes again, when they must be repotted and started into growth afresh. It should be remembered that the dwarfier the stature of the species the greater the necessity for keeping it well up to the glass of the roof of the greenhouse or frame in which it is housed. J. O.B.

VANDA PUMILA.

At fig. 16 we reproduce a flower of this interesting and rare species, a native of the Sikkim Hills, where it occurs at an altitude of about 2,000 feet. As may be suspected from the picture of the flower, which is reproduced at a natural size, the plant is very dwarf and generally small in its parts, resembling in appearance *V. alpina* and *V. cristata*. The flowers, which are produced in pairs, are cream-white with purple lines on the upper side of the ridged labellum, which differs from that of *V. cristata* in the absence of diverging horns at the apex. The plant has no great value as a decorative subject, but it is interesting from a botanical point of view, and was awarded a Botanical Certificate by the Orchid Committee of the Royal Horticultural Society when exhibited by Messrs. Moore, Ltd., Rawdon, at the meeting held on June 23 last.

NOTES FROM RYDE.

THOSE readers of the *Gardeners' Chronicle* who in the past have visited the garden of the late Rev. H. Ewbank, at the Old Parsonage, Ryde, will doubtless recall some of the many plants then grown in that interesting collection. The fine example of *Poinciana* (*Casalpinia*, *Gilhesii*) which in its best days was a small tree some 18 feet through, is now in a rapid decline, while a large plant of *P. (C.) japonica*, with its elegant, fern-like leafage, would easily reach to 30 feet across did space permit, but I do not think it has flowered as yet. On the walls, or near them, such things as *Indigofera*, *Fabiana imbricata*, several feet high, the brae-hes clothed with dense masses of the pure white, tubular-shaped blossoms; *Lonicera Hildebrandiana*, not so large or so healthy as in the past, but still capable of flowering well; *Rosa gigantea*, cramped for room at present, and yielding but a few flowers each year, full of vigour and making splendid growth; a large example of *Melianthus major*, *Rosa bracteata*; and *Cistuses* in handsome bushes afford much beauty. Among interesting and beautiful species flowering early in June were the *Tamarix*, the bushes of which were laden with pale-pink blossoms forming graceful sprays, and the curious, green-bronze flowers of *Cortaria japonica*, to be later succeeded by amber-yellow fruits. A fine specimen of this was more than 5 feet high. A pair of well-flowered evergreen shrubs were to be seen

in *Pittosporum Tobira*, and *Rhaphiolepis ovata*, both of which are quite hardy in this garden. The *Pittosporum* has pure white flowers in clustered umbels, and smooth, obovate, coriaceous leaves, the blossoms as strongly fragrant as the *Gardenia*, while the *Rhaphiolepis* is a sturdy bush of 2½ feet high, and has clusters of white, elegantly-formed blossoms, not unlike those of *Kalmia* in form. A set of distinct species of *Rubus* include *R. deliciosus* of 6 feet high and through, *R. nutkanus*, herbaceous in its habit of growth, and *R. australis*, a most distinct species of miniature bramble-like habit with leaves not unlike those of the true *Smitax*, but longer and more pointed.

The pride of the garden, however, to my mind, was the handsome trees of *Abutilon vitifolium*, with hundreds of expanded blossoms and thousands of buds to maintain a succession for weeks to come. Of this glorious species there are apparently two varieties here, the one having blossoms of the palest sky-blue suffused with white, the other having blossoms coloured a pale mauve of most exquisite tone, the plants growing 12 feet high, with an expanse of flowering branches extending to a score of feet, bearing handsome, saucer-shaped blossoms of 3 inches across in their countless numbers constituted a floral feast such as is rarely seen. The *Abutilons* are grown without the least protection.

Another notable subject is a very handsome plant of *Tricuspidaria lanceolata*, a well-grown specimen, some 10 feet or so high, and not less than 15 feet in diameter. At

FIG. 16.—VANDA PUMILA: FLOWERS WHITE WITH PURPLE MARKINGS ON THE LABELLUM.

the present time this handsome bush—reputed to be one of the finest in the island—was ornamented by many thousands of the hanging, crimson-scarlet flower buds. Not only is this fine example in perfect health, but it carries each year a huge crop of blossoms, ripens seeds, and, continuing to grow faster than ever before, demonstrates the fact that it is perfectly content with its lot. It is growing in a somewhat sheltered corner of this exposed garden, and each year in winter a canvas screen is rolled over it during severe weather.

Eucryphia, *Edwardsia*, *Carpenteria*, *Romneya*, *Camellia*, *Hedychium*, *Agapanthus*, and the like are all to be found in the open garden, and the giant clumps of *Cinnamum Powellii* are things to admire. *Gerbera Jamesonii* is a perfectly reliable perennial without protection, and thrives well in a bed of very sandy soil, the brilliant vermilion crimson of flower heads, borne by the score, rendering it a conspicuous feature when in bloom. *Yucca baccata*, a somewhat rare species, was promising a spike of its flowers, and the same clump flowered last year. A large bush of *Diospyros Kaki* grows apace, but has not, I believe, as yet borne fruit, while in a state of rapid decline is a *Pavonia imperialis* 30 feet high and wide.

The large collection of lilies includes many good kinds; an almost complete set of the *Regelia cyclus* hybrids, and a few of the oncology group, for the cultivation of which latter group this garden was once famous. Such things as *Iris tinigiana*, *Belladonna Lilies*, *Sterbergias*, and *Tropaeolum polyphyllum* grow with freedom, while *Anemone palmata alba* and *Glaucolus Saundersii* are comparative

weeds. Of the smaller-growing plants there is a large number, while the Misses Ewbank are using their best endeavours to keep the memory of their late father green by continuing to grow and care for the plants he loved so well. E. H. Jenkins

THE FIGHT AGAINST WEEDS.

ALL cultivators, whether of gardens or of more extensive farms and plantations, have to wage war against plants which, appearing in places where they are not desired, are commonly termed weeds. A weed may be a plant of great beauty or even utility in its proper sphere, but when it persists in flourishing in places where it is not wanted it becomes, from the grower's point of view, a weed. An excellent example is the handsome Water Hyacinth (*Eichornia crassipes*), often cultivated with great care in our greenhouses for the sake of its beautiful blue flowers, but in parts of Australia, Java, and Florida it has become a veritable pest, blocking waterways and impeding navigation. Similarly in Ceylon, open spaces along the sides of roads, abandoned estates, and other areas have been over-run by the *Lantana*, also a valued hothouse plant in this country for the sake of its Verbenalike heads of orange-red flowers. The *Lantana*, although so successful in competing with some of the Ceylon native plants, is in its turn having to give way before the showy *Tithonia diversifolia*, a plant with flowers closely resembling some of the Sunflowers. Both the *Lantana* and the *Tithonia* are South American plants, and the secret of their success seems to have been that they were better adapted for colonising and holding open ground than the native woodland plants, and consequently where cleared areas were left after the destruction of the forest, they were easy winners in the race for possession. The successful colonisation of alien plants is even more marked in New Zealand, where in some parts of the country the dominant plants are not natives at all, but introductions which have actually succeeded in ousting the former possessors. Mr. Cheeseman, the Government botanist, in his comparatively recent work on the New Zealand flora, estimates that no fewer than 600 plants, aliens mostly of European origin, are naturalised in the country, and in some localities the native flora has been almost entirely supplanted.

Whether these introduced plants are mainly restricted to waste land, or are succeeding in establishing a position for themselves amongst the wild plants of the country, the matter presents a problem of great botanical interest for anyone on the spot to determine, if possible, exactly to what characteristics they owe their success. If, however, the aliens find a congenial home amongst cultivated crops, and cause the trouble and expense which, as is well known, so many weeds do, then the matter becomes more than an interesting biological study, and steps have to be taken to wage war on the pest and to prevent them from overpowering the more valuable plants which are less adapted for existence. This aspect of the case is well recognised in Great Britain, where recently the Board of Agriculture has issued in its admirable leaflet series several publications dealing with weeds, giving useful advice for their extermination. To those unfamiliar with these leaflets we might add that they can be obtained free on application to the Secretary of the Board at Whitehall. In Canada the conditions are very favourable to the introduction of new weeds. Some, doubtless, introduced by immigrants; others, already in the country, become transported to new areas with crops and other farm produce, or are distributed by normal natural agencies such as wind, running water, and animals. Localizable losses are sustained by farmers on account of this prevalence of noxious weeds, and serious

has the matter become, that the departments of agriculture are taking active steps and incurring considerable expenditure in their efforts to aid the cultivator. The Dominion Department of Agriculture maintains a special Seed Branch, which has recently produced a large quarto publication entitled *The Farm Weeds of Canada*. This contains some 60 beautifully-coloured life-size plates of the chief weeds of the Dominion and their seeds. Copies of this handsome volume are distributed free to all applicants. Coloured drawings are also supplied free to rural schools, so that every opportunity is given for Canadian farmers and their families to become familiar with the appearance of their foes, many of which are of European origin. In addition, the letterpress gives full particulars as to the best means of exterminating each weed. The same department has the duty of enforcing the Seed Control Act, which fixes a standard in respect to purity and vitality of seed, and affords to cultivators protection against the introduction of noxious weeds on their land.

Official activities are not limited to prevention. To take an example in Canada, the great province of Alberta is divided up into some 50 districts, to each of which a weed inspector is allocated who, amongst his duties, inspects farms, and, if necessary, has power to order the destruction of crops if badly infested with noxious weeds. Unoccupied farms are similarly cleared of weeds at the owner's expense. These thorough-going measures to exterminate weeds are worthy of every success, because in many countries it is the regrettable absence of co-operation which makes the fight against the invaders so hopeless. It is of little use for one man to spend time and trouble in ridding his land of thistles, for instance, if on his neighbour's fields they are allowed to seed freely. The Canadian example should serve as an object-lesson which many other countries would do well to lay to heart. W. G. F.

THE DESTRUCTION OF WASPS.

In some years it cannot be said that the wasp plague is unbearable, but there are occasions when it spreads over the country like a pestilence, and in every season there are districts where wasps are so numerous that the amount of damage they commit must run into hundreds of pounds in the course of a few weeks. Last year, for example, wasps' nests were by no means universally common, and yet in one or two parishes of southern England they were to be counted by scores. On one small estate in Sussex a gardener destroyed a hundred nests in the course of a month, while in an adjoining parish thirty nests were found in a single field! In a Hampshire parish over three hundred nests were found and taken during August and September, and these figures could doubtless have been doubled had every estate owner in the parish lent his assistance to the movement. Half-hearted measures are of little use when wasps are plentiful, for although a number of nests may be destroyed, those that are left will go on increasing in numbers and will provide enough wasps to devastate every orchard in the district. Wholesale destruction of nests is, however, by no means an impossible thing if begun in time, and the advantages of an organised campaign are undeniable. Two years ago the writer destroyed twenty-five nests in the neighbourhood of a single dwelling, with the result that hardly a wasp was to be seen after the end of August, and very little damage was done to the fruit on the estate.

The best way of dealing with wasps is to destroy as many queens as possible in the spring, but this is by no means an easy matter. Many may be caught by suspending bottles,

half-filled with beer and sugar, in sunny places on walls and in other conspicuous positions, and others may be killed by anyone who cares, armed with an old tennis racquet, to take a walk round the garden during the morning in the neighbourhood of fruit trees and flowering shrubs. On bright days during March, April, and May many queen wasps may be thus encountered and knocked down. School children, for the sake of a small reward, will always find a good many queen wasps in the spring months by looking for them in outbuildings and attics, where they are in the habit of hibernating; and even in the winter some may be discovered hiding under old sacks or anything of the kind that will give them protection from the weather. A small sum of money expended in this way is well spent, for although every queen wasp does not necessarily mean a colony, it is probable that a large percentage of them, if left untouched, live to rear a family.

The bulk of the work of wasp destruction must, however, be deferred until the workers make their appearance at any time from the middle of July onwards. The nests, which are generally, but not always, placed on the most

Various means are employed for destroying wasps' nests, but those who wish to get rid of them once for all, and with the least possible trouble, will eschew all such things as soap-suds, paraffin, squibs, boiling water, and tar. None of them is infallible, and the usual result, except in the matter of stings, is disappointing. A good plan is to take the shot out of an ordinary cartridge and fire the latter from a shot-gun, the muzzle being held close to and pointing into the mouth of the hole, so that the fumes will be forced into the nest and the occupants suffocated or temporarily stupefied. A big bucket of scalding water must be at hand, and the whole nest must be immediately dug out and placed in it bodily in order to destroy the grubs and any wasps that remain alive. This must be done after it is pitch dark, as wasps go to bed very late, and as a lantern is necessary it is not a very easy task when the hole is a difficult one to get at or the nest troublesome to dig out. A far better, and always successful, plan is to place a teaspoonful of granular cyanide of potassium (a deadly poison) down the mouth of the hole as far as one can get it, placing a sod of turf over the entrance to keep

FIG. 17.—THE ROCK-GARDEN AT KEW AS IT APPEARED ON APRIL 24. [Photograph by W. Irving.]

sunny side of a bank by the roadside or on the boundary of a field, are not difficult to find, but the search will be greatly aided by keeping a careful look-out for wasps on the wing. The observer should stand for a few minutes by a gateway or a gap in the hedge and watch for the insects as they fly backwards and forwards. If several wasps pass by in the course of a couple of minutes one may be sure that a nest is near at hand, and the nest is almost certain to be in the direction in which most wasps are flying. Those hurrying homewards also fly straighter and more rapidly than those going away from the nest. Another good place for observation is an old railing made of unstripped natural wood, such as Beech or Birch, the bark of which the wasps collect for making the "paper" of which their nests and comb are formed. Watched through a good pair of glasses this is a very interesting process, and the study of it is useful, since the wasps fly straight home directly they have collected sufficient bark to form a pellet.

in the fumes. In the morning the nest may be safely dug out (for every wasp will be dead) and the grubs in the comb destroyed. The cost of this is not more than 1½d. a nest—a cheap price to pay, surely, to be rid of several thousands of the enemy at one operation. *East Sussex.*

A SNOW-COVERED ROCKERY IN APRIL.

ALTHOUGH not so heavy as in many other parts of the country, the fall of snow experienced at Kew on April 24 last was sufficient to transform the landscape, which afterwards presented a remarkable feature at its late a period of the year. The photograph of the rock garden (reproduced at fig. 17) was taken between 8 and 9 o'clock in the morning before the snow had melted. Many bulbous plants and others were in flower at the time of the fall, but as the snow was light they were not much injured, and they completely resumed their normal appearance when the snow had disappeared. W. T.

FLOWERS OF SPENSER.

(Continued from p. 26.)

DAFFODILS.

1. She played
Amongst her watry sisters by a Pond,
Gathering sweete Daffadillyes, to have made
Gay girldons from the Sun their Torheads
fayr to shade. *F.O., III. iv. 29.*
 2. Her in daffadillyes sleeping made
From scorching heat her daintie limbes to
shade. *F.O., III. vi. 22.*
 3. With Roses dight and Goolds and Daffa-
dillyes. *Colin Clout, 359.*
 4. Upon her head a Cremosia coronet,
With Damaske Roses and Daffadillyes set.
Shepherds Calendar, April, 50.
 5. Strowe me the ground with Daffadown-
dillyes.
Shepherds Calendar, April 40.
 6. Whlome thy fresh spring flowrd, and after
hasted
Thy sommer proude with Daffadillyes dight.
Shepherds Calendar, January, 21.
- Many of the beautiful South European Daf-
fodils had been introduced into English gar-
dens before Spenser's time, but there is no
doubt that in these passages he was speak-
ing of our wild English Daffodils. See Nar-
cissus.

DAISIES.

1. The grassie Grounde with daintie Daysies
dight.
Shepherds Calendar, June, 6.
 2. Sweet Marjoram and Daysies decking
Prime.
Multipotmos, 21.
- Spenser's Daisies need no comment.

DAMSONS.

- And, if you come hether
When Damsines I gether,
I will part them all you among.
Shepherds Calendar, April, 152.

We have one native Plum in England, the
Sloe, of little value on account of its sour-
ness, but the Damson, or Damascene, Plum
was very early introduced into Southern
Europe from the East, and spread rapidly.
There is no record of its introduction into
England, but its first mention in English
literature is about 1400.

DILL.

1. Camphora, and Calamint and Dill.
F.O., III. i. 40.
2. Veyne-healing Verven, and hed-purging
Dill.
Multipotmos, xxv.

Dill is an umbelliferous, South European
plant (*Peucedanum graveolens*) of high re-
pute among the old herbalists, still largely
used in India, but very little in Europe; it
is grown for its seeds.

EBONY.

- And, for the bed of Love forlorne,
The black and doleful Ebonie.
An Elegie, 21.

Spenser could only have known the Ebony
as an imported wood. It comes from an
Eastern tree, but was used in England very
early times.

EGGLANTINE.

1. There was a pleasant arbor . . .
With wanton yvie twine entrayled atwart,
And Eglantine and Caprifole emong.
F.O., III. vi. 47.
2. In thy sweet Eglantine of Merifure.
Colin Clout, 359.
3. With Hawthorne buds and sweete Eglantine.
Shepherds Calendar, May, 15.
4. But as your worke is wovon all about
With wooblynd flowers and fragrant Eglan-
tine. *Amoretti, 71.*
5. Sweet is the Eglantine, but pricketh sore.
Amoretti, 20.

The Eglantine of Spenser and of all the
poets before and after him, except Milton in
one passage, is the Sweet Briar.

ELDER.

1. The Muses, that were wont giene bayes to
weare,
Now bringen bitter Eldre branches seare.
Shepherds Calendar, November, 140.
2. In stead of gyrlond, weare sad Cypres
nowe,
And bitter Elder, broken from the bowe.
Clorinda, 41.

To Spenser, as to most writers of his day,
the Elder was the type of bitterness and
sorrow.

ELM.

1. The vine-propp Elme. *F.O., I. i. 5.*
Though not named, the Elm is probably the
tree meant in :
2. The tree that coffins doth adore
With stately height threatening the skie.
An Elegie, 19.

The Elm with which Spenser would be
familiar was not our common Elm (*U. cam-
pestris*), which is an Italian importation and
not common till after Spenser's time, but the
Wych Elm (*U. montana*). His epithet of
"Vine-propp" is from Ovid's *Amictæ vitibus
ulmi*; it was never so used in England.

FILBERT.

- And Phyllis philbert there away
Compared with Mirtle and the Bay.
An Elegie, 17.

The writers of Spenser's day were fond of
connecting the Filbert with Phyllis. Gower
gives the reason :—

- Phyllis in the same throws
Was shape into a nutte-tre,
That alle men it might se,
And after Phyllis philliberd
This tre was cleped in the yerd.
Conf., B. IV.

But this connection was probably only an
effort to account for the word, which is an
old English word used long before Gower. In
the Latin legend Phyllis was turned into an
Almond tree; and in France the word is con-
nected with S. Philibert, whose festival falls
in the nutting season.

FIR AND FIRBLOOM.

1. Sweet is the Firbloom but her braunches
rough. *Amoretti, xxvi.*
2. The Firre that weepeth still.
F.O., I. i. 9.

I suppose that, by the weeping of the Fir,
Spenser alluded to the exuding of the pitch,
chiefly from the cones; but I cannot guess
what he meant by the Firbloom.

FLAX.

- Like snarks of fire which fall in slender
flax. *F.O., III. i. 47.*

The Flax is not a true British plant, but it
readily escapes from Flax fields, and was
known and cultivated in England long before
Spenser's time.

FLEUR DE LIS.

1. The Lily, Lady of the flowering field,
The Flowre-deluce her lovely Paramour.
F.O., II. v. 16.
2. Now of late
As fresh and fragrant as the Flowre-deluce.
F.O., IV. i. 51.
3. Adorned all with gemmes of endlesse price,
And all embost with Lyons and with Flour-
deluce. *F.O., I. ix. 27.*
4. The prettie Pawnee
And the Chevissance
Shall match with the fayre flowre Deluce.
Shepherds Calendar, April, 130.

The Fleur de Lis of all writers of the six-
teenth and seventeenth century was the Iris.

GILLIFLOWERS.

1. Bring hether the Pink and purple Cullam-
bue,
With Gilliflowres.
Shepherds Calendar, April, 130.
2. Her lips did smell lyke unto Gilliflowres.
Amoretti, 64.

Spelt in many ways, but originally con-
nected with the French Girofle, a Clove, the
name was applied to almost any Clove-
scented flower, but in Spenser's time it was
for the most part confined to the many dif-
ferent varieties of Pinks and Carnations.

GOOLDS.

- With Roses dight and Goolds and Daffa-
dillyes. *Colin Clout, 359.*

Goold is one of the old names of the Mari-
gold.

GOURD.

- Whose caerule streame, rombling in Peble
stone,
Crept under mosse as greene as any goord.
Virgils Gnat, 21.

In Spenser's time the name was applied to
almost any plant of the Cucumber tribe.

HAWTHORN.

1. Seest thou not thilke same Hawthorne
studded,
How bragly it begins to budde,
And utter his tender head?
Shepherds Calendar, March, 15.
2. To dight
All the Kirke-pillours eare day light,
With Hawthorne buds and sweete Eglan-
tine.
Shepherds Calendar, Maye, 11.

So far as I know, this is the only passage
that tells us of the decking of churches with
May flowers on May Day.

HAZEL.

- Which he so sternly shooke,
That like an hazel wand it quivered and
quooke.
F. O., II. vii. 24.
- See also Filbert.

HEBEN.

1. A gentle youth, his dearly loved Squire,
His speare of Heben wood behind him
bare. *F.O., I. vii. 37.*
2. And trees of bitter gall, and Heben sad.
F.O., II. viii. 52.
3. That stranger Knight,
Whom all men term'd Knight of the Heben
Speare. *F.O., II. v. 5.*
4. That bore the Hebene speare. *The Knight
F.O., IV. v. 20.*
5. But knowne by fame and by an Hebene
speare. *F.O., II. vi. 6.*
6. At sea a tall ship did appeare,
Made all of Heben, and white Yvorie.
Visions of Petrarch, 2.
7. Soone after this I saw on th' other side
A curious offer made of Heben wood.
Ruins of Time, 3.
8. Lay now thy deadly Heben bow apart.
Intr. F.O.

It is now generally accepted that Shake-
speare's "deadly Hebenon," with which
Hamlet's father was poisoned, was the Yew,
and I should think it almost certain that, in
all these passages, the Yew was the wood
meant and not the Ebony. Of course I re-
cognise the poet's right to equip the Elin
Knight with the costliest and most outlandish
materials, but where the more common and
every-day material will serve the purpose as
well or better, there is no reason to look
further. Certainly, in the last quotation, the
Yew is the material of the bow, and I think
that, to a great extent, explains all the
others. H. N. Flacombe.

(To be continued.)

KEW NOTES.

THE ALPINE HOUSE.

The small plant house at Kew (see fig. 18), in which the Alpines are exhibited when in flower, is one of the least pretentious, but at the same time one of the most interesting glass houses in the gardens. In late winter and through spring onwards the choicest gems of the Alpine garden may be found in flower, some in the bud and others passing out of bloom, according to their season. The house is not intended for the culture of the plants; they are removed when their flowering is over to give place to others that are about to bloom. With the glass protection the blooms are saved from damage by heavy rains, and, in consequence, they last longer in a fresh condition than flowers of similar species that develop in the open. With bulbous plant the house is kept bright and interesting from the middle of December onward to the end of May. The first to bloom are the

and Erodiums. The Kew Alpine house was built in 1887, and was enlarged in 1891. It is 40 feet long, 9 feet wide, and 8 feet 6 inches high at the apex. It is an unheated structure, and in the winter the soil in the pots is often frozen. W. L.

COLONIAL NOTE.

FRUIT CROP IN THE NIAGARA DISTRICT OF CANADA.

The fruit prospects in this and surrounding districts of St. Catharine's, Fonthill, and Welland County are excellent. If the weather continues favourable it will be the best fruit crop we have had for the past ten years. Peach, Cherry, Plum, Apple, and Pear trees are loaded with fruits. Apples Mackintosh, Red Fameuse (Snow Apple), Baldwins, Baxters, Wealthy, Twenty Ounce, Newtown Pippin, and King of Tompkins County are abundant croppers in the districts. The only market variety that is

Strawberries are also plentiful, but the price of Strawberries will be dearer this year owing to the scarcity last season. The price was fixed in the early spring this year by the canning factories, namely, \$1.50 per crate of 30 lbs. (6s. 3d.). This price has never been equalled in this part of Canada. Strawberry growers will therefore reap a benefit. Young men coming out to Canada next spring will succeed if they select this part. The residents are chiefly English and Scotch. W. H., *Fonthill Nurseries, Canada, June, 1908.*

BARBADOS.

In December, 1905, it was decided to carry out experiments with the object of improving the Cotton grown in Barbados by seed selection as outlined in the *West Indian Bulletin*, Vol. iv., p. 208, and arrangements were made for the work of selection to be carried out on seven estates. From one of these estates—Stirling—15 plants were obtained, and from these 15 three plants were finally selected, viz., Nos. 300, 301, and 303 (*West Indian Bulletin*, Vol. vi., p. 159).

FIG. 18.—THE ALPINE HOUSE AT KEW IN MAY.

[Photograph by H. Irving.]

winter-flowering Colchicums, such as *C. Decaisnei* and *C. hydrophilum*, and Crocuses of various kinds, which are in flower in December; these are followed closely by bulbous Irises, including *I. alata*, *I. steuophylla*, *I. Varianii* and numerous others. Crocuses, Scillas, Chionodoxas, Snowdrops, and Anemones are other beautiful things that carry on the succession of bloom in conjunction with such Alpine plants as *Androsaces*, *Primulas*, *Shortias* and *Saxifragas*, to the end of May.

The plants required for furnishing this Alpine house are grown in shallow pots or pans plunged to the rim in ashes in cold frames—Bulbs for the purpose are potted up in autumn and are plunged outside in ashes till they flower.

The illustration is from a photograph taken at the end of the season in May, the chief plants then in flower being late-flowering species of *Saxifraga*—*S. longifolia*, *S. Cotyledon*, &c., *Dianthus alpinus* and other species, *Cypripedium*, *Meconopsis*, *Wahlenbergias*, *Ranuncias*,

not an average crop this year is Northern Spy, but there was a good crop of it last year. Pears will be abundant, especially "Bartlett's" (Williams' Bon Chretien, Kieffer's Hybrid, and Dempsey's).

All varieties of Plums, including the Japanese varieties, viz., Abundance, Burbank, Red June, and Manyards, are very heavy croppers, and there is also a good crop of Pond's Seedling. Peach trees are a far better crop this year owing to the soft breezes that prevailed at the time they were in bloom; the pollen was nicely distributed, and there were no frost or east winds just then. I have visited most of the largest Peach growers in these districts and found very little Peach blight, and only one instance of that dread pest, the San Jose scale, and the grower was having all the trees in the orchard rooted up and burned. The remedy used in these districts is sulphur and hot lime in the winter and early spring before growth commences.

Recently Dr. C. E. Gooding, the proprietor, shipped, under the mark "Stirling S," seven bales of cotton from plants grown from the seed obtained from the plant No. 303, and Messrs. Wolstenholme and Holland, in reporting on this cotton, write:—"We have formed a very high opinion of this latter lot ('Stirling S'), as it is the most serviceable class of cotton we have seen produced in the West Indies, and if it gives a better yield per acre than the finer descriptions—as it probably will—we think it is more suitable for extensive cultivation."

This cotton, as Messrs. Wolstenholme and Holland correctly surmise, has for the last four plantings given heavier yields in the experiment fields at Stirling than any of the other varieties grown.

The opinion expressed by Messrs. Wolstenholme and Holland is very encouraging, and shows the desirability of systematically and regularly carrying out the selection of the best seed for planting purposes.

* THE FRENCH SYSTEM OF MARKET GARDENING.

The culture of Lettuces in France has become a fine art, because they are grown by market gardeners who have devoted the greatest and most careful attention possible to them, and have thus accumulated a considerable body of experience in the subject.

The method of cultivation used in France was not always so perfect as it is to-day. They obtained fewer crops per year. Lettuces were first cultivated in 1780, white Asparagus in 1792, Cauliflower in 1811, Cos Lettuce in 1812, C. cut in 1836.

There are now 3,000 acres under cultivation in the environs of Paris, held at a rental of £2 to £40 per acre.

A garden of 400 lights and 3,000 cloches costs £120 per annum for manure. The frames were originated by M. Fourmier in the year 1780, and from that time to this they have been improving their method of growing these early Lettuces.

The success of their form of cultivation depends on the beds. By constantly using manure the soil becomes very rich, as the beds are renewed at least three times a year.

The method used is shortly as follows:—They make hot-beds—not what you would call hot-beds—but what they call "soft couches," or softly-heated beds.

The manure is collected during the summer and piled in stacks. They begin to collect in June, and continue collecting until Christmas. This manure naturally gets exhausted by losing its heat during the time it is in stack, but they get fresh manure in December, and they mix half and half with the old manure which has been standing.

When a quantity of frames or cloches are used, the manure is spread evenly all over the ground 9 inches deep.

The frames are then placed on the pressed-down manure, about 12 or 18 inches being left between the rows or frames, just giving room to walk between. Three or six inches of the very best soil, preferably mixed with one-year rotten manure used for the frames during the preceding season, should be placed in each frame and well pressed down and raked. The frames are then ready to receive the Lettuces in January, and, as there is no great demand for early Lettuces during the extreme winter months, it is not worth while starting the frames earlier, since they would not pay for the extra care and attention required.

Lettuces being the principal crop, I have not yet referred to the other varieties of early vegetables that should be grown on the same bed.

The French, in their careful, methodical, and practical way, make use of every inch of room, and instead of getting one crop out of the beds they get four.

As soon as the beds are ready for the Lettuces in January, sow some Radishes thinly, at the same time sowing some of the very early Carrot (early frame), also very thinly in the same frame or frames; or, instead of Radish, sow some Half-long White Turnip.

This being done, the frame is now ready for the small robust Lettuces which have been growing on under the bell glasses, and towards the end of December they should be as large as five shilling pieces.

WINTER CABBAGE LETTUCE—EARLY FRENCH.

SOW IN OCTOBER.

This variety is small, having very small hearts. It grows very well indeed under frames or bell glasses during the winter, but it is of no use except for this purpose. One can have Lettuces all through the winter by using the following method.

At the beginning of October sow the seed under bell glasses, and as soon as the first two leaves after the cotyledons appear prick them out under other bell glasses, 20 to 25 to each glass. In November dress round with old manure from the exhausted beds. Protect the glasses well from frost and very heavy rains by covering them with litter and mats, which are taken off during the middle of the day if the

weather permits, but without giving air. This lot of plants is ready to plant out in the frames in January.

Each light should contain 21 plants, and the bed must be high enough in the frame for the plants to be not more than 4 inches from the glass.

The Radishes will come along very quickly, and should be ready for pulling in March, or in about six weeks from the time they are sown.

This will give more room for the development of the Lettuce, which will grow quickly now, and should be ready for cutting by the beginning of March.

After the Lettuces are cut and sent to market, plant out four plants of Early Frame Cauliflower in each frame.

CAULIFLOWER.

From the beginning of September until the end of the month, sow seeds of Early Frame Cauliflower in the open ground in an old hot-bed or in a piece of open ground; they will be up in eight days, and fifteen to twenty days after the coming up of the seed, transplant them into frames so that they may be covered with lights, or under cloches if these be used. Cover a piece of ground a yard wide with 1½ inch of old rotten manure from the exhausted beds. Then transplant them at the rate of twenty to twenty-five plants per bell glass, the lesser number being the better. If the season is very open and the plants grow too quickly, it is necessary to pull them up and replant them immediately in the same place. Let them have air every day when it is fine, so that they harden the plants and helps them to withstand the frost and cold. The Cauliflowers will be ready to plant out in the frames when the Lettuces have been cut in February and March.

To obtain a crop of Cauliflowers in April and May, sow from August 25 until September 5, and winter the plants preferably in frames; plant them out 3 or 4 inches apart.

About the middle of February make a bed of half exhausted manure, and half new manure 15 inches deep, ten or twelve days afterwards plant these Cauliflowers out at a distance of about 8 inches, putting a cloche over each; these are, of course, in addition to those planted under the lights. Four Cabbage Lettuces can also be planted under each cloche. Fill up between the cloches with dry litter, to the top when necessary, covering the whole with double straw mats. The Cauliflower should be ready to cut in April. After those in the frames are well established, the lights and frames can be lifted off and utilised for Cucumbers or Melons, the plants of which have been got ready in a small hot-bed.

EARLY CUCUMBERS AND MELONS.

In the early days of February sow seeds of both Melons and Cucumbers. There are several varieties of each, the Cantaloup being one of the best for frames, as it is the earliest, the fruit being very fine, of good size and superior flavour. The best variety is Little Prescot.

To raise Cucumbers and Melons now, make a small hot-bed of fresh stable manure in which to raise the plants; for transplanting into larger hot-beds next month to remain to fruit; a small bed for a one or two light frame may be sufficient, and about two or three good cart-loads of fresh hot manure will be enough for making a bed of proper dimensions for a frame of three lights.

The Carrots which have been growing in the frames must be carefully thinned to allow them to develop more quickly, and this is really one of the most profitable crops. An enormous number of these Carrots, which of late years have been fetching 6d. per bunch of twelve Carrots, can be pulled from one frame.

The particular Cabbage Lettuce that Frenchmen grow is one that has never been used in this country except in the few French gardens now existing. It is totally different to any Lettuce we are in the habit of growing here. If this Lettuce is planted in spring it will immediately run to seed.

There are 2,100,000 of these cloches used in the immediate neighbourhood of Paris, and there are 1,000,000 frames or lights.

The vegetable produce from these lights fetches the enormous sum of £500,000. Now I want to know why market gardeners, such as

yourselves, cannot grow some of this produce here?

The cry in the past has always been that our climate is not the slightest good for growing these vegetables, and that in France they have neither frost, fog, nor snow; that they have nothing to contend with, and that the Frenchman has no difficulty or trouble in rearing his plants.

Let me tell you that this is not the case. The Frenchman who I obtained for the French garden at Evesham told me that the climate there (Evesham) was greatly to be desired, and that Lettuce did not fog off there as they did in Paris.

Now in this very pleasant town of Cheltenham you are warm, and on the sandfields and Absoia Road I am sure there are ideal spots which might be used for this kind of gardening.

There is nothing to prevent each of you investing in 30 to 40 lights, which would cost you, roughly, £20, packing included, and then you would want a small quantity of cloches, anywhere between 50 and 100, which would cost, roughly, between £3 to £5 10s. per 100.

These would never be a loss to you, as if you could not use them for this kind of work, they are admirably adapted for work with some other of your crops.

(To be continued.)

The Week's Work.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., LEIT, PERTHSHIRE, N.B.

Pandanus Veitchii.—Old plants should be kept for the purpose of increasing the stock. They should be placed in a position exposed to full light, and the bottom leaves should be stripped for a considerable way up the stem, in order that the suckers also may be exposed to the light. Select the thin, small suckers from the base of the plant, in preference to the thicker and stronger ones. These suckers should be placed singly in small thumb pots filled with a compost consisting of loam and peat in equal proportions, with enough silver sand added to keep it porous. Make the soil firm about the suckers, and plunge the pots in a hot bed. Following the application of the first watering, the soil should be kept on the dry side, otherwise the suckers will be liable to decay. In re-potting *Pandanus Veitchii*, the soil should always be made very firm, and if the leaves show too much green colour, apply an artificial manure to the roots, selecting a manure that contains a good proportion of iron.

Zora.—Plants that are coming into flower must be examined in order that it may be ascertained that there is no mealy bug amongst the buds; otherwise the flowers will not open kindly. Slightly spraying with some safe insecticide will destroy the bug, and will do harm upon the flowers. Make frequent applications of liquid manure to the roots at this season. Regulate and tie the flowering shoots evenly over the plant, screening the stakes from view as much as possible.

Codiaeum (Croton).—Examine the plants of *Codiaeum* very frequently for mealy bug. Tie the shoots into the shape and form desired. Make frequent applications of manure to the roots, taking care always that the doses are not made too strong. Damp the surfaces in the house frequently, and syringe the plants at least twice each day when the weather is bright.

Palms.—Plants that have filled their pots with roots, but which it is not intended to repot into larger pots will be benefited if a thick layer of sphagnum moss be placed on the surface of the soil and frequent applications of diluted manure water are given. Barkboots, if grown in pots, are greatly helped if treated similarly.

Zonal Pelargoniums.—Plants raised from cuttings last spring should now be potted in 6-inch pots, and in these they may be allowed to flower during winter. A compost of rich loam, leaf-mould, and a little bonemeal is suitable. Pot firmly, and place the pots in a bed of ashes in a position exposed to the sun. Keep all the flowers picked off until it is desirable to allow the plants to bloom.

* Being a paper recently read at Cheltenham by Mr. C. D. Kay, of Messrs. Watkins & Simpson.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Oncidium.—The members of this extensive genus are all evergreen plants with flowers of great beauty; some are large growing and gross feeders, whilst others are small, delicate, close growing members. The majority possess pseudo-bulbs, but in one section these swollen stems are absent, their place being taken by large, showy leaves growing from a thick, hard rhizome. With plants varying so much in habit, the mode of culture naturally varies. In the case of species not possessing pseudo-bulbs, as represented by *O. luridum*, *O. Lanceanum*, *O. tetrapetalum*, *O. variegatum*, *O. carthagenense*, &c., all of which flower during the late spring and summer months, the plants should be placed in the warmest division of the house in a position where they may enjoy plenty of light, without actual sunshine. They may be grown in pots or pans on the stage. Plenty of material for drainage should be afforded, as they enjoy copious supplies of water during their growing season, and overhead syringing may be practised on bright days. The plants are best potted above the rim of the receptacle, and they must be fixed firmly in the compost. This section of *Oncidium* is not the easiest to manage during their resting season in

about the roots. This species is not one of the easiest to maintain in a healthy condition for many years. I find they succeed fairly well when hung up in a light position in the warmest house and frequently syringed during the growing season.

Oncidium papilio and *O. Kramerianum*.—These species may be bracketed together as far as their treatment is concerned. Both thrive best in a shady corner of the intermediate house, and require very little compost about their roots. Plenty of moisture at the roots is needed when the plants are making fresh growths, and the foliage should be kept well syringed on fine days. The wiry peduncles rise from the base of the pseudo-bulbs, and bear one flower at a time at intervals all through the summer and early autumn months. The frequent flowering ultimately weakens the spikes, as shown by the smaller flowers produced, and when this is observed the old inflorescences should be cut off, when fresh vigorous ones will soon form.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

The weather.—The welcome rains that have fallen recently have done much to improve the

for the purpose, and should be planted in soil that is not excessively rich, it being easy afterwards to supply the necessary stimulants. Be careful to allow plenty of room between each plant.

Vegetable Marrows.—The later plants should be afforded a liberal mulch with long stable litter. Regulate the growths, apply frequent root waterings, and syringe the foliage occasionally. Those in full bearing will need manure water, and should not be allowed to support any fruits after they are ready for cutting. Examine the plants two or three times each week.

Courds and Pumpkins.—In whatever position these are grown it is necessary they should complete their growth as soon as possible and set a good crop of fruits, in order that these latter may have sufficient time to mature perfectly. Most of the edible varieties make excellent food during the winter, but they cannot be preserved until that period unless they have first been properly ripened. As soon as sufficient fruits are swelling on a particular plant expose the fruits as much as possible, and apply manure water liberally to the roots.

Tomatos.—See that Tomatoes have a liberal mulch of long litter over their roots. Remove superfluous growths and stop the leading shoots as soon as a good crop of fruits has been

FIG. 19.—A GROUP OF RHODODENDRON "PINK PEARL" AS EXHIBITED BY MESSRS. DICKSONS AND CO., CRAIGMILLAR, AT THE RECENT SCOTTISH NATIONAL EXHIBITION, EDINBURGH.

winter, when naturally much less water at the roots suffice, but the plants must never be allowed to suffer from drought, as they have no pseudo-bulbs like their congeners to support them.

Oncidium ampliatum majus is a magnificent species, the flowers of which are produced in spring. This plant should also be accommodated in the warmest division of the plant house, as it delights in a high temperature, exposure to sunlight early in the afternoon, and a moderately moist atmosphere during its season of growth. It is best grown on rafts, or in shallow baskets suspended from the roof rafters. A thin layer of rooting material only is required, and this should be placed on a good layer of drainage materials. If the plants are treated liberally during the growing season they seldom fail to produce good pseudo-bulbs, with foliage of a thick and leathery texture.

Oncidium Jonesianum.—This is a charming autumn-flowering species, the plants having small pseudo-bulbs that are scarcely to be distinguished from the leaves, to which they form a thickened base. These succeed best when placed on rafts with the foliage hanging downwards. A little material should be packed between the bars to help conserve the moisture

general appearance of the crops, and so far as can be seen at present most of them, especially the root crops, are likely to produce a good yield.

Runner Beans.—These plants appear very promising; the pods are setting freely and the plants are vigorous. Regulate the shoots in order to get them to cover their supports regularly but thinly, cutting out such lateral growths as is necessary to prevent overcrowding, and stopping the leading shoots after they have reached the top of the stakes. Plants in full bearing may be given an abundance of water, and drainings from the farmyard if sufficiently diluted have a very beneficial effect. In wet weather one of the artificial manures especially recommended for vegetable crops may be applied in place of the liquid, but the quantity should in no case exceed that given in the directions. Gather the pods as soon as they are ready, excepting any that are required for seed purposes. When once a good strain has been obtained, take every care to maintain it, selecting the very best pods only each season for continuing the stock.

French Beans.—Make two or three sowings of these in unheated frames during the next four weeks. Canadian Wonder is a capital variety

assured. Should dull weather occur, shorten the leaves, expose the fruits as much as possible to the sun's rays, and do not overfeed the plants.

Winter Greens.—Continue to plant all kinds of Greens as the ground becomes available. If these have to be planted between the row of Potatoes the Potato haulms should be carefully laid down, which will not harm the Potato crop but allow the Greens more light.

Turnips.—Turnips have been the least satisfactory crop in this district, except such Turnips as have been cultivated in frames. Sowings should be made at intervals of ten days in shallow drills drawn at 12 inches apart on finely prepared ground. Jersey Lily and Snowball are excellent varieties for the present purpose.

Peas.—Thin out both the plants and side shoots of late plants as they require it, staking and tying in the growths. If extra good pods are needed, the plants must be grown very thinly and the pods themselves must be thinned out. To prevent attacks of mildew, apply a mulch and give an abundant watering to the roots.

Asparagus.—Support the strong growths with stakes to prevent them being blown down by winds before they have matured.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANSAGE, Lockinge Park, Berkshire.

Borders of mixed flowers.—Examine the borders frequently and remove the decayed flowers. In some instances the foliage also decays early, and in such cases suitable plants should be introduced from the reserve garden to fill the vacant places and maintain a succession of flowers.

Plants for flowering in spring.—Many of the spring flowering plants recently removed to the reserve garden will need to have their blooms removed, and either by cuttings or division of the roots some will need to be propagated for raising stock to flower next spring. A border that faces to the north is a suitable site for such propagation to be carried out, but care should be taken to see that the soil is made sufficiently sandy and that it be kept loosened at frequent intervals. We are now planting out seedling *Aubrietias* in variety, and *Wallflowers*, *Alyssum*, *Verbascum*, *Geranium*, *Arabis*, and similar plants, if divided now will make fine tufts for autumn planting. Seeds of the following species are now being sown:—*Myosotis* (*Forget-me-nots*), *Silene pendula* *compacta*, *Papaver nudicaule*, *Campanula* (*Anterbury Bell*), perennial *Lupinus* in variety, *Scutellaria*, *Heuchera sanguinea*, and others.

Carnations.—What are known as the tree or perpetual-flowering Carnations, and which are usually grown under glass for flowering during winter in pots, flower very well with us during the summer months of doors. They are planted very early in summer. Each plant is provided with stakes, and the stems are neatly tied to the stakes so that they cannot be blown about by the winds, otherwise the blooms would be worthless.

Carnation layers.—As soon as the flowers have been gathered and have faded on the Carnation plants, the work of layering should be commenced. Clear the plants of old flower-stalks and remove the weeds from the ground. Prick over the surface soil and add sufficient sand or grit to keep the soil exceedingly porous. Afterwards prepare mounds of finely-sifted soil containing a good proportion of leaf-mould and sharp sand. The mounds should be made of good size and fairly flat in shape, so that the water will not be thrown off. The shoots selected for layering should be the healthiest and strongest obtainable. At the point it is intended to make the incision remove the leaves and make a slanting cut in an upward direction to the middle of the stem and to 2 inches in length, with about 4 inches of upper growth beyond the cut to form the young plant. It is important to fix the layer firmly into the mound by means of a peg, and in such a position that the portion that will form the young plant will stand perfectly erect. Wire pegs are most serviceable, but it is necessary to use them of sufficient length that they will remain fast in the soil. When the layers have been planted, apply a good watering through a fine rose can. Spray the plants overhead every evening during the dry weather. After the lapse of six weeks the layers may be severed from the stem of the parent plant, and removed for planting into previously prepared beds.

FRUITS UNDER GLASS.

By T. COOMBE, Gardener to LORD LLANGATTECK, The Hendre, Monmouthshire.

Early vines.—In order to induce early-fruiting vines to thoroughly mature their shoots and develop prominent buds at the base of the laterals, promote a free circulation of warm air by night as well as by day, and prevent attacks from insect pests so that the leaves may remain healthy for as long a period as possible. On no account allow the roots to suffer from lack of sufficient moisture. In cases where the roots of the vine are in an unsatisfactory condition, and it is intended later to lift the roots or to replenish the borders with fresh compost, the necessary amount of turfy loam, crushed bones, mortar rubble, and wood ashes should be prepared at the present time, that it may be in a state of readiness for use when the leaves are seen to be changing their colour and therefore nearing maturity, this being the best time for carrying out the operation, because the roots will be enabled to take a hold of the fresh soil before losing their activity for the winter.

Mid-season vines.—Madresfield Court is one of the best mid-season Grapes. Its liability to crack, however, when commencing to colour necessitates special treatment. During the growing and ripening seasons of this particular Grape the roots, as in the case of other vines, must never be allowed to suffer from lack of moisture, and when the fruits commence to colour the house should be moderately well ventilated both by night and day, and the atmosphere kept fairly dry. The lateral growths of the vine should be allowed to extend to a reasonable extent. After Black Hamburgh has ripened its fruit, the berries are liable to lose colour in the presence of hot weather, and the fruit of Muscat of Alexandria is equally liable to shrivel. To guard against these defects I must repeat that the borders should be kept moist, but, in addition, the fruit may need to be screened from the sun's rays by the interposition of a fair amount of foliage. This is not intended to mean that the foliage should be allowed to become crowded. Rather than this, it will be better to supply a slight shading over the glass by the use of fish netting. Maintain the atmosphere of the house cool and apply ventilation freely.

Late vines.—The hot and dry weather has caused more than ordinary attention to be paid to late vines. Transpiration from the leaves during such weather is very great, and therefore it is the more necessary to apply water to the borders and to promote moisture in the atmosphere. Surface waterings are useless, it being necessary to apply sufficient to thoroughly wet the whole depth of the border. It is also important at this season, when the crops are developing, that the vines should be sufficiently supplied with quickly available manures. Neglect in this matter is likely to injure the crops next year just as it is certain to prejudice the crops already upon the vines. Stop the lateral growths at regular times, and sponge the leaves directly upon the first appearance of red spider, using soapy water. As soon as the fruits have become of sufficient size to be less liable to scalding, it will be safe to force the crops a little until the berries commence to colour by closing the houses in the afternoon when the atmospheric temperature is 80°, the atmosphere at the same time being well laden with moisture and charged with ammonia, promoted either by sprinkling the inside borders with guano or by replenishing the mulchings with fresh horse-droppings.

THE HARDY FRUIT GARDEN.

By F. JENNINGS, Gardener to THE DOWAGER LADY NORFOLK, WATERFRY, YORKSHIRE.

Morello Cherries.—Shoots required for fruiting next season or for furnishing or extending the trees should now be trained into their proper positions. In most private gardens Morello Cherries are cultivated as fan-shaped specimens against walls facing to the north, but they may also be grown very successfully as bushes in the open garden, and if pruned but moderately will produce good crops of fruit in average seasons. Even such trees as are growing against the walls will be benefited at this season by a good watering of liquid manure or by a light dressing of some artificial manure, in the latter case applying a good watering immediately afterwards. Do not train in the young wood very thickly. Encourage those shoots nearest the base of the tree to extend and eventually replace the oldest branches as the latter become unfruitful. Morello Cherry trees produce fruit on spurs and on the young wood. These shoots which are not required for furnishing the trees should be pinched back to three or four buds from the base, and they will form spurs. The branches plucked the trees from insect pests before the nets are fixed into position to protect the fruit from the birds.

Sweet Cherries.—Examine the trees as soon as the fruits have been gathered, and wringe them with some insecticide if black fly, red spider, or some other insect pest is discovered. In any case give the trees a good washing with water applied from the hose-pipe or garden engine.

Mulching and watering.—Peawders are referred to my remarks in the issue for July 4 on this subject. If the weather should be very dry the cultivators' best means of assisting the crops is

to apply fresh mulchings and water liberally directly afterwards. Trees that are swelling heavy crops of fruit and have their roots in light soils, also trees that were planted late in the spring, are among those which first feel the effects of long continued drought. Any kind of non-conducting material may be used in such a season as the present for retaining moisture to the soil and protecting the finest roots near the surface. Do not wringe the trees overhead on bright hot days, but rather defer the operation and apply a good syringing directly the sun has fallen below the horizon.

THE APIARY.

Honey in California.—In his report on the trade and commerce of the States of California, Nevada, and Utah, and the territory of Arizona, just issued (Annual Series, No. 3,958), Mr. Consul-General Hearn has some interesting references to the honey yield of California. It was predicted during last summer that the output of the year would be 5,000,000 lbs., but in fact it was almost double that of 1906, the total being estimated at 8,700,000 lbs. The beekeepers in the State consider 100 to 200 hives sufficient for any one farm. The honey gathering is usually from April to September, depending upon the weather and the length of the blooming period of the bee forage. The extracting season commences in May or June and is usually about six or eight weeks in duration. In a good season California produces about 4,500 tons of honey. One of this is the famous mountain sage honey, which is water-white, and is said to be the mildest flavoured honey in the world. In the northern part of California bees gather their stores from the bloom of the Carpet Grass and the Eucalyptus; in the central countries from *Alfalfa* and *Orange* blooms, white, black and purple Sage, *Roses*, *Sumac*, and wild *Buckwheat*. The last two give a poor grade of sweet, which is usually extracted to be used for winter feeding, and these later stores are left to the hives, if the blooming season comes when the combs are full.

The method of honey extracting, as described by Mr. Consul-General Hearn, is interesting. Details vary in different apiaries, but in one called the Model Apiary, the process is as follows:—With a hand-car, or small truck, the apiarist steps beside a laden hive; this hive is of two stories, sometimes three. With a thumb-staked knife he loosens one edge of the lid, and thrusts the mouth of the smoker beneath it. With quick pressure of the bellows he sends the smoke into the chamber, and the bees hurry below to avoid suffocation. He lifts the combs, and brushes away the stupefied bees. If the honey is capped over, or partially so, he puts the comb into wooden-handled baskets made for the purpose, and when he has a load the car is pushed to the extracting house, to which it runs on a miniature railway, which runs its cars through every street of the bee city.

Well-filled combs-hives weigh 8 to 12 lbs., according to thickness of the comb, and specific gravity of the honey. Inside the extracting house is a deep, tin-lined, uncapping box occupying nearly the whole side of the room, and in this box the frames are suspended until wanted. Uncapping is largely done by women. The frame, containing the comb, is balanced on one edge of the uncapping box, and a long knife dexterously slices off a thin sheet of wax, thus destroying the cell seals. As the combs are uncapped they are placed in the baskets of the extractor, which are reversible, and the honey is thrown out by centrifugal force. From the bottom of the extractor runs a 3-inch pipe on a gentle incline to a tank outside the extracting house. This tank holds several thousand pounds. Across the opening of the pipe where it leaves the extractor is fastened a section of wire netting with rather coarse meshes to keep pieces of comb or refuse from passing into it.

In the top of the receiving-tank is suspended a white flannel bag, 2 ft. x 12 ft. long, in the upper part of which is run an iron bar some 1 foot 3 inches in diameter, which first fits the opening in the tank; this further strains the honey. The honey is then drawn into drums, holding from 12 to 60 lbs. each. *Journal of the Society of Arts, June 11.*

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, and as far as possible on the back, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Illustrations. The Editor will be glad to receive and to select photographs of gardenings, suitable for reproduction, of suitable or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor any intelligence of local events likely to be of interest to our readers, or of an matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

The Art of Forcing.

Every gardener knows what an important part the art of forcing occupies in the ordinary work of the year. But in the earliest days of gardening practice people were doubtless more easily satisfied, being for the most part content to cultivate their crops during the natural growing season of the year, and store or preserve such kinds as were possible for consumption during the winter months. This has so far altered that we are in danger of despising fruits and vegetables when they are in season, reserving our appreciation only for the more or less unnatural products that are cultivated by excessively artificial means. Although it may be possible to carry this craving for the unnatural to an unjustifiable extent, and notwithstanding that, as a rule, most kinds of fruits and vegetables may be seen in best condition when they mature at their natural season, it is none the less true that our food supply is largely increased by the present-day systems of forcing, and the extra variety of vegetable food thus made available during the winter and spring months is healthful and agreeable. Increased attention has been directed to the art of forcing by recent descriptions in the Press of the French system of forcing vegetables. This system is that adopted in the environs of Paris by the market gardeners, or maraichers, as they are called in France. The methods consist of employing hotbeds formed of stable manure for generating heat, covering these hotbeds with a layer of soil for the cultivation of vegetables and salads, and protecting the crops by means of bell-shaped glasses or cloches and flat frames with movable lights, which are covered at night time by mats made of rushes. An enormous

amount of stable manure is used in these nurseries, and though the quantity that is necessary becomes rather less after a few years, it must remain a large item so long as the manure alone is depended upon to provide the requisite warmth. There is no doubt whatever that this hotbed and frame system has so far proved exceedingly productive in the Paris nurseries, and that the early produce has sold for remunerative prices in the Paris and other important markets. First-class Lettuces in December and January, Radishes, young Turnips, and Carrots all through the winter months, and Potatoes, Peas, Vegetable Marrows, Asparagus, Strawberries, and Cauliflowers long before their natural season of maturing are so much appreciated by most people that the prices obtained for them are out of all proportion to what they can command later in the season.

We have on our table three books which have just been published on the subject, a sufficient testimony to the interest this form of gardening has awakened in this country. The first is *The French Garden*, by Mr. C. D. McKay. Mr. McKay, may be remembered, was instrumental in taking to Paris a party of English market gardeners in 1905 for the express purpose of studying the hotbed and cloches system of forcing. One result of that visit was that Mr. Idiens determined to introduce the system to Evesham. He started in a small way and engaged a French maraicher to come and supervise the undertaking. Experience proved that what is possible in Paris is just as easy of achievement here, and under the management of the present owner, Mr. Harvey, the nursery commenced by Mr. Idiens has been greatly extended, there being now as many as 2,000 lights and 4,000 bell glasses in use. Mr. McKay's book is full of practical information and free from such exaggerated statements as have been recently current in regard to the profits to be derived from such cultivation.

Following the substitution in the first half of the last century of the present system of heating plant-houses with hot water for the earlier and less convenient system of flues, there has been, to some extent at any rate, a tendency to employ hotbeds less frequently. In the old days gardeners had not the conveniences of a well-equipped modern garden, and the improvised frame and hotbed were very frequently brought into use and for a great variety of purposes. In *The New Market Gardening* the author draws attention to this fact, and states that the present efforts to popularise the French system of forcing vegetables will result in the introduction of a method that was practised by Abercrombie and other noted gardeners in the eighteenth century, but it was certainly carried out on a far smaller scale than at present is the case in the Paris nurseries.

So far as commercial horticulture is concerned, there are doubtless many places near to large towns where at present the cost of providing heat by means of a hotbed of stable manure is much less than would be necessary to heat the frame with hot water, and it is well known also that the heat generated by decomposing organic sub-

The French Garden, by C. D. McKay. Published by the Daily Mail, price 6d.
The New Market Gardening, by W. Wicherley. Published by the Cable Printing and Publishing Co., London, price 6d.

stances is in a general way more suitable to plant life than that arising from heated water pipes. The manure thus employed serves a double purpose, because after the first year most of it is distributed on the soil and fresh manure obtained for forming new hotbeds. In this way the soil is enriched to a very great extent each season, and thus it has been described as "golden" soil by some writers.

Indeed, the soil becomes so charged with organic plant food, only part of which becomes utilisable in any one year, that it is said it would grow crops well enough for a considerable number of years without any further applications of manure being necessary.

But if stable manure, being plentiful now, is a cheap means of providing heat, the balance is likely to be much disturbed after the lapse of a few years; for the substitution of motor for horse-drawn vehicles is likely to continue, and in this case the supply of such manure will be seriously curtailed. In *Gold Producing Soil* the author discusses this phase of the subject, and states that in some of the Paris nurseries, where the soil has been cultivated for many years and is consequently of unusual richness, the hot water system of heating has been again adopted, use being made of what are termed "Thermosphons."

This only goes to show that no system of heating can be cheapest or best under all circumstances, but must remain dependent upon the situation of the nursery and many other conditions that may be expected to change from year to year.

The discussion which has recently arisen has been chiefly concerned with the question of employing the methods of the maraicher in the market nurseries, and in these columns we would suggest to head gardeners in private establishments that they also may find advantages to be derived from the cloches and hotbeds, especially for the purpose of cultivating winter Lettuces, Radishes, Turnips, and Endive. Several private gardeners have tried the cloches, and the winter Lettuces so raised have been greatly appreciated.

We may add that by the courtesy of Mr. McKay we are enabled to print the substance of a paper on French gardening recently delivered by him at Cheltenham. The first instalment appears in our present issue.

OUR SUPPLEMENTARY ILLUSTRATION shows a sketch by Mr. WORthington Smith of *Paeonia arborea lutea superba*, from material kindly supplied by Mr. GUMBLETON. This variety is a selected seedling by M. V. LEMOINE, of Nancy, from the original stock received by him from the Jardin des Plantes, Paris. The flower is larger than that of the type, and has also a distinct carmine base to the petals, which greatly adds to the beauty of the plant. This, however, does not develop itself in young specimens, and Mr. GUMBLETON states that he had to wait quite two years after receiving the plant before he saw the flower in its full beauty. The leaves are deeply cut, and with their fine bronze tint are very ornamental objects. The plant is perfectly hardy at Belgrave, Queenstown, Ireland, but in less favoured districts it should be given the protection of a cool greenhouse.

Gold Producing Soil, by T. Newcome. Published by F. & S. Steele & Co., Ltd., Craven House, Kingsway, London, price 1s.

NATIONAL CARNATION AND PICOTEE SOCIETY (SOUTHERN SECTION).—The annual exhibition will be held in the hall of the Royal Horticultural Society, Vincent Square, Westminster, on Wednesday, July 22. The hon. secretary and treasurer is Mr. T. E. HESWOOD, 16, Hamilton Road, Reading.

FLOWERS IN SEASON.—From Messrs. C. S. DANIELS & SON, Wymonham, Norfolk, we have received blooms of their strain of Auricula-eyed Sweet William. Some of the markings on the flowers are very fine.

CLUB OF R.H.S. GARDEN EMPLOYEES.—The first annual general meeting of this newly-formed club was held on the evening of the 8th inst., in the Chas. Dickens' room at Carr's Restaurant, Strand, W.C. The chair was occupied by Mr. F. J. CHITTENDEN, the Director of the Laboratory at Wisley Gardens, and the following persons were also present:—Messrs. E. M. BEAR, A. DU T. BOTTOMLEY, THOS. BEVAN, A. P. CALDWELL, G. S. DAMSELL, J. FRASER, T. FRAZER, W. J. JENNINGS, J. T. LEDGER, E. MILLER, N. A. PHILLIPS, G. PYMAN, W. K. REED, H. V. RICHARDSON, H. F. ROBSON, H. L. ROBSON, H. E. SEATON, G. E. SERV, H. SPOONER, R. J. WALLIS, B. WYNNE, and G. S. YEOMAN. Students, journeymen, foremen, &c., were thus represented from the time of Mr. WYNNE, who entered the gardens as a student in 1866. After supper was partaken, the rules of the club were drawn up and approved, and the officers for the ensuing twelve months elected. It was decided to publish at an early date a list of past and present members of the R.H.S. staff, and in order to make this as complete as possible, all who have any remembrances of old Chiswick men are requested to communicate with the hon. sec., Mr. R. J. WALLIS, R.H.S. Gardens, Wisley, Ripley. It was decided that the name of the association shall be the R.H.S. Gardens Club, and that a club journal shall be published annually at Michaelmas, and shall include a list of members with their addresses.

BOTANY LECTURES AT ABERDEEN.—At a special meeting of the Sub-Teaching and Staff Committee of the Aberdeen and North of Scotland College of Agriculture it was resolved that the teaching of botany and zoology given to the regular students of the college should also be extended to the members of the central classes. It was also decided that the teaching be done by the members of the staff of Aberdeen University. Dr. Bruce pointed out that there was in the employment of the college a member of the staff with all the necessary qualifications, and whose services were available for the teaching of the subjects under review. It was indicated that if the University scheme was not adopted there was a danger of the Agricultural College being compelled to leave the Aberdeen University buildings.

EXHIBITION OF HOME-BOTTLED AND PRESERVED FRUITS AND VEGETABLES.—On November 26 and 27 next the Royal Horticultural Society will hold their annual exhibition of home-bottled and preserved fruits and vegetables at the hall of the Society in Vincent Square, Westminster, and now that the fruit-preserving season is again with us, it may give added zeal to the lovers of this skilled domestic art to prepare fruits for awards at this exhibition. Dried or bottled fruits of any kind may be shown, subject to the conditions of: (a) there being no chemical preservative, or (b) artificial colouring matter used, (c) of their being tasted by the judges, and (d) provided they have been grown in the British islands. The schedule contains classes for bottled fruits, home-dried or evaporated fruits, preserved vegetables, jams, fruit jellies and cheeses, foreign jams, and mis-

cellaneous appliances, preserving bottles, &c. The exhibits will be judged by the most competent authorities, and the medals of the Society and prizes of money awarded accordingly. One class is specially attractive, and, it is believed, quite original. It invites for exhibition three bottles of British-grown fruit (of which one must be Raspberries), bottled and shown by amateurs. These will be examined by the judges and left in the care of the Society until November, 1909, and a silver cup and other awards given. A complete schedule and further information may be obtained from the secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.

CYANIDE OF POTASSIUM AND WASPS' NESTS.—On another page a contributor deals with the methods of extermination of wasps. Sometimes it happens that it is very desirable to take a nest as quickly as possible as, for instance, when one is found in a cornfield at harvest time. For this purpose, about a teaspoonful of potassium cyanide is dissolved in half a pint of warm water in a bottle. Approach the nest gently and pour about half the quantity into the hole. Probably no wasp will be able to fly out, and there need be no fear of being stung if the operation be done quietly. The home-ward-flying wasps will be killed as they enter the hole, and it often happens that the entrance becomes choked with dead insects, whilst others continually push their way in, only to suffer the same fate. After an hour or two it is generally safe to dig the nest out, but the unused surplus of the poisonous liquid should be handy in case the wasps continue to return in too great numbers. We have repeatedly adopted this practice ourselves, and can therefore vouch for its reliability, but the nest must be dug out, as the pupæ of the wasps are often not killed by the vapour. An advantage of using the cyanide in this way is that it rapidly becomes altered in the soil, and ceases to be poisonous.

NEW ENGLAND DAHLIA SOCIETY.—This active Society, recently founded at Boston, U.S.A., has decided to hold its first annual show in the Tremont Temple, Boston, on September 17, 18, and 19 next. The schedule comprises 123 classes, in many of which entrance fees are charged. Some of them have four prizes varying from £1 to 8s.; other classes, according to the requirements, have three or two, as the case may be. The headings under which the various classes are grouped are general collections of Dahlias, large vases of Dahlias, Dahlias grown in pots or tubs, Cactus, decorative, plain show, fancy show, pompon show, pompon Cactus, Peony-flowered, single Dahlias, giant single Dahlias, collarette single Dahlias, and Aemone-flowered. Special classes for non-commercial growers include 14 classes for one bloom in a vase, collections of Dahlias according to colour, Dahlias for size, long-stemmed Dahlias, seedlings, and a long list of special prizes are offered for exhibits of certain named varieties, &c. We observe among the donors of special prizes in Europe are Messrs. JAS. STREUWICK & SON, Messrs. J. BURRELL & CO., the GERMAN DAHLIA SOCIETY, M. ANDRÉ CHARRIER, and Messrs. DOBBIE & CO. The third number of Vol. II. of the *Dahlia News*, published by the Society, is just to hand, and is the only periodical publication dealing exclusively with the Dahlia.

A MANUAL OF INJURIOUS INSECTS.—Mr. WALTER E. COLLINGE, M.Sc., F.E.S., writes us as follows: The need of a concise, but authoritative work on British economic entomology, has been long felt by economic entomologists, teachers, agriculturists, foresters, horticulturists, and others. For some time past the author has had such a work in preparation, and has received valuable assistance from the leading workers both at home and abroad. In order to facilitate the work he now appeals to all in-

terested for assistance. It is proposed to issue the work in a series of parts (probably six or seven), each of from 100 to 150 pages, fully illustrated. A special feature will be made of the illustrations, of which a large series are already in active preparation. Any assistance in the form of: 1. Information *re* life-histories, or bionomics. 2. Photographs or drawings of injurious or beneficial insects (ova, larvae, pupæ or the perfect insects). 3. Photographs of plants, animals, &c., injured, or of examples of insect depredations, &c. 4. Photographs of celebrated economic entomologists, &c., will be gratefully and fully acknowledged. 5. Electros of author's illustrations of insects, &c., previously used, are greatly desired, with permission to use the same. Full acknowledgment of the lender or artist, and original source, will in all cases be made. The first part will contain a general introduction to economic entomology, and treat of the Collembola (springtails), Thysanura (bristletails), and Orthoptera (cockroaches, earwigs, grasshoppers, &c.). Communications should be addressed to WALTER E. COLLINGE, Uffington, Berkhampstead.

FRUIT TREE INSPECTION IN UTAH.—Our contemporary *Gardening* (Chicago), quoting the monthly report of a horticultural inspector made on May 11, states that in the month of April 74,246 trees were fumigated and inspected for planting, besides 200,000 which were already fumigated, inspected and stored away in the frost-proof houses or heeled in the ground for future delivery. Fifty-five boxes and bundles, containing about 15,700 trees, were imported, and 2,974 were condemned and burned for being diseased. The deputy inspectors, except one, who had nursery as well as orchard work to attend, have been on half-time this month, making a total of 87½ days' work, and have filed the following report: Orchards cleaned this spring, 539; orchards pruned, 468; orchards winter sprayed, 860; old trees cut down, 860; Pear trees cut out for blight, 3,220; young trees planted, 23,513; orchards visited, 646. In one district south-west of Jordan six large California spray pumps, costing over 800 apiece, have been bought and started to work, and many farmers intend to take hold of fruit raising in a manner calculated to produce results. Our worst plague in the other districts is the old pest-breeding orchards, good for nothing, and still not bad enough to be lawfully condemned.

MANURE SPREADERS.—The large crops that are annually taken from the land used by vegetable growers, make it necessary to fertilise the soil in a thorough manner. Many of the growers living in the vicinity of large cities haul manure from the city and spread it over their land. Until recently this work was done with a fork. The great success that general farmers have had with manure spreaders has led vegetable growers to experiment with them. They have proven a success, doing the work in a thorough and economic manner. One of the best spreaders now in use by the vegetable growers is the "Success," which is manufactured by the Paris Plough Co., of Paris, Ont. This spreader is equipped with an adjustable spring pulverising rack, which makes the manure fine or coarse, as desired. All the manure is thrown against the rack, and is thoroughly torn to shreds and pulverised. The tension spring allows sticks, stones, and other hard substance to pass through without injuring the machine in the slightest. The harpoon teeth effectually protect the ends of the beater. These teeth cut the long pieces of straw and grass and do not allow them to wind around the beater or choke it up, which would cause it to run hard, as is the case with many of the other makes of spreaders. Vegetable or fruit growers who are interested in the proper fertilising of their lands should write to this company for their free illustrated catalogue, which will describe this spreader in detail. *Canadian Horticulturist.*

BRACHYLOTTIS REPANDA.

This handsome shrub was introduced from New Zealand in 1896, and has been known at different times under the names of *Senecio Fosteri*, *S. Georgii*, and *Cineraria repanda*. It is well worth growing in the warmer portions of these islands on account of its noble foliage. A full description, from a botanical point of view, is given on p. 163 of Sir J. D. Hooker's *Flora of New Zealand*. As a foliage plant it is very ornamental. The leaves, which uncurl when they are about an inch in length, are at first of a warm ivory tint, a hue they retain until they are nearly 3 inches long, when the upper surface becomes pale green. This colour deepens with age to a dark, glossy green, handsomely clouded with purple-maroon. The ovate leaves, which sometimes attain a length of 12 inches and a breadth of 8 inches, are carried on foot-stalks from 4 inches to 6 inches in length and have deeply crenate margins with purple midribs and pale green veins. The underside of the leaves is coated with a silvery-white tomentum, which, as many of them display the reverse, forms a pleasing contrast to the prevailing dark green of the foliage. The specimen here illustrated has been in its present position for over eight years, and is 7 feet 6 inches in height and 7 feet through. For many years it never showed a sign of flowering, and much larger examples in Cornwall have not borne bloom. About three years ago, while visiting a Devon nursery, I saw a plant in a large pot that was bearing about 20 flower-spikes, and determined to see what root restriction would do for my shrub. A trench was therefore dug around it, at a distance of about 3 feet from the main stem, to a depth of 3 feet 6 inches, and this was filled with stones to the ground level. In the winter of 1906 about a dozen flower-spikes were formed, but the frost eventually killed them all. Last winter the bud-clusters were much later in forming, and were not far enough advanced to be injured by the frost at the commencement of the year, and later on developed well. The whole bush was absolutely covered with large flower-spikes, 268 having been counted, though there were probably more. The spike figured was 12 inches in height and 16 inches across at the base, and there were others even larger. Each cluster was composed of countless, minute flowers of a greenish-white tint, and the effect when the spikes were at their best was decidedly attractive. The specimen illustrated at fig 20 is by no means an unexampled specimen, as there was a plant at Ludgvan Rectory, which has since been destroyed by a gale, that must have been fully 12 feet high and as much through. There are also fine shrubs in the gardens of Lord Annesley, at Castlewellan, in the north-west of Ireland, and a large plant is growing in the temperate house at Kew. The *BrachyloTTis* stands shade well, and is an excellent subject for planting under trees in the warmer portions of the kingdom. Grown in pots of light soil it is an effective plant for the conservatory if the tips of the shoots are pinched frequently to secure a good shape, and it generally flowers well when pot-bound. In New Zealand it forms a small tree 25 feet or so in height, with a trunk 12 inches or more in diameter and a spreading top. *S. W. Fitzherbert, South Devon.*

NURSERY NOTES.**MESSRS. LAXTON BROS., BEDFORD.**

This nursery is noted for the large area devoted to Strawberry culture and for the raising of new varieties of this and other fruits. The land is especially suited to the Strawberry, but there is also much space devoted to fruit trees, Roses, and herbaceous plants. At the time of my visit, in the early part of the present month, the land was in a very dry condition, but it was sur-

prising to note the splendid condition of the crops generally. At all times much attention is given to hoeing the surface soil, and by so doing the plants and trees do not feel the effects of drought so badly as in the case of soil that is caked on the top. For many years Messrs. Laxton have been so reputed for their Strawberries that the good work done in vegetables (mostly Peas) has not attracted the attention it deserves. The late Mr. Thos. Laxton paid much attention to improving culinary Peas, and succeeded in getting a new type of Marrow Pea, with dwarfness of habit and earliness of fruiting combined. This was a great gain to growers, and Gradus, one of the best early dwarf Marrow Peas and a fine variety for forcing, was one of Mr. Laxton's raising. Since then such varieties as Thomas Laxton and the newer Laxtonian—the latter a splendid variety, as early as Wm. Hurst, with the size of Alderman and of the same good

the harrows to be used between the rows, and being grown in a strong, loamy soil the plants are remarkably sturdy and healthy. The importance of new stock in an old cropped garden should not be overlooked, as plants grown continuously in the same soil become weakened in constitution. For many years I had the care of a garden with a poor, thin soil resting on gravel, and the stock plants were almost worthless at the end of three years, but by having new stock every three years and growing a large number of plants as yearlings I was enabled to produce fine fruit. The best of the new seedlings of this year have been named Pineapple (see fig. 22), Epicure, and Connoisseur, and in testing their merits we had British Queen as the standard. I was much impressed with these, as they are selected for their flavour, size being a secondary consideration. The one named Pineapple has a distinct Pine flavour; it is not so sweet as some

FIG. 20.—BRACHYLOTTIS REPANDA FLOWERING AT KINGSWEAR, DEVON.

quality—have been raised at Bedford. At the present time considerable space is devoted to seedling Peas, some of which are most promising. At the end of the rows the older types are grown in limited number, but all under the same culture and sown on the same date. Great importance is paid to the habit of growth of the plant, the colour of the Peas and the free cropping qualities of the plants. Deep-green Peas find more favour than white ones, and a free-branching, sturdy haulm that bears a continuous crop with pods mostly in pairs is desirable.

Some 20 acres of land are devoted to Strawberry culture, no fewer than eight being planted for trial seedlings. Considerable space is devoted to the production of yearling plants for runners, no less than 20 acres being planted annually for this purpose. The plants are allowed ample space, which enables

kinds, and on this account will be preferred by some persons; it is of the Queen type and a mid-season variety. The fruits are medium in size, conical in shape, and of a bright scarlet colour; the flesh is firm. Of the three, I preferred Epicure, which is a delicious fruit, having a true Queen flavour and with the productiveness of Fillbasket. The parents were British Queen and Fillbasket. It is a fine grower; the fruits are medium in size, bluntly conical in shape, and they colour well even to the points. Connoisseur is the result of crossing Fillbasket with Scarlet Queen, and is the earliest of the three. The colour of the berry is a bright vermilion-scarlet, in which respect it much resembles Scarlet Queen, having also a bright pink-coloured flesh, which is very pleasant to the palate. The plant is a free grower and setter, so that it should prove valuable

for forcing. Laxton's Profit is the result of crossing that old favourite, Sir J. Paxton, with Countess. It should prove a fine market Strawberry for mid-season supplies to follow Royal Sovereign. It is a firm, large fruit of a deep red tint throughout; the berries vary in shape, but they are mostly wedge-shaped. Messrs. Laxton consider this the best of the new maincrop varieties they have raised.

Amongst varieties already in commerce the Cropper stands out prominently and is described as an improved Fillbasket. It is a very fine fruit, and a great cropper as its name suggests. It was sent out in 1907, and Messrs. Laxton report that this season it has been very fine. Rehaine was sent out in the same year. This

grounds. There are some most interesting crosses with varieties of the perpetual fruiting type. One which has been proved is the Laxton Perpetual. This should be classed as an improved St. Joseph, and is a true perpetual blooming and fruiting Strawberry; it bears from June to November good-sized fruits, having deeply tinted red flesh. The plant has a dwarf, compact habit. Other crosses of these varieties seen will be of great value, as they will prolong the season when Strawberries are available.

Among other new fruits is one of the Loganberry type, called the Laxton Berry. This is the result of crossing the Loganberry with the Superlative Raspberry, and the result is a large berry with the Raspberry flavour. The

a special feature. The Superlative Raspberry is grown in large quantities, and there were large numbers of Pear, Plum, Peach, Nectarine, Cherry, and Apple trees in various forms, the bush trees being very fine. Large quantities of herbaceous plants are grown, and much land is devoted to Roses. *G. Wythes.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE CORNELIAN CHERRY (CORNUS MAS).—In many old-fashioned gardens good examples of this beautiful flowering tree may be met with, but since the well-merited popularity of the Asiatic Witch Hazels (*Hamamelis*), this *Cornus* is not so frequently planted as in former years. The *Cornus* flowers as a rule towards the latter part of February and early in March, by which time the Witch Hazels are generally past their best. Though it attains the dimensions of a small tree, and is quite tree-like in habit, the Cornelian Cherry flowers freely when not more than 6 feet in height. The flowers, borne in small clusters on the still leafless branches, are yellow, a tint largely represented among the limited number of shrubs that flower during the winter and early spring months. When at its best this *Cornus* is so freely laden with blossoms that in the sunshine the whole specimen glows with a golden hue. It belongs to the same section of *Cornus* as the Flowering Dogwood (*C. florida*), but the bracts of the involucre, which surround the flowers, are small and insignificant, whereas in the case of *C. florida* they are large, petal-like, and white in colour. *Cornus mas* possesses a deep-coloured bark which serves to intensify the yellow of the flowers, and against a dark evergreen background, such as the Holly, the plant in flower appears to advantage. The popular name of Cornelian Cherry is derived from the colour of its fruits, and though they are freely borne in some parts of this country, in many places the fruits are seldom seen. Plants may be purchased cheaply from the nurserymen, and thrive in any ordinary garden soil. After having reached a height of from 8 to 10 feet, the plant is of slow growth, for which reason it is adapted for small gardens. *Cornus mas* is a native of a considerable portion of central and southern Europe, and was introduced to Britain more than three centuries ago. There are several varieties, some of them remarkable for the colour of the fruits, but the most popular is that known as *C. m. var. aurea-elegantissima*, in which the leaves are heavily margined with gold, and in summer flushed with red. H.

MAGGOTS IN CHERRIES.—The following extract from the *Times* speaks for itself. I met with the same thing in bought Cherries on June 15, 1907. In both cases (from the fact that English Cherries would not then be in the market) they would be imported fruit. I am not aware that such maggots have been found in English Cherries, but there is obviously a serious probability of their introduction. In Gistel's *Historien der europ. Insectenwelt*, 1856, the larva of *Trypanea cerasi* (Lin.), Schrk., is said to inhabit the flesh of Cherries. "Mr. P. Ramsey-Kent, writing under date June 29 from 38, Northcote Avenue, The Mall, Ealing, W., says:—'My wife and daughters bought to-day 2 lbs. of the best white Cherries, which were externally perfect in appearance. By chance a Cherry was opened, and their surprise was great to find a white maggot inside. Others were consequently opened, and each one with the same result. Eventually dozens were cut open, and each contained a maggot. Before being opened many were examined under a magnifying glass to see if there was any indication of a maggot having entered from the outside, but there was no such indication. When no maggot was seen at first, the fruit was squeezed, and one oozed from the body of the Cherry. Perhaps in the interests of your readers you may be glad to publish the information. It seems to me that the facts cannot be too generally known.' As the Cherries were perfect in appearance, perhaps some of your scientific readers may afford an explanation. A. O. IV

FIG. 21.—FLOWERING SPRAY OF BRACHYGLOTTIS REPANDA.

is quite different to the others noted, having many points in common with the Vicomtesse Héricart de Thury. Progress is an offspring of Latest of All and British Queen. It is very free in growing and is a late fruiting kind. Bedford Champion is an earlier seedling (1905), but of great merit. The berries are remarkable for their great size and peculiar but pleasant musky flavour. Reward, which was sent out in 1904, is a great favourite with me: it resulted from crossing Royal Sovereign with British Queen. It is a grand maincrop variety, producing huge wedge-shaped fruits. Laxton's Latest, one of the most popular of new Strawberries, was noticeable in the trial

fruits of this new berry more resemble the Raspberry and easily part from the fruit stalk. Its season is the same and the new plant grows as freely as the Loganberry. A new Red Currant variety was noticed. This is named Laxton's Perfection. It was grown by the side of Fay's Prolific, but it was double the size, both in bunch and berry, than the older kind, and the robust growth was very marked. The berries of the ripe fruits are as large as those of Comet.

In the fruit quarters I noted some splendid breadths of the Loganberry, there being upwards of 12,000 plants. I also noticed very large quantities of trained fruit trees of all kinds, cordons of Gooseberry and Currant being

FLOWERS OF SPENSER.—In Canon Ellacombe's notes on the *Flowers of Spenser* (p. 26), he remarks that the Columbine "has the peculiarity of bearing the names of two very different birds, the eagle in Aquilegia and the dove in Columbine." The English name, Columbine, of course, refers to the remarkable resemblance of this flower to a group of doves, but it is one of the mistaken etymologies, so common in plant names, to derive aquilegia from aquila, an eagle. It leaves too large a part of the word, viz., the letters egia, unaccounted for, as there is no instance in Latin of their occurrence as a mere termination. It is certain that legia is a second root-component of the word, which is derived from aqua-lego, and means "water-gatherer." Anyone who will go into his garden and look at his Columbine plants after rain or a heavy dew will see how apt the epithet is. The form and disposition of the leaves, more than in any other of our common plants, retain the water in a multitude of shining globules, so that the Columbine, independently of its flowers, is a remarkably beautiful object at such times. My late friend, Mr. C. Wolley-Dod, who had a European reputation in knowledge of the history of plant names, proved conclusively that this is the true derivation. G. H. Engleheart.

OVERHEARD IN A LAW COURT.—It was an arbitration case, in which a nursery collection of plants was the bone of contention. Counsel was anxious to make it quite clear what the various plants were. There was mention of *Gypsophila* and *Physalis*. "They are herbaceous perennials, sir," said the expert. "Herbaceous perennials are plants with annual tops and everlasting bottoms" was then offered as a definition, and, as far as it went, it wasn't bad. Daisies, Pansies, and Sweet Williams were called annuals. Rhododendrons were hit off all right as shrubs, but there was some trouble in placing Roses. Then came Strawberries, and the whole court stuck. But our expert was ready. "Strawberries are trees because they bear fruit," says he. Clearly it wouldn't have done to call them annuals, and their "everlasting tops" kept them out of perennials; they wouldn't go with Rhododendrons and Roses, nor would the witness have them included with vegetables. And so they were written down trees, although the terms of the lease forbade the planting of fruit trees. I wonder what Strawberries really are? *By.*

COLOUR MUTATIONS IN LEPTOSPERMUM SCOPARIUM.—In the issue of the *Gardeners' Chronicle* for June 20 last, Captain Dorrien-Smith gave an interesting account of the independent discovery of two coloured varieties of *Leptospermum scoparium* in the South Island of New Zealand. As the occurrence of these wild mutations is, in the light of De Vries' work, of considerable importance, I would like to put on record another instance of the same large and sudden variation. In the year 1886, in company with Mr. Walter Ainsley, of Auckland, I discovered a single plant of the rose-coloured variety of *L. scoparium* in the North Island. Varieties having some pink in the flowers are, as Captain Dorrien-Smith notes, common enough, but the single plant I saw was quite distinct from these, all the flowers being uniformly coloured a deep, bright rose—from the description given, probably similar to *L. Chapmanii* (which I have not seen), or, perhaps, rather more deeply coloured. I do not remember any difference in the colouring of the leaves. The plant was some years old, about 6 feet high, and, as far as I recollect, of the same habit as the others. It was evidently a true mutation, for all the surrounding bushes were the usual white-flowering typical variety. The contrast was so striking that it made a very strong impression on me, and I can recall the time and the place very clearly. It was about five miles north of Waiverua, on the second promontory north of the Puhou River (which promontory is, I think, the southern point of the entrance to the Mahurangi Gulf). Intending to set up a triangulation station on the ridge, I crossed the mouth of the Atemauri Creek at low tide, and struck up through the scrub a little higher up, where the slope was more practicable. Near to the top, perhaps about three-quarters of the way up, we came upon this single plant of the rose-coloured variety of *L. scoparium*.

As the situation is not very suitable for cultivation, the plant is very likely there still, and if any of your New Zealand readers were interested they might find it without difficulty, as Waiverua is only two hours by boat from Auckland. Another question of scientific interest which naturally arises is the frequent occurrence of these wild sports or mutations. A surveyor has exceptional opportunities of seeing the wild flowers of a country. Wherever possible, comparatively elevated stations are chosen for observation, and standing behind the instrument while the lines are being cut or chained, one generally has some leisure to look around over the surrounding scrub, and though one would not see every plant in the area surveyed where the boundary lines were far apart, such a marked variety as *L. Chapmanii* would at once arrest one's attention, even at a considerable distance. Taking into account how widely spread *L. scoparium* is (it is the "Tea-tree" of the colonists), and allowing that only one-third of the area traversed in surveying was more or less covered with it, I have made a calculation. I think it is a reasonable, if not a low, estimate to say that in the course of the six years I was in New Zealand I must have had under my observation three hundred million plants of *L. scoparium* in flower, and only came across one conspicuous mutation. A. J. Bliss.

SOCIETIES.

ROYAL HORTICULTURAL (HOLLAND HOUSE SHOW).

(Concluded from page 37.)

HORTICULTURAL SUNDRIES.

Messrs. THOS. GREEN & SON, LTD., Leeds and London, showed examples of their newest horse-drawn lawn mowers, and others electrically propelled; also garden rollers, lawn tennis ground marker, wheel-barrows, &c.

Messrs. HEADLEY & EDWARDS, LTD., Cambridge, showed tents, garden seats with awnings, garden arches and chairs in iron and wood.

Messrs. W. DUNCAN, TUCKER & SONS, LTD., Horticultural Builders, Tottenham, London, N., exhibited examples of small greenhouses, a tool shed, garden frames and seats, and plant tubs. In addition to these minor affairs, this firm had erected a conservatory nine paces long by about half that width. It was a good specimen of a glasshouse in which the best results could be obtained with plants.

Messrs. C. & W. BISHWELL, Victoria Works, Torquay, showed their patent collapsible square tents requiring no guy ropes; hammocks, &c.

Summer houses in peeled woods were shown by Messrs. ISMANS & CO., Royal Rustic Works, Stretford, Manchester. These were decorated with roughly-carved chunks of hard wood and varnished.

Mr. G. W. RILEY, Herne Hill, showed a pretty garden shelter, approached by two steps, thatched with thatch, and lined with match-boarding; besides showing various other

models of summer houses, he had garden seats, rustic arbours, &c.

Mr. ALEX. HAMILTON, 11, Conduit Street, London, W., showed ornamental tubs for plants.

Messrs. T. SYRER & CO., 45, Wilson Street, London, E.C., showed step-ladders, deck chairs, hand lawn mowers, &c.

Messrs. SHANKS & CO., LTD., Abroath, N.B., were the exhibitors of lawn mowers, hand, pony and electrically propelled, all of which exhibited the perfection of manufacture.

Messrs. W. WALTERS & CO., 16, Water Lane, Great Tower Street, London, E.C., showed samples of pillars of open work, arches and screens in open woodwork, and comfortable garden seats.

Messrs. SCOTT & SONS, Woodside, London, S.E., were the exhibitors of summer houses in deal and peeled oak, garden seats and plant tubs, tables, wheel-barrows and trucks. They exhibited their paraffin oil and other insecticides, garden nets, tongs, weed-killer, and a number of other sundries.

THE THAMES BANK IRON CO., London, S.E., showed three types of boilers for heating glass-houses.

THE POTTERS' ARTS GUILD, Compton, Guildford (Mrs. G. F. Watts' Village Industries), showed garden pottery, vases, seats, also sundial pedestals in red and in grey terracotta.

Messrs. C. TOFFE & SON, Stepney Square, Stepney, showed a model of a greenhouse fitted with their patent fog-purifying, self-ventilating system.

Messrs. D. DOWEL & SON, Hammesmith, exhibited garden pottery of all sorts, and numerous articles required by the gardener and exhibitor.

Messrs. H. PATTISON & CO., 4, Greyhound Lane, Statham, S.W., were exhibitors of pony and horse boots, and a steel turf renovator.

Mr. J. PINCHES, 3, Crown Buildings, Crown Street, Camberwell, showed metal plant labels, shades for flowers in shape like pierrots' hats.

Messrs. W. WOOD & SON, LTD., Wood Green, London, exhibited flower and fruit packing boxes in wood and cardboard; wood wool in various colours, hampers, wooden tongs, and sundries in infinite variety.

Messrs. W. HERBERT & CO., 7, Hop Exchange Warehouse, Southwark Street, London, S.E., showed the "Little Gripper" garden tool, for weeding without stooping; Bamboo as flower sticks and stakes, and a great assortment of sundries and stales.

Messrs. FENTON & SON, Tudor Street, London, E.C., showed the "Triad" hot-water circulating boiler in cast-iron and galvanized iron plate.

Messrs. RANSOME, SIMS & JEFFERIES, LTD., Orwell Works, Ipswich, showed horse-driven and manual lawn mowers.

Devices for exhibiting blooms of Sweet Peas and other plants were shown by Mr. J. WILLIAMS, 4, Oxford Road, Ealing, London, W.

Bottled and tinned fruits were shown from the Cape Colony by Messrs. R. JACKSON & CO., 172, Piccadilly, many of them being as yet novelties in this country.

Mr. J. GEORGE, H., Redgrave Road, Putney, exhibited fumigators, Mushroom spawn, vine manure, pot clips, Orchid peat, &c.

Messrs. WESTMACOTTIE, 150, Leadenhall Street, London, E.C., showed wines, tobacco, tinned fruits, and liqueurs from the Cape Colony.

Miss MARTIN, Auburn, New York, U.S.A., showed methods of fruit preserving in bottles with glass caps, &c.

Messrs. W. VOSS & CO., LTD., Millwall, London, showed nitro-bacarine for inoculating leguminous crops, a number of insecticides, manures for fruit-growers, &c.

Messrs. DE LUZY FRERES, Camberwell, showed a variety of sprayers, a novelty in this line being the so-called bottle sprayers; there were likewise the National sprayer of the knapsack kind, glass bottle sprayers, bellows sprayers, &c.

Messrs. WAKELEY BROS. & CO., LTD., Honduras Wharf, Bankside, London, S.E., exhibited their Hop manure, also specimens of Peach trees carrying many good fruits, which had been grown by the aid of their Hop manure, and lent for exhibition by Messrs. T. RIVERS & SON. The basis of the manure is Hops, prepared by special process.

OHLENDORFF'S, 15, Leadenhall Street, London, E.C., showed manures for the farmer and gardener.

Messrs. PULHAM & SON, Broxbourne, Herts., and 71, Newman Street, London, W., showed a number of vases, figures, sundials, terronnals, plant tubs, &c. in a durable sort of cement.

Messrs. LIBERTY & CO., Regent Street, London, exhibited a large design constructed in their garden pottery; the vases, ornamental tubs, pots, &c., being filled with various plants.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JUNE 25.—Committee present: Messrs. Ashworth, Thorp, Cypher, Ball, Ashton, Shill, Ward, Upjohn, Keeling, Stevens, Warburton, Cowan, Holmes, Parker, and Weathers (hon. sec.).

H. J. BROMFLOW, Esq., Rainhill (gr. Mr. Morgan), exhibited a choice variety of *Laelio-*

white form, and *Cypripedium Godetroyae* exquisitum.

MAX ISAAC, Esq., Blundellsands (gr. Mr. Driver), exhibited a small collection of *Cypripediums*.

E. ROGERSON, Esq., Didsbury (gr. Mr. Price), was awarded a First-Class Certificate for *Cypripedium Godetroyae* var. *Rogersonii*, a distinct and beautiful variety.

CHARLES PARKER, Esq., Preston, staged a small group of Orchids, for which a Bronze Medal was awarded. Two plants in this group were given Awards of Merit, viz., *Cattleya Mendelii* "Payne's var." and a hybrid *Odontoglossum* (unnamed).

Dr. HODGKINSON, Wilmslow (gr. Mr. Woore), was given Awards of Merit for *Odontoglossum crispum* var. *Woorei*, *Cypripedium Godetroyae* var. *Noel xanthochilum*, and *C. Godetroyae* var. *Noel*.

Mr. J. ROBSON, Altrincham, exhibited *Odontoglossum crispum* var. *liacina*.

NEWCASTLE-ON-TYNE HORTICULTURAL.

JULY 1, 2, & 3.—The summer show of this Society was held in connection with the Royal Agricultural Society's exhibition on the Town Moor, Newcastle-on-Tyne, in glorious summer weather. Trade groups were extensively exhibited, and these rendered the show one of the most attractive that the Society has ever held, but the competitive classes, with the exception of one or two instances, were very poorly contested. The local and amateur classes were practically deleted from the schedule, and this was cause for complaint by those who have so loyally supported the Society both as members and as exhibitors for many years.

The Royal Horticultural Society sent a deputation, and conferred several medals on exhibitors.

In the competitive class for a group of miscellaneous foliage or flowering plants occupying a space of 300 square feet, Mr. JOSEPH SHARP,

FIG. 23.—A PORTION OF MR. AMOS PERRY'S EXHIBIT OF ROCK-GARDEN AND WATER PLANTS EXHIBITED AT HOLLAND HOUSE SHOW. (See p. 34 ante.)

Cattleya × *Phoebe* labelled "Rann Lea var.," to which was voted an Award of Merit.

W. THOMPSON, Esq., Stone (gr. Mr. Stevens), exhibited a few interesting plants, the best of which was *Masdevallia Harryana* var. *albens*. This plant, which is new to northern Orchidists, has all the characteristics of the type, but is in colour a pale shade of chrome, and the varietal name "albens" is somewhat a misnomer. The plant received an Award of Merit.

J. McCARTNEY, Esq., Bolton (gr. Mr. Holmes), received an Award of Merit for *Cattleya Mossiae* var. *Mrs. J. McCartney*, an albino form of considerable merit. *Cattleya Mossiae* var. *Amoldiana* was shown from the same collection.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), gained Awards of Merit for *Cattleya* × *Pittiana* var. *magnifica*, *C. x mollis*, *Odontoglossum crispum* var. "Lady White," a fine

Mr. J. BIRCHENALL, Alderley Edge, gained an Award of Merit for *Cattleya Mendelii* var. *Rosita*, a very pretty pale coloured form.

Messrs. CHARLESWORTH & CO., Heaton, Bradford, exhibited a charming set of plants, principally hybrids. (Silver Medal.)

A. WARBURTON, Esq., Haslingden (gr. Mr. Dalgleish), in competition gained a Silver-Gilt Medal for a general display of Orchids. He was granted a Silver Medal for *Odontoglossum* and a Silver Medal for *Cattleyas* and *Laelias*.

J. McCARTNEY, Esq., obtained a Silver Medal for a group of Orchids.

Messrs. A. J. KEELING & SONS obtained a Bronze Medal for an interesting exhibit, in which several good *Masdevallias* were noted.

Messrs. HUGH LOW & CO., Farnfield, also exhibited Orchids in variety. *P. W.*

Huddersfield, won the 1st prize. Finely-flowered *Roses* and well-coloured *Codiaeums* (floribundus) were the principal features of this effectively-arranged group. The R.H.S. Gold Medal was awarded to this group. 2nd, A. E. BAMBRIDGE, Esq., Lynwood, Jesmond (gr. Mr. T. Bell), with a beautifully-arranged group, in which Orchids were a prominent feature. The prize included the Silver-Gilt Flora Medal of the R.H.S. 3rd, Messrs. ORR BROS., North Shields.

The best collection of Orchids in 11 cm was shown by Mr. H. A. ISSIS, Croft Road, Yorkshire; 2nd, Mr. W. LAWRENSON, Newcastle and Yarm, with a group consisting principally of *Odontoglossum*.

A class for a competitive exhibit of Carnations brought keen competition. Mr. C. E. WATERS, Balcombe, Sussex, was 1st, with a

comprehensive and finely-arranged group of good quality flowers. 2nd, Mr. W. LAWRENSON.

Messrs. BLACKMORE & LANGDON, Bath, won the 1st prize for tuberous Begonias, Messrs. ORD BROS. being placed 2nd.

The class for a collection of cut Roses was contested by one exhibitor only, Mr. F. M. BRADLEY, Peterborough, and he was awarded the 1st prize, also the R.H.S. Gold Medal.

Mr. R. BOLTON, Warton, Carnforth, had the best collection of Sweet Peas, with a magnificent display. 2nd, Mr. C. W. BRADMORE, Winchester; 3rd, Messrs. G. & A. CLARK, Dover.

For the best collection of herbaceous and hardy perennials, Messrs. HARKNESS & SONS, Bedale, was 1st, with an attractive and well-arranged group of cut flowers; 2nd, Messrs. GIBSON & Co., Bedale.

In the class for a collection of hardy foliage plants, Mr. W. LAWRENSON won the 1st prize.

The best dining table arranged with flowers and fruit was shown by Mr. J. Tulleit (gr. to Lord BARNARD, Raby Castle). In the class for a rock-garden furnished with Alpine plants and a water-garden, Messrs. J. BACKHOUSE & SONS, York, were 1st with a very effective display that created much attraction. The background was of ornamental trees and shrubs. In front were dwarf flowering plants. The Alpines being effectively disposed, the R.H.S. Gold Medal was awarded in addition to the 1st prize.

FRUIT AND VEGETABLES.

For a collection of six dishes of fruits, Mr. J. C. McPherson (gr. to Lord LONDSEBOROUGH, Market Weighton) was placed 1st. He showed good bunches of Black Hamburg and Muscat of Alexandria Grapes, Hale's Early Peach, Queen Pine, Lord Napier Nectarines, and Strawberry Royal sovereign. The collection was of excellent quality. The R.H.S. Silver-Gilt Knightian Medal was awarded it. 2nd, Mr. J. TELLETT.

Special prizes were offered for a collection of six distinct kinds of vegetables. Mr. T. H. BOLTON, Powderham Castle, Devon, was given the 1st prize, Mr. J. HENDERSON, Christon Bank, the 2nd, and Mr. E. KEITH, Wallington, Cambo, the 3rd.

NON-COMPETITIVE EXHIBITS.

Messrs. R. SMITH & Co., Worcester, were awarded the R.H.S. Gold Medal for a remarkable group of well-grown, beautifully-coloured, ornamental hardy trees and shrubs, staged in the open. Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, staged a group of Orchids, Carnations, and a miscellaneous collection of flowering and foliage plants. Messrs. W. CURRISH & SON, Highgate, N., showed a fine group of Carnations, Queen Alexandra, Verbenas, and dwarf Begonias. Messrs. C. & A. CLARK, LTD., Dover, had a display of Sweet Peas and cut spikes of Delphiniums. Messrs. R. H. BATH, LTD., Wisbech, sent miscellaneous garden flowers. Messrs. W. H. HARDY, LTD., Gosforth, had an extensive group of tree Carnations and miscellaneous flowering and foliage plants. Messrs. LITTLE & BALLANTYNE, Carlisle, had a fine collection of stove and greenhouse flowering and foliage plants, also in open well-grown ornamental trees and shrubs in pots. Mr. A. EDWARDS, Arnold, Notts, showed rustic arrangements with Sweet Peas. Messrs. DOBBIE & Co., Rothsay, had their usual tastefully-arranged stand of Violets, Pansies, and fine bunches of Sweet Peas. Messrs. JARMAN & Co., Chard, showed Roses. Messrs. LAING & MATHER, Kelso, had a display of well-grown ornamental trees and shrubs in pots. Messrs. DIXON'S, Chester, sent a large exhibit of cut hardy flowers. Messrs. BACKHOUSE & SON, York, had a large group of Carnations and stove and greenhouse plants. Mr. F. EDMONDSON, Newcastle, showed floral devices. Messrs. ORD BROS. staged a group of stove and greenhouse ferns. Mr. W. LAWRENSON had a large group of stove ferns and foliage plants. Messrs. W. & J. BROWN, Peterborough, exhibited Roses, also greenhouse and hardy flowering plants. Messrs. KENT & BRYDON, Darlington, arranged in the open clipped plants in tubs and hardy ornamental trees and shrubs. Messrs. LANTON BROS., Bedford, had a very fine display of Strawberries in variety, for which the R.H.S. Silver-Gilt Knightian Medal was awarded.

In the agricultural section, Messrs. R. SMITH & Co., LTD., had an exhibit of culinary Peas and miscellaneous vegetables. Messrs. MACK

& MILN, Darlington, displayed foliage and flowering plants in variety, including Roses. Messrs. KENT & BRYDON, Darlington, had a fine display of well-grown vegetables, a fine group of "Malmaison" Carnations, Liliums in variety, and numerous stove and greenhouse plants. Messrs. DICKSON'S, Chester, showed Carnations, Spiraea "Queen Alexandra," and foliage plants. Messrs. WEBB & SONS, Stourbridge, showed fruit and vegetables, a fine collection of Gloxinias, Sweet Peas, and greenhouse flowering plants. Messrs. J. CARTER & Co., London, displayed vegetables, retarded Liliums, Gloxinias, greenhouse flowering plants, &c. Messrs. SUTTON & SONS, Reading, had a noteworthy exhibit of annuals, Gloxinias, Scanzhanus, Liliums, Sweet Peas, &c. Messrs. DIXON, BROWN & TATE, Manchester, showed dwarf Roses, Spiraea, and Lily of the Valley. Messrs. LITTLE & BALLANTYNE, Carlisle, showed miscellaneous stove and greenhouse plants and a collection of Sweet Peas. Messrs. DICKSON & ROBINSON, Manchester, staged Sweet Peas, Irises, and Carnations. Messrs. W. FELL & Co., Hexham, showed hardy flowers, pot Roses, and Gloxinias. Messrs. FENNEY showed Sweet Peas, Carnations, and Lily of the Valley.

SCOTTISH HORTICULTURAL.

JULY 7.—The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh, on this date. Mr. Whytock, the president, occupied the chair, and there was a good attendance of the members. Mr. Daniel Kidd, gardener to Lord Elphinstone, Carberry Tower, Musselburgh, read a paper on the "Strawberry." Mr. Kidd dealt with the propagation and cultivation of the plant. The lecturer stated that for forcing, where a large, good flavoured early fruit was required, he did not know of a better variety than Royal Sovereign. It is open he preferred to make plantations at the end of the summer rather than in spring, and if the runners were pegged down into square pieces of turf inserted between the rows they could be planted out in August. When the ground was not ready for planting in summer it was a good plan to lift the runners when well rooted and plant them at from 4 to 6 inches apart each way in 4-foot beds, and transfer them to their permanent quarters about the middle of March. He condemned digging between the rows with the spade, but advocated mulching the plants as soon as they have made new leaves, instead of deterring the operation until they are in flower. The three best varieties for furnishing fruit for preserving are Black Prince, Grove End Scarlet, and Vicomtesse H. de Thury. Mr. Kidd, in conclusion, made a brief reference to the Alpine varieties, which he said might be termed perpetual fruiterers, for fruit could be had from the parent plant in July, and a succession from the young growths in October. They grow well in a light soil, but require an ample supply of manure. The paper for the next monthly meeting on August 4 will be by Mr. C. Comfort, Bloomfield, on "Modern Garden Appliances." Two new members were elected.

SOUTHEND-ON-SEA HORTICULTURAL.

JULY 7, 8.—This Society held its annual summer exhibition of Roses, Sweet Peas, fruit, vegetables, &c., on these dates in the spacious rooms and winter garden of the Palace Hotel. The show as regards quality of exhibits and number of entries was a decided improvement upon last year's exhibition. Roses were an especial feature, Messrs. B. R. CANT & SONS, FRANK CANT & Co., and D. PRIOR & SON all contributing excellent displays of these flowers. In the six classes open to nurserymen and others for Roses, the firms indicated secured all the prizes, staging magnificent blooms of leading varieties.

In the class for 48 blooms of distinct varieties Messrs. FRANK CANT & Co. won the Challenge Cup presented by Captain J. R. B. Newman, D.L., J.P., together with a money prize, the most prominent blooms in their exhibit being Her Majesty (satiny rose-pink), Rosomane, Mme. Gravereaux, Countess of Oxford, Horace Vernet, White Maman Cochet (very fine), Dean Hole (grand), Mme. Constance Souper, Lady Ashdown, William Shean, Bessie Brown, Boadicea (pinkly-white), Duchess of Portland

(cream), Maman Cochet (very fine), Hugh Dickson, Mildred Grant, Papa Lambert (pink), and Xavier Ocho. 2nd, Messrs. B. R. CANT & SONS, whose best blooms included White Maman Cochet, Florence Pemberton, William Shean, Mildred Grant, Fran Karl Druschki, and Earl of Dufferin. Messrs. D. PRIOR & SON were a good 3rd. In the class for 18 Tea or Noisette blooms of distinct varieties the winners were as follows: 1st, Messrs. B. R. CANT & SONS; 2nd, Messrs. FRANK CANT & Co.; 3rd, Messrs. D. PRIOR & SON, all staging fine blooms, the most noteworthy in the 1st prize stand being White Maman Cochet, Mme. Constance Souper, Bridesmaid, Souvenir de Pierre Notting, Ernest Metz, Ethel Brownlow, and The Bride.

Twelve distinct varieties, three blooms of each.

—Messrs. B. R. CANT & SONS won the 1st prize, staging fine blooms of Her Majesty, Bessie Brown, Gustave Piganeau, Maman Cochet, A. K. Williams, Hugh Dickson, White Maman Cochet, and Mrs. Theodore Roosevelt. Messrs. F. CANT & Co. being a good 2nd, and Messrs. D. PRIOR & SON a close 3rd. In the class for one dozen blooms of one variety of a H.P. Rose, the exhibitors named occupied the same positions as in the two previous classes, the 1st and 2nd prize stands containing respectively fine blooms of Frau Karl Druschki and Her Majesty.

The same exhibitors as in the three previous classes occupied similar positions in the class for 12 blooms of one variety H.T., Mildred Grant and Dean Hole being staged in fine form by each grower.

Messrs. FRANK CANT & Co. were the only exhibitors of 12 bunches of garden Roses, and won the 1st prize.

AMATEUR CLASSES (OPEN).

Mr. W. LEGGETT, Colchester, was the 1st prize winner in the class for 24 distinct varieties, staging among other varieties grand blooms of Dean Hole, Horace Vernet, Kaiserin Augusta Victoria, Florence Pemberton, Bessie Brown, and David Harum.

Mr. ROBINS, Ingatstone, was 1st for 18 distinct varieties. 2nd, Mrs. BARNES, Rochford.

In the class for six varieties, three blooms of each, Mr. W. LEGGETT won the 1st prize; 2nd, Mr. ROBINS—both showing good blooms. In the class for 12 Teas or Noisettes, distinct varieties, Mr. LEGGETT was again successful with good all-round blooms, the Rev. F. R. BURNSIDE, Great Stambidge Rectory, Rochford, being 2nd.

Messrs. LEGGETT and BURNSIDE again occupied the same positions in the class provided for eight Tea or Noisette Roses of distinct varieties, three blooms of each. Local amateur rosarians also showed good blooms in the several classes allotted to them.

Three silver medals of the National Rose Society were offered for the best blooms in the show of Hybrid Perpetual Rose, Hybrid Tea, and Hybrid Tea or Noisette varieties respectively. Mr. W. LEGGETT secured two of the medals with large, well-formed fresh blooms of Horace Vernet and Dean Hole, the Rev. F. R. BURNSIDE being awarded the other for a fine flower of White Maman Cochet.

In the Ladies' classes several dinner table floral arrangements, epergnes, &c., were effectively arranged by Mrs. TALBOT, Mrs. BLAKELEY, Mrs. H. E. CAMPBELL, Miss H. G. CAMPBELL, and Miss F. E. CAMPBELL. Mr. W. A. VOSS, Rayleigh, was the most successful amateur exhibitor.

Messrs. SALTMARSH & SONS, Chelmsford, were successful in the classes for Sweet Pea.

Vegetables and fruit were fairly well shown in the numerous classes provided for them.

WOLVERHAMPTON FLORAL FETE.

JULY 7, 8, 9.—The twentieth annual floral fete was held in the spacious, well-kept West Park, Wolverhampton, on these dates. As usual, the large plant groups were a feature: Roses and Sweet Peas were also shown in good condition. Fruit trees in pots from Messrs. T. RIVERS & SON, Sawbridgeworth, and gathered fruit from Mr. J. Doe (gr. to Lord SAVILE, Rufford Abbey), displayed great cultural skill. Vegetables of excellent quality were shown in quantity.

PLANTS (OPEN).

The two principal group classes were for (1) plants in and out of flower, and (2) foliage plants only, each to be arranged on a space of 300 square feet. Prizes amounting to £57 10s. were offered in each class, and three exhibits were staged in each of them, being the same number as in 1907. The leading prize in the first-named class was won by Messrs. JAMES CYEPHER & SONS, Queen's Road, Cheltenham, whose plants showed excellent culture and were artistically arranged. The group was almost identical with the one which won premier position for the same firm last year. The 2nd award was gained by Mr. W. HOLMES, West End Nurseries, Chesterfield; the 3rd by Mr. W. VAUSE, Leamington.

The 1st prize in the class of corresponding importance to the above-named, but confined to foliage plants, was won by Mr. W. HOLMES, with a pleasing arrangement of well-cultured *Codiaeum*, *Caladiums*, *Aceris*, *Pandanus Veitchii*, *Alpinia Sanderi*, *Begonias*, &c. 2nd, Mr. W. VAUSE; 3rd, Mr. G. HANCOX, West Bromwich.

Six Exotic Ferns.—1st, Mr. W. MANNING, Dudley, with handsome specimens of *Davallia filifera robusta*, *Gleichenia Mendelii*, *Microlepia hirta cristata*, *Adiantum formosum*, *Nephrolepis davallioides furcans* and *Cyathea medullaris*. 2nd, J. A. KENRICK, Esq., Berron Court, Edgbaston (gr. Mr. A. Cryer).

In a class for twenty plants (at least eight to be in bloom) growing in pots and not exceeding 8 inches in diameter, three exhibits were forthcoming, the 1st prize being won by Messrs. JAS. CYEPHER & SONS, for large handsome specimens of *Ixora Pilgrimii* and *Williamsii*, *Clerodendron Balthouii*, *Bougainvillea Sanderi*, *Chromola xifera*, *Anthurium Scherzerianum*, *Acalypha Sanderi* and *Codiaeum*. 2nd, Mr. H. BLAKEWAY, Rugby; 3rd, Mr. W. VAUSE.

In another class similar to the last-named, but restricted to twelve plants, of which six were to be in bloom, Messrs. JAS. CYEPHER & SONS again carried off the 1st prize. They had profusely-flowered specimens of *Erica Cavendishiana*, *Bougainvillea Cypheri*, *Ixora Williamsii*, *Allamanda Hendersonii*, and *Phorocoma prolifera Barnesii*. 2nd, Mr. W. VAUSE.

A class was provided for a collection of flowering plants limited to one kind, but any number of varieties of the same kind were allowed. The group was restricted to a ground space of 9 feet by 5 feet. Here again Messrs. JAS. CYEPHER & SONS beat all comers with a splendid collection of bushy, profusely-flowered *Ericas*. 2nd, J. A. KENRICK, Esq., Edgbaston (gr. Mr. A. Cryer), who depended upon *Begonia Gloire de Lorraine* and its variety *Turnford Hall*. The plants were profusely flowered. 3rd, Mr. JOHN E. KNIGHT, Wolverhampton, with *Zonal Pelargonium Beauty*.

Tuberous-rooting Begonias.—Mr. F. DAVIS, Pershore, the only exhibitor was awarded the 1st prize for a collection of unnamed double-flowered varieties. The flowers were large and shapely and of good colours.

PLANTS (AMATEURS).

J. A. KENRICK, Esq., Edgbaston (gr. Mr. A. Cryer), won the 1st prize for a collection of plants. The group was arranged with great taste.

Mr. H. BLAKEWAY, Rugby, showed the best six stove and greenhouse plants, and C. MARSTON, Esq., Compton (gr. Mr. W. E. Wall), won the 1st prize for 12 *Gloxinias*, his plants having rich and delicately-coloured flowers of great substance.

ROSE CLASSES (OPEN).

Roses were extensively and well shown. The champion class was for 72 blooms of distinct varieties, for which a sum of £42 was offered in three prizes. The winners of the 1st prize of £20 were Messrs. D. PRIOR & SON, Colchester, with flowers of excellent quality. A few of the best examples were *Innocent Birkla*, *Mildred Grant*, *J. B. Clark*, *Duke of Wellington*, *Mrs. E. Mawley*, *Dean Hole*, *Comte Rainbad*, *A. K. Williams*, *Gustave Piganon*, *Hugh Dickson*, *Liberty*, *Princess Marie Mercketsky*, *Charles Lefebvre*, *Suzanne Marie Rodocanachi*, *Killarney* and *Bridesmaid*. 2nd, Messrs. R. HARKNESS & Co., Hitchin, who had shapely flowers of *Dean Hole*, *Horace Vernet*, *Her Majesty*, *Ben Cant*,

and *Papa Lambert*. 3rd, Mr. HUGH DICKSON, Belfast.

Forty-eight blooms of distinct varieties.—Five competitors staged in this class. Messrs. D. PRIOR & SON were awarded the 1st prize with exquisite flowers of *J. B. Clark*, *Comte Rainbad*, *Caroline Testout*, *Duke of Wellington*, *Mamie Cochet*, *Souvenir d'Elise Vardon*, *Miss Marje Correll*, *Mildred Grant*, *Dupty Jamin* and *Muriel* *Grahame*. 2nd, Messrs. R. HARKNESS & Co., who had *Mildred Grant*, *Fran Karl Druschki*, *White Maman Cochet*, *Duchess of Bedford*, *Madame Haassmann*, and *A. K. Williams*.

Twelve distinct varieties, three blooms of each.—The 1st prize in this class also went to Messrs. D. PRIOR & SON, who staged superb blooms of *Madame Cochet*, *Bessie Brown*, *Horace Vernet*, and *Mildred Grant*. 2nd, Messrs. J. TOWNSEND & SONS, Worcester. 3rd, Messrs. R. HARKNESS & Co.

Twenty-four blooms of distinct varieties.—The best of five exhibits came from Messrs. D. PRIOR & SON, who had splendid specimens of *A. K. Williams*, *Princess Marie Mercketsky*, *Hugh Dickson*, *Horace Vernet*, *J. B. Clark*, and *Captain Hayward*. 2nd, Messrs. R. HARKNESS & Co., whose best blooms were *Lady Moyra Beaucher*, *J. B. Clark*, *Ben Cant*, and *Marie Baumann*.

In a class for 12 varieties put into commerce during the years 1906-7, for which a Gold Medal and £2 were offered as the 1st prize, Mr. HUGH DICKSON was placed 1st. The varieties shown were beautifully fresh and shapely, and were as follows:—*Yvonne Vacherot*, *Mildie*, *Simone Beaume*, *J. B. Clark*, *Mrs. Peter Blair*, *Lyon*, *William Shean*, *Mrs. John Bateman*, *Milly Crean*, *Queen of Spain*, *Madame Leon Pain*, *Mrs. Stewart Clark*, and *M. de Luze*. 2nd, Messrs. D. PRIOR & SON, whose best flowers were *Queen of Spain*, *Mrs. John Bateman*, *William Shean*, and *Countess of Gosford*.

The last-named exhibitors had the best twelve dark coloured Roses in the variety *Victor Hugo*. Mr. HUGH DICKSON was 2nd with *J. B. Clark*. In the next class for twelve light coloured Roses, *Mildred Grant* was well shown by the last-named exhibitor.

Twelve Tea Roses, distinct.—The best exhibit in this class was staged by Messrs. D. PRIOR & SON, who had exquisite blooms of *Souvenir d'un Ami*, *Muriel Grahame*, *Madame Jules Graverene*, *Souvenir d'Elise Vardon*, and *Mrs. Edward Mawley*. 2nd, Messrs. J. TOWNSEND & SONS.

Only two exhibits were made in a class provided for twelve bunches of decorative Roses to be shown as grown, each bunch to contain three stems. 1st, Mr. JOHN MATCOCK, Oxford, whose flowers of *Madame Abel Chatenay*, *Liberty*, *Gustave Regis*, and *Rosa Mundi* were much admired.

Messrs. PERKINS & SONS, Coventry, had the best bowl of Roses, Mr. J. BARROW being 2nd. In the next class for a vase of Roses the awards were reversed.

Bouquets and cut flowers (open).—Competition in the classes provided for these was stronger than was the case last year. Messrs. PERKINS & SONS, Coventry, carried off 1st prizes in each of the following classes:—(1) Bouquet for the hand; (2) bridal bouquet (with Orchids) and bridesmaids' bouquets (Orchids excluded); and (3) feather-weight bouquet. Mr. W. J. GARNER, Hull, was awarded 2nd prize in each class.

The first position for a collection of hardy flowers, arranged on a table space of 15 feet by 5 feet was gained by Messrs. G. GIBSON & Co., Seeming Bar, Bedale, and Messrs. W. FEMBERTON & SON, Bloxwich, Walsall, took the 1st prize for a very dainty arrangement of Pansies and Violas.

There were four decorated dinner tables: that arranged by Mr. W. J. GARNER was placed 1st. The effect of this table would have been improved by the use of fewer flowers.

In another class for dinner-table decorations, confined to amateurs, several very neat and pretty displays were to be seen. The 1st prize was awarded to Mrs. MARBLE, Penkridge, whose table was ornamented with rink Sweet Peas and sprays of *Selaginella* and *Gypsophila*.

SWEET PEAS.

Sweet Peas were shown in great quantity and in good condition. For a collection of 18 varie-

ties, for which the sum of £7 10s. was offered in four prizes, Sir R. S. BAKER, Bart., Blandford (gr. Mr. A. E. Usher), was awarded the premier place among five competitors. The blooms were large, substantial, and such varieties as *Elise Heibert*, *Andrey Crier*, *Mrs. H. Sykes*, *Mrs. Breadmore*, *John Ingham*, and *Helen Lewis* were well shown. 2nd, Mr. T. JONES, Raubon.

The prizes offered by Mr. Henry Eckford, Wem, for 12 varieties brought two exhibits. 1st, Mr. T. JONES, with handsome flowers, beautifully arranged.

Mr. Robert Sydenham also offered prizes in a class for Sweet Peas. Here there were six contestants for a handsome silver bowl offered as 1st prize and £2 10s. as second prize for 18 varieties. 1st, Mr. T. JONES, Raubon, with uncommonly good flowers of *Primrose Spencer*, *Henry Eckford*, *Helen Pierce*, *Black Knight*, *George Herbert*, *Frank Dolby*, and *Countess Spencer*. 2nd, Sir R. S. BAKER, Bart., Blandford (gr. Mr. A. E. Usher).

The last-named exhibitor beat eight competitors in Messrs. Baker's class for Sweet Peas with a splendid collection nicely arranged.

Messrs. Sutton & Sons offered a guinea as 1st prize for the best bunch of the variety *Sutton's Queen*. Five exhibits were staged, the 1st prize being won by Mr. T. JONES.

FRUIT AND VEGETABLES.

Fruit and vegetables were well shown. In the leading class for gathered fruit, eight dishes were required, these to include two varieties of Grapes (one black and one white, three bunches of each) and one Melon (Pineapples were excluded). The 1st prize was won by Lord SAVILE, Rufford Abbey (gr. Mr. J. Doe), with *Madresfield Court* and *Muscad of Alexandria* Grapes, *Dryden* and *Pineapple Nectarines*, *Brown Turkey Fig*, a seedling Melon, and two dishes of Peaches. The 2nd award went to the Earl of HARRINGTON, Elvaston Castle, Derby (gr. Mr. J. H. Goodacre), whose fruits, except *Muscad of Alexandria* Grape, were good. 3rd, Hon. E. F. S. WOOD, Temple Newsam (gr. Mr. R. Dawes).

Lord SAVILE (gr. Mr. J. Doe) won 1st prizes in the classes provided for (1) four bunches of Grapes (two black and two white), (2) two bunches of white Grapes, and (3) two bunches of black Grapes. H. J. KING, Esq., Ashford, Kent (gr. Mr. G. Weston), was 2nd in the first two classes, and Lord HARLEIGH, Oswestry (gr. Mr. T. Lambert), 2nd in the last-named class.

Lord SAVILE (gr. Mr. J. Doe) staged the best three dishes of Strawberries.

The Earl of HARRINGTON (gr. Mr. J. H. Goodacre) sent the best green-fleshed Melon, the variety being *Royal Favourite*, and the best scarlet-fleshed Melon (*Read's Seedling*).

Lord BAGOT (gr. Mr. T. Bannerman) won the 1st prize for Peaches with excellent fruits of *Royal George*. The Hon. E. F. S. WOOD, Temple Newsam (gr. Mr. R. Dawes) was 2nd with *Abeel*, and Messrs. T. RIVERS & SON, Sawbridgeworth, 3rd with *Persephone*.

Of the single-dish classes, the one provided for Nectarines found most favour with exhibitors. The dish of Pineapples which gained the 1st prize for the Earl of LATHOM, Ormskirk (gr. Mr. B. Ashton), was the handsomest dish of Nectarines in the show. 2nd, Lord SAVILE (gr. Mr. J. Doe) with *Dryden*. The last-named exhibitor staged the best three dishes of Tomatos.

FRUIT TREES IN POTS.

Notwithstanding the very handsome prizes offered in the above class, Messrs. T. RIVERS & SON, Sawbridgeworth, were the sole exhibitors. They were, however, deservedly awarded the 1st prize for a splendid collection, which contained examples of *May Duke* and *Knight's Early Black Cherries*, *Crimson Galande* and *Thomas Rivers Peaches*, *Cardinal* and *Victorine Nectarines*, *Apples*, *Plums*, *Oranges*, and *Lemons*, &c.

SPECIAL PRIZES.

Messrs. Sutton & Sons offered prizes for six distinct kinds of vegetables. The 1st prize was won by the Duke of PORTLAND, Welbeck Abbey (gr. Mr. J. Gibson). 2nd, the Marquis of NORTHAMPTON, Northampton (gr. Mr. A. R. Searle).

The premier prize in Messrs. Webb & Sons' class was won by the last-named exhibitor.

The Rt. Hon. Lord HATHERTON, Penkridge (gr. Mr. H. Taylor), secured the 1st prize, also offered by Messrs. Webb & Sons, for six kinds of vegetables, open only to amateurs and gardeners residing within 10 miles of Wolverhampton.

First-class Certificates were awarded to each of the undermentioned plants: Sweet Pea A. B. Bantock, from Messrs. BAKER'S, Wolverhampton; Viola Master Joseph Chamberlain, from Messrs. BASTOCK & SONS, Moseley; Delphinium Guy Dickson, from Messrs. DICKSON'S, Chester; Delphinium Gloriosa and Gaillardia The King, from Messrs. HARKNESS & SON, Bedale.

HONORARY EXHIBITS.

MESSRS. CLIBRAN'S, Hale, Manchester, contributed a collection of small, well-coloured Codonans, mostly narrow-leaved varieties. Light well-grown Caladiums occupied the centre of the group. (Silver Medal.)

MR. ROBERT SYDENHAM, Tenby Street, Birmingham, had a table of Sweet Peas artistically arranged in rustic stands. (Silver Medal.)

MR. THOMAS DARLINGTON, Walton, Carforth, exhibited 50 varieties of Sweet Peas of much merit (Silver Medal.)

MR. JOSEPH LAMBERT, Southport, displayed Sweet Peas, Carnations, and Roses in rustic stands.

M. J. KING, Esq., Ashford, Kent (gr. Mr. J. G. Weston), had an effective arrangement of "Malmaison" and perpetual-flowering Carnations.

FROM MR. F. LILLEY, Gurnesey, came a group of Gladioli and miscellaneous hardy flowers. (Silver Medal.)

MESSRS. WEBB & SONS, Stonebridge, occupied a large space with a collection of fruits and vegetables, together with indoor plants and miscellaneous flowers. (Silver Cup.)

MR. JOHN E. KNIGHT, Wolverhampton, staged floral designs, also flowering and foliage plants in variety. (Silver-Gilt Medal.)

MESSRS. JARMAN & CO., Chaid, showed Sweet Peas, Zonal Pelargoniums, and Roses. (Silver Medal.)

MESSRS. SETTON & SONS, Reading, had a long table, on which Melons, Tomatoes, Cucumbers, celeriac and Sweet Peas, and a lovely batch of Nemesis showing great variety of colour were effectively displayed. (Gold Medal.)

MR. H. N. ELLISON, West Bromwich, staged an interesting collection of Ferns. (Silver Medal.)

MESSRS. DICKSON'S, Chester, exhibited a large collection of herbaceous flowers & 1st Roses in a beautifully fresh condition. (Gold Medal.)

The most extensive, and certainly the most beautiful, non-competitive exhibit came from Messrs. BAKER'S, of Codrall and Wolverhampton, whose group of outdoor flowers arranged on the ground had an irregular frontage and was divided into several sections. In the centre there was a well-constructed rockery, on which Campanulas, Saxifragas, Dianthus, Acantho-limon glumaceum, dainty Ferns, and a host of other choice subjects were planted in positions such as the real plant enthusiast loves to see. At the base of the rockery, flowers of Nymphæas and similar plants were floating on water, on either side of which border and edge garden plants were exhibited in great variety. On a table near by representative collections of Sweet Peas and Roses were shown in splendid condition. (Silver Cup and Gold Medal.)

MESSRS. F. & H. SUCKLING, Wolverhampton, had an arrangement of floral devices, together with cut flowers of Sweet Peas, Carnations, Delphiniums, &c. (Silver-Gilt Medal.)

MISS S. S. THOMPSON, Alford Road, Handsworth, showed cut flowers, plants, including several of uncommon species. (Silver Medal.)

MESSRS. CURTISH & SON, Highgate, staged a handsome collection of hardy flowers, including Romneya Coulteri, Eremurus, Sheldford, Daringtonias, Sarracénias and choice Nymphæas. (Gold Medal.)

FROM MR. C. F. WATERS, Balcombe, came one of his characteristic displays of Carnations, representing "Malmaison," Perpetual Flowering and border varieties. (Gold Medal.)

MR. ROBERT BERTON, Canford, sent a delightful collection of Sweet Peas. (Gold Medal.)

THE BAHSIS AND PARKS COMMITTEE OF THE WOLVERHAMPTON CORPORATION (SUPT. MR. A.

WEBSTER) showed three groups of miscellaneous flowering and foliage plants. (Silver-Gilt Medal.)

MR. W. LOWE, Beeston, Notts, staged Roses and herbaceous flowers. (Gold Medal.)

FROM THE NURSERY OF MESSRS. T. RIVERS & SON, Saubajeworth, came a collection of fruit trees in pots similar to those already referred to in one of the competitive classes. (Gold Medal.)

MESSRS. BOYES & CO., Leicester, showed Carnations and Roses. (Silver Medal.)

MESSRS. T. B. DOBBS & CO., Wolverhampton, had a model garden on the lawn, in which flowering plants were arranged in groups. Rustic arches and poles were clothed with climbing Roses; Ferns, &c., formed an edging to the various borders. (Gold Medal.)

CROYDON HORTICULTURAL.

JULY 8.—On this date the above Society held its 11st annual exhibition, and was unfortunately in the matter of weather, as has frequently happened in the case of this annual show. The show was not open in the meadow in which the show was held, and the rain made matters very unpleasant for the visitors. The exhibits were accommodated in several large marquees, and quite filled them; indeed, for some things the space was much too limited.

Croydon Show has long been famed for its Roses, especially in the open classes, but this year there was a noticeable falling off in the numbers of these flowers owing to seven other flower-shows occurring in the district, the great heat of the sun in the previous week also had the effect of bringing on the blooms quickly.

OPEN ROSE CLASSES.

The blooms shown in this section were equal in all points to those we noticed at the National Society's exhibition at Regent's Park Botanic Gardens, and they kept in a fresher condition, the weather being cooler, and the air laden with moisture.

The first prize for 48 distinct varieties of Roses, with which goes the National Rose Society's Silver-Gilt Medal, was awarded to Messrs. FRANK CANT & CO., Braiswick Nursery, Colchester, for blooms of large or small size according to the want of the variety. There were extremely fine blooms of Mildred Grant, Maman Cochet, Duke of Teck, G. Laing, Paul in large-petalled blue-lil variety, Florence Pemberton, Papa Lambert, W. Shead, Victor Hugo, Horace Vermet, J. B. Clark, Duke of Connaught, François, Michelon, Souvenir d'Elise Yarden, Franz Kiet Druschki, Madame Constant support. Therefore the contribution, as it will be noted, consisted of varieties new and old, forming a splendid mass of blooms. The 2nd prize fell to Messrs. B. CANT & SONS, of Colchester, the exhibit being strong in the Hybrid Tea varieties, as will be apparent in those of our selection, viz., Dean Hole, Comtesse de Nadailac, The Bride, Mildred Grant, Maman-Dr W. Gordon, G. Hill, and Robert Scott. The blooms of crimson-coloured H.P.'s, viz., "Chas. Lefebvre, Marie Baumann, Prince Arthur, and A. C. Williams were very beautiful.

Twenty-four Roses, distinct, in triplets.—In this class Messrs. FRANK CANT & CO. were again placed 1st with many of the same varieties that were found in the larger competition. Other than those, we remarked blooms of Lady Fitzwilliam, Mrs. J. Laing, Princess M. Meyhertsky, Captain Hayward, and the fine Irish Rose Ulster. The 2nd prize was awarded to Messrs. B. R. CANT & SONS for blooms but very slightly inferior to the winning exhibit. We noted that remarkably striking variety, Commandant Feltre, five triplets of Hugh Brunner, His Majesty, and Alfred Colomb.

In a class for 24 Roses of distinct varieties, in which those who show in the first two classes cannot compete, Mr. E. J. HICKS, Rose grower, Twyford, Berks, won the 1st prize with blooms showing evenness in regard to size and good quality, and nearly identical in names with those in the other 24 Roses class.

For eighteen blooms, 2/3 or Noisette, distinct varieties.—1st, Messrs. B. R. CANT & SONS, and E. CANT & CO., 2nd. These exhibitors had evidently devoted their fine flowers to the larger competitions. In their contributions to this class there were noted fine examples of Jean Dupuy, Emilie Conin, Madame Cusin, Madame

de Watteville (a variety not often shown), Golden Gate, Mrs. Morley, and Muriel Graham.

Twelve Roses of one variety.—1st, Messrs. B. R. CANT with Dean Hole, a variety we have never observed shown better in shape, size and colour; the same variety won the 2nd prize from Messrs. B. CANT & CO., but the colour in this case was fainter. 3rd, Mr. E. J. HICKS, with blooms of that distinguished Rose Florence Pemberton.

The best twelve blooms of a Tea or Noisette Rose.—were shown by Messrs. F. CANT & CO. in White Maman Cochet; 2nd, Messrs. B. R. CANT with the same variety.

AMATEUR CLASSES (OPEN).

For the best forty-six Roses, distinct.—The 1st prize and Challenge Cup went to E. B. LINDSELL, Esq., Hitchin, Herts. His outstanding blooms were C. Lefebvre, A. K. Williams, Duchess of Bedford, Dean Hole, Lady M. Beauclore, Cleopatra, Bridesmaid, and Her Majesty; 2nd, A. TATE, Esq., Downside, Leatherhead, who had fine blooms of Oberholzgartner Tercks, Gustave Pignoneau, Marchal Niel, Beauty of Waltham, and Horace Vermet; 3rd, E. J. HOLLAND, Esq., Sutton, Surrey.

Twenty-four Roses, distinct varieties.—1st, E. M. EVERSFIELD, Deane Park, Horsham, who had notable blooms of Hugh Dickson, Mrs. E. Mawley, Maman Cochet, White Maman Cochet, and Florence Pemberton; 2nd, E. J. HOLLAND, Esq., with fine examples of Bessie Brown, Comte Raimbault, W. Shean, and Françoise Michelon.

Six Roses distinct, shown in triplets.—1st, E. J. HOLLAND, Esq., with fine examples of Dean Hole, Mildred Grant, Her Majesty, and White Maman Cochet; 2nd, E. M. EVERSFIELD, Esq., in whose box were very fine blooms of Bessie Brown and Florence Pemberton.

The best 12 blooms of one variety were shown by E. M. EVERSFIELD, Esq., who had fine examples of white Maman Cochet; 2nd, E. J. HOLLAND, Esq.; and 3rd, F. SLAUGHTER, each with the same variety. There were many other smaller competitions in the Open Classes.

There were several local Rose classes open to amateur residents in the borough within three miles of the Town Hall. One of the principal prizes is a Challenge Cup, subscribed for in 1908, which goes with the 1st prize in the class for 12 Roses distinct. It was won by H. G. MORTON, Esq., Brantwood, Purley, with blooms of average merit; 2nd, D. R. HARVEST, Esq., Camden Road, 28, Croydon; 2nd, G. H. ASHBERY, Esq., Wallington. There were competitions for six H.P.'s, six Teas or Noisettes distinct, and six Roses of one variety. In this last class Mr. P. H. BECK, Onslow Gardens, Wallington, showed Florence Pemberton excellently, one of the blooms being accounted the finest in the show.

MISCELLANEOUS EXHIBITS.

Coleus, as small plants, took up much space, but there was nothing seen in them that indicated superior cultivation. Ferns were shown in considerable number, and some good specimens were noted.

Caladiums were shown, but they were small-sized plants. Fuchsias showed a great improvement on last year's show, being better bloomed and trained and more symmetrical. The best Fuchsias were in pyramidal form and about 6 feet high. They were shown by C. CHAPMAN, Esq., Thornton Heath.

Specimen plants in flower were few. The best was a Bougainvillea glabra shown by Mr. I. AINE (gr.). A himenocera were noted, formed into pyramids 1 feet high, planted in cylinders of wire-work filled with moss and soil.

Tuberous-rooted Begonias gave patches of bright colour in the tests, likewise Pelargoniums of the Zonal section. Mr. BUTCHER, Nurseries, South Norwood, contributed many plants of a decorative nature.

Mixed flower and foliage groups were well placed with a background of large Palms, and there were several which showed a knowledge of plant arrangement, and made pleasing groups. Sweet Peas were extensively shown.

There was but little fruit shown, beyond a couple of dishes of Strawberries and a few bunches of good black and white Grapes; many specimens of Cucumbers were noted.

REMARKS.—There is a fair trade for best samples of Kent and Lincoln new Potatoes. Consignments from Jersey have finished. *E. J. Newborn, July 15, 1918.*

COVENT GARDEN FLOWER MARKET.

Supply and demand are now equally uncertain. Some growers still have bedding plants, and one informed that he is just doing a better trade in small bedding plants than with Ferns and other large decorative plants. At the end of the season buyers are slow to purchase anything except what they have on order.

Flowering plants are well supplied. *Lilium longiflorum* in pots are over plentiful, and this morning (Wednesday) many were left unsold at closing time. *Campanula isophylla* alba and the blue variety "Maya" are seen. *Crassulas* are not quite so plentiful. *White Marguerites* are abundantly supplied. *Kambler Roses* are still coming from several nurseries, but extra large plants are not procurable. *Spirea japonica* is good and there are plants of the pink varieties, but these are very expensive. *Ericas* are now heavily finished for the season. *Pteris* includes *Zonitis*, *luteo-veined*, and show varieties, all being very good.

In foliage plants, Ferns in all sizes are well supplied nothing new is seen in these plants. *Asplenium nidus* still remains a favourite, and *A. bifidum* sells well. *Aralia Sieboldii* in short, sturdy plants is seen. *Falms* have not a great demand. *Asparagus tenuissimus* is seen in good plants, also *A. Sprengeri* and *A. plumosus*.

CUT FLOWERS.

Sweet Peas are seen in large quantities; I noted this morning that many were left over at closing time. *Roses* are uncertain, there are large quantities of second quality cut from the open ground, but best quality blooms on long canes are not very plentiful. *Campanula* border Carnations are now coming in, but the American varieties spoil their sale. *Gypsophila paniculata* is seen in large heaps, a few days later it will be better in flower. *Lavender* has already made its appearance. *Statice*, in white, blue, and yellow colours, is plentiful. *Liliums* have been down to low prices. *Geraniums* and *Pyrethrums* are not so abundant. Supplies of *Irises* sold out well; the English varieties are very pretty. *Gladiolus Brechenleysis*, also the *Colvillei* varieties, *Delphiniums*, and other hardy flowers are all abundant. *A. H. Covent Garden Market, Wednesday, July 15, 1918.*

Obituary.

LOUISA CATHERINE MAYCOCK.—We regret to record the death of this lady, wife of Mr. G. H. Maycock, of Vale Royal Gardens, near Northwich, Cheshire, and previously at Luton Ho Gardens.

APPLE AND PEAR LEAVES INJURED: *L. F. and N. G., Leves.* Apple scab is present on the Apple leaves and Pear scab on the Pear leaves; spraying now will do no good, but in winter spraying must be done, and again just after the leaves are expanded in the spring, using the Bordeaux mixture at half strength.

BEGONIAS FAILING: *H. R. J.* The plants exhibit the condition known as the rust disease, which is caused by a small mite. The foliage should be dipped in tobacco water. See reply to *H.* on p. 40 of the issue of July 11.

CARNATION: Malnutrition. We cannot undertake to name varieties of Carnations, or other florists' flowers. Send to a nursery grower of these plants.

CARNATIONS DISEASED: *H. J.* The plants are infested with the stem eelworm. There is no cure for this pest, and all plants and the soil in which they have been grown should be burned. No portion of the diseased plants should be used for propagation.

CHRYSANTHEMUM-FLOWERED ASTERS: *Correspondent.* There is no microscopic agent responsible for the injury. In our opinion, something has been applied to the roots which has killed the plants.

CHRYSANTHEMUM RUST: *H. S.* Spray the plants with a solution of potassium sulphide, using half an ounce of the chemical to one gallon of water.

CLASS FOR PERENNIALS: *Hirtius.* The genus *Arenophora* is distinct from *Campanula*, and with the exception of *A. Pichleri*, which is a synonym of *C. trachelocarpa*, any of the *Arenophoras* may be legitimately shown in a class with *Campanulas* for 12 cases of distinct perennials.

IGS FAILING: *R. J.* There is no disease present that can be attributed to fungi or insects. The defect is due to some cultural error.

FORCING LILY-OF-THE-VALLEY AND TULIPS: *F. Howarth.* The necessity, in the case of the Lily-of-the-Valley, for the early forcing of the current year's crop of crowns has been considerably modified during recent years by the more general use of "retarded crowns," these responding to a bottom heat of 70°, and flowering well in about three weeks or so from the date of their introduction into the greenhouse. To obtain the best results a darkened frame or greenhouse and the above-named temperature with free supplies of moisture are necessary. In dealing with the new crowns, only those of first size should be employed for early work. Starting with a bottom heat of 63°, this should be increased to 75° in a few days, and finally to 80° or 83° as a maximum. The greatest length of flower stem is secured by plunging the crowns 6 inches deep in cocoanut fibre, the fibre to be removed when the flowering spikes appear. With the crowns well moistened when introduced and the plunging material ordinarily moist, little or no water will be required before the crop is fit to be removed from the plunging material. A darkened frame is best, and no special overhead pipe is required. The atmosphere of the house should be kept at about 60°. Three 4-inch pipes would be ample in a 4-feet wide bed with good boilers. Tulips are amenable to much the same treatment, but not Daffodils.

"FRENCH" MARKET GARDENING: *H. M.* An expert informs us that the necessary amount of capital required for working one acre of land on the "French" system, exclusive of charges for rent and water, would be £374 10s., made up as follows:—250 lights at about 8s. each, £200; 84 frames for the light at 10s. per frame, £84; 1,500 cloches at £3 per 100, £45; 300 mats at 1s. 6d. each, £22 10s.; necessary tools and implements, £10; 500 tons of manure, £125—total £374 10s. The labour bill would include wages for one experienced foreman, one assistant, one woman, and casual help when necessary. It would not be advantageous nor economical to employ hot-water pipes, as the extra cost would leave practically no margin for profit, but in the case of a private garden, where expenses are not considered so keenly as in commercial gardening, 3 or 4-inch hot-water pipes might be used, as the pipes would furnish the necessary heat when that from the manure was almost exhausted. This system, however, can only be worked successfully in the case of pipe trenches, and not by the "French" system, a garden of the area described, provided with plenty of water, would give a net profit of about £60 or £70 per annum.

GRAVES DISFIGURED: *J. H.* The injury is only superficial and the fungus is present. The herbage has probably been rubbed when thinning the bunches or during the shoots. Sometimes rubbing is caused by cold draughts or by syringing with extra force so as to remove the coating of wax known as the bloom.

GUMMING IN CHERRY TREE: *D. R.* See reply to *J. H.*, p. 40.

INSECT: *E. E.* When your box reached us it contained an empty chrysalis case and a moth which had evidently emerged from it; the latter had so beaten itself out that all the scales were knocked off the wings, and it was in such a condition that it was impossible to name it further than to say it belonged to the family Noctuidae. Perhaps it was just in the act of leaving the chrysalis that made you think it was "a peculiar insect."

MARKET GARDENERS' COMPENSATION ACTS: *J. F.* The Agricultural Holdings Act was passed in 1885, and the Market Gardeners' Compensation Act in 1895. In 1904 a new Bill was introduced in the House of Commons to remove certain doubts as to the meaning of the Market Gardeners' Compensation Act. The latest legislation affecting market gardeners is embodied in the recent Allotments Act. Any of these official publications may be obtained from the Government printers, Messrs. Wyman and Sons, Beams Buildings, Fetter Lane, E.C.

MULBERRY TREE: *S. J. S.* Shade the plant from hot sunshine, if this is possible. Spray

it overhead with clear water every evening, and again early in the morning, and do not let the soil about the roots get dry. There is nothing else you can do, but it is probable these means will help the tree to survive.

MUSCATS SHANKING: *C. F.* The trouble is probably due to a faulty border, as a check to the root system is generally the cause of shanking in Grapes. Send us an example of an affected bunch for examination.

NAMES OF FLOWERS, FRUITS AND PLANTS:—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time; they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of loss and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *Vitis*, 1, *Helenium Bolanderi*; 2, *Veronica longifolia* var.; 3, *Centaurea dealbata*; 4, *Alstromeria hamantha*; 5, *Helipopsis laevis*; 6, *Carduus heterophyllus*.—*B. H.* *Lithospermum patrum*.—*T. M.* *Phlox fruticosa*.—*H. and S.* *The Grass is Agrostis* (syn. *Apera*) *spicicaulis* (syn. *spissyrachna*) probably *S. striatum*.—*E. C. G. D.* *Elydistrum coronarium*.—*A. H.* *B.* *Lilium chalcidicum*.—*J. F.* 1, *Clematis integrifolia*; 2, *Marchantia polymorpha*.—*W. B.* *Hypericum quadrangulum*.—*H. H.* *Cymbidium aloifolium*.—*Per.* 1, *Oncidium micropogon*; 2, *Dendrobium nutabile*; 3, *Odontoglossum gloriosum*; 4, *Oncidium* (*Palumbina*) *caudatum*.—*W. T.* *Nottingham*. 13, *Thalictrum flavum*; 14, *Helenium autumnale*; 15, *Epilobium angustifolium*, white variety; 16, *Solanum jasminoides*; 17, *Trachelium majus*; 18, *Vitis heterophylla* var. *variegata*.—*J. J.* The silvery plant is *Scindapsus argyrea*; the spiny plant *Ononis spinosa*, the other *Galium Aparine*.

POTATO SCAB: *D. C.* The tubers are affected with English scab (*Sorosporium Scabies*). Lime prevents the spread of this disease, but acid manures favour it. The American scab (*Oospora Scabies*), which is much more general in this country, is favoured by the presence of lime and checked by acid manures.

ROSE BUDS TURNING BLACK: *T. W. C.* There is no disease present attributable to either insects or fungi. The injury may have arisen from one of several causes such as drought, extremes of temperature, or anything that would cause a check to the plants.

SOUTHAMPTON FLOWER SHOW:—Mr. Frank Lilley, St. Peter's, Guernsey, was awarded a Silver-Gilt Medal in this exhibition for an exhibit of early flowering *Gladioli*.

STRAWBERRIES FOR NAMING: *H. R.* In order to name these fruits it would be necessary to compare them with varieties in the garden. The fruits very much resemble those of Royal Sovereign, but the plants may differ greatly in habit from that variety. Perhaps Messrs. Austin Brothers, Bedford, or Messrs. George Bunyard, Ltd., Maidstone, may be willing to assist you. The fruits were splendidly packed and arrived in a good condition.

TOMATOES DISEASED: *E. H.* The plants are attacked by the leaf spot disease, *Macrosporium solani*. Spray the plants with the Bordeaux mixture and afford them a drier atmosphere, with an abundant ventilation.

TOMATO LEAVES: *F. H. P.* Send further examples for another examination.

TOMATO SEEDS: *H. G. G.* Select the best shaped and finest fruits generally for seed purposes. Rub the pulp and seeds in sand, allow them to dry, and then rub the sand from them over a fine mesh sieve.

COMMUNICATIONS RECEIVED:—*G. S. & Co.*, H. I. & Co., J. C. & W. B.—*E. P.*, C. J. B.—*Zola*, L. E.—*F. P.*, & Co., H. A. C.—*J. S.*, Mrs. G. J.—*L. E.*, G. J.—*P. A.*, O. M.—*R. T.*, L. F.—*F. DWARFING STOCKS—A RETROSPECT.

MANY people interested in gardening not improbably harbour the thought that dwarf fruit trees, especially dwarf Apple trees, are a modern invention, Paradise and Quince stocks an innovation dating from the nineteenth century only. Yet it is a fact, easy of verification, that dwarfing stocks have been in use in England for nearly three centuries, and it may be assumed, though it cannot be proved, for an even longer period, while it is impossible to say how far back the practice extends on the Continent. The Paradise Apple was first noticed by the French physician Ruellius, by the name of *Malus paradisica*, but it is not economically mentioned till about a century later, the authors of that epitome of sixteenth century rural pursuits, *La Maison Rustique*, failing to refer to it, though it is noted by the author of *Le Theatre d'Agriculture*, who states that espaliers were at first furnished with dwarf Apple trees called St. John.*

* Les pommiers espaliers ont esté fait des Pommiers nains dits de St. Jean.

In Brabant dwarf Apples were in cultivation some fifty years earlier, and Dodens, referring to the subject, shows that St. John was synonymous with the Paradise Apple of the French. What we know of the condition of gardening in England under Elizabeth would lead to the belief that this novel method of forming vegetative divisions could hardly escape the English gardener of that epoch, nor his master either, but not till Parkinson published his *Paradisus* is it noted by an English authority, the latter having had a hedge of Pippins and Pomewater low grafted on the Paradise stock growing by the side of a walk in his orchard. But Apples alone were not the only fruits employed to furnish these low espalier hedges, for Ralph Austin, of Oxford, an authority equally reliable with the transparently honest author of the *Paradisus*, states how it was "the custome (of late) to make Cherry hedges in gardens and orchard, and hedges of Quodlins (the Pomewater was a kind of Codlin), Miragardens, Plums, and vines." All these were arranged a yard apart, but had nothing in common in training with cordons, the shoots being twisted and plied through the trellising in order to produce a close hedge. Shears were, at least occasionally, used to prune them!

Worlidge, who was a chronicler of the horticultural doings of other people rather than a trumpeter of his own achievements, records a forward step, for in 1660 he tells those who desire to have dwarf bush fruit trees: "Let the stocks whereon you graft them be of the Paradise Apple for Apples, of the Quince for Pears, of the Morello or common Wild Cherry for Cherries—being kept low according to the new mode, though," he conscientiously informs his readers, "I see but little pleasure or profit that way." Previous to this time dwarf fruit trees had been specialised in the gardens of Hampton Court, Kensington, and elsewhere, and in Taylor's description of the *Gardens of Wilton*, "the pains and industry" of Mr. Adrian Gilbert in making "walks, hedges and arbours of all manner of most delicate fruit trees," and how he "planted certain walks and arbours all with fruit trees" is not forgotten. I think it may be concluded that dwarfing stocks would be employed in these "curiously conceived" examples of horticultural skill. Bacon indeed recommends alleys to be set with fruit trees of all sorts, but as he has not once referred to dwarf trees, we may not assume that he knew anything of them. It may, in any case, be matter for consideration that Worlidge, when he wrote, had in his mind the then well-known instances referred to above. But the Paradise which was either the original French, or the Dutch, which was also early to be introduced, was not by any means the sole dwarfing stock employed, for Codlins, Burcknots (Oslin Pippins), and other dwarf Apples were also used, and there is no doubt that they became extremely popular. So much so that, perhaps as a result of Quintiny's teaching, they were also employed for orchards, those which were laid out in the beginning of the eighteenth century being furnished entirely with espaliers and dwarf trees. The walks in kitchen gardens were at an early date bordered with espaliers, the distances from the sides of the walk varying from 3 to 6 feet.

The varieties were strictly limited to dwarf-growing dessert varieties, of which Golden Pippin, Kirton and Holland Pippins were the most esteemed and popular. The cult of dwarf trees seems to have reached its zenith in Queen Anne's time. Bradley, who (1717) epitomised the best gardening of the period, may be selected from other writers as an authority, tells how espaliers in kitchen gardens were disbudded in May, and at midsummer disburdened of superfluous shoots, and were so managed that one-third of the shoots bore fruit, one-third "knotted to blossom" the succeeding spring, and the remainder were shoots of the current year, the winter pruning consisting in the removal of the set which yielded its fruit the previous autumn. The shoots were "tied about 4 inches apart." Bradley was averse from using the knife on Apple trees, and one of the reasons he gave for recommending the Paradise stock was that Apples grafted on it bore "abundance of fruit with very little pruning." As illustrating the advanced state of gardening at this time, it may be added that he—Bradley—had known such trees "frequently cultivated in pots, sometimes so full of fruit that the Apples themselves have weighed more than the tree and the pot they grew in." It was about the beginning of this century that the Doucin was first introduced. Laurence, in 1726, states "that the dwarfing stock was introduced about thirty years previously, each tree costing 5s.," the natural inference being that he referred to the Doucin. It is quite clear that about this time the day of dwarf Apples was on its decline, and before long we read of free stocks being used for espaliers and distances adopted to plant these, each from the other, which demonstrates the suppression of the true Paradise, though the Doucin might have been used. The "Creeping," which is another name for the Dutch Paradise, also fell into disrepute, and one is hardly surprised to find dwarfing stocks condemned outright, even for Golden Pippins, in 1774. At the same time Hiitt, Gibson, Millar, and others had a good word for them, but it is obvious that the dwarf tree of their time was another thing from that of the earlier authorities. Nor must it be assumed that dwarfing stocks for both Apples and Pears fell completely into disuse because Abercrombie, Nicoll, and others recommend them merely with faint praise, though Forsyth's silence is almost as eloquent as their slightly commendatory notes. George Lindley was perhaps the first to call attention to the value of the Doucin, which again may have been neutralised by the persistent advocacy on the part of Thomas Rivers of his dwarfing stock, an advocacy which, however, had the merit of bringing the whole question again to the front, to be further popularised by Mr. Robinson's notes on French gardening and the use of dwarfing stocks in France.

These are very slight notes on this interesting subject, but they demonstrate the fact that the use of dwarfing stocks is no new thing, that the French, the Dutch, and the Doucin, besides a few dwarf-growing Apples have been long known in this country for their adaptability to dwarf trees and to promote early bearing, and so long ago as Parkinson's time it may be added that the desirability of low grafting was recognised. R. P. Brotherhood.

TREES AND SHRUBS.

XANTHORHIZA APIIFOLIA.

This is a comparatively unknown shrub in gardens, although it was introduced into cultivation as far back as 1766. The plant is of considerable interest, for the foliage is ornamental and the inflorescences are pretty, though the individual flowers are small. It is a native of North America, being found in various states from Pennsylvania southwards to Florida, whilst in Carolina it is very common. In a state of nature it is found growing in shady places in moist ground, frequently in woods, or on the margins of streams. Under cultivation it grows from 1 to 2 feet in height. The leaves are bipinnate and arranged in tufts at the extremities of the branches, and vary from 3 to

ERICA AUSTRALIS.

The early-flowering Heaths form a very ornamental group of shrubs, and are worthy of cultivating on an extensive scale, for they rarely fail to produce an abundant crop of flowers during the early months of the year. *Erica australis* is one of the least known, though, according to Aiton, its date of introduction was 1769, the introducer being given as the Earl of Coventry. It is probable that it lost favour with horticulturists through being somewhat tender, for it is unable to withstand very severe frost, though 16 degrees does not harm it. Although it belongs to the section known as Tree Heaths, it is one of the dwarfest of the group, and never attains to the size of such species as *E. arborea*, *E. mediterranea*, *E. lusit-*

NOTES FROM A "FRENCH" GARDEN.

MUCH time is now required for examining the fruits of Melons to ascertain which are ripe, as during dull weather many are mature whilst the skin is still green.

We have now planted Cauliflowers amongst the old batch of Melons, except in the case of those which were planted in June: in this case we shall plant the Cauliflowers in a fortnight's time.

Endive has benefited greatly by the recent rains, and the plants are now thoroughly established in their new quarters. We are also planting Cauliflowers amongst this crop, placing one Cauliflower between every two Endives in the rows 1, 4, 7, and 10. As it is necessary to tread on the beds when planting the Cauliflowers, a very dry day has to be chosen for the operation.

Celery promises well, and up to the present this crop has required very little watering. We have cleared all the Cauliflowers which were planted next to the batch of early Cos Lettuces, and the ground has been dug. We have sown "Bellot" Carrots and Spinach as a catch crop. These will both require copious waterings in order to obtain good results.

Persons intending to start this system of gardening should order all necessary lights, cloches, mats, and other implements at once. If the lights are ordered from France, it should be specified that the sashes must be capable of taking 12-inch wide glass, for if this is not pointed out, they will be made to take the French glass, which is half-an-inch less in width than the English glass. There is only one type of cloche made for the intensive culture of vegetables, and they are known as *cloches maraichères*. They are 17 inches in diameter and 15 inches in height, but they may vary slightly in the casting. They should be ordered in crates holding from 200 to 300 cloches, for then they can be lifted by machinery, which saves many breakages that often occur when they are bundled about by hand. All the implements, including lights, mats, cloches, etc., should be delivered by September, as the cloches are needed at the end of that month, and if the glazing of the lights is to be done on the premises this will allow ample time for them to dry before they are wanted for use in January. The ground for a French garden should be chosen in a well-sheltered spot, having a gentle slope from north to south and close to a main road. An abundant supply of water is very essential. A fence or wall 6 to 8 feet high around the garden will be found very useful. The ground should be levelled and heavily manured if the crops are intended to be grown in the open. *P. Aquatias, Mayland, Essex. July 15.*

SEMPERVIVUM HOLOCHRYSUM.

In Mr. Howard Fox's wonderful garden at Rosehill, Falmouth, numbers of rare and tender plants are grown, and it is impossible for a flower lover to visit it at any season of the year without being impressed with the treasures it contains. A remarkable plant that was in flower in the spring three seasons ago was *Sempervivum holochrysum*, a native of Tenerife, and classed by Nicholson as a greenhouse plant. At Rosehill, however, it was growing vigorously among the stones at the edge of a path, and was blooming superbly (see fig. 24). The great, yellow flower-heads were 15 inches in height and 43 inches in circumference, and the height of the flower-stems was 3 feet 6 inches. It presented a striking sight, with its enormous, golden flower-clusters borne on tall stems above its spreading, succulent foliage, and was quite one of the most interesting features of the beautiful garden at that time. It is probably not grown in the open anywhere else in England, and, being a rare plant, is seldom seen even under glass. *S. W. Fitzherbert.*

FIG. 24.—SEMPERVIVUM HOLOCHRYSUM.

6 inches in length. The flowering period is late March and early April: the flowers, which are small and purple, are borne in graceful, drooping panicles from the ends of the leafless branches. It is known in the United States under the name of Yellow Root, a name given on account of the Saffron-yellow colouring of the root and stem. According to Small's *Flora of the South-Eastern United States*, the local name of Brook Feather is also applied to it in some places. A figure of the plant is given in Bentley and Trimen's *Medicinal Plants*, vol. i., fig. 9, and the roots are there stated to possess similar qualities to quassia. If given loamy soil, and a fairly moist position, it grows readily and increases rapidly by means of underground stems.

tanica, &c. Under cultivation in the London district it attains to a height of 3 to 4 feet, but this may be doubled under favourable conditions of soil and climate. The growth is loose and rather straggling, in which it shows a distinct contrast to other species. The leaves are dark green, the flowers, which are red, are larger than those of any other hardy Heath, and for this reason, when growing in company with *Ericas*, the plant, when flowering, is very conspicuous. Though it never forms such a dense growth as other species, repeated stopping of the shoots when young causes a denser growth. *Erica australis* is a native of Spain, Portugal, &c., and has been spoken of as the "Spanish Heath." The plant flowers in April. *W. D.*

THE ALPINE GARDEN.

THE PORPHYRYON SAXIFRAGES.

IN the case of Alpine plants there are many small but essential cultural points which require attention if success is to be attained. Among the Saxifrages there are some which require peculiar treatment, and one section which gives much trouble to many is that known as the Porphyron, or oppositifolia class, well known and hardly requiring any description, seeing that Saxifraga oppositifolia, which may be taken as the type of the whole, is fairly familiar to all cultivators of Alpine plants.

In cultivation it and its allies are almost certain to become brown in the centre and die off after being a year or two in the same position, although in some places there are good plants which have gone on for a few more years, but even these eventually become lost in the same way. Many have dreams of large sheets of these brilliant little flowers, but such can only be secured by planting together a number of smaller plants and by keeping up a steady system of division and propagation. Only the other day I saw good patches of *S. oppositifolia* and its variety splendens, and it seemed hard to advise the owner to tear these plants to pieces in order to secure their maintenance in health. Yet it was essential to do so, and it is this process of breaking up and replanting these forms which is absolutely necessary if one's stock of these charming little Alpines is to be retained. It is even more useful with some of the finer forms of *S. oppositifolia*, such as *pervenica* and splendens, and this operation should be performed every two years or so.

The best time to carry it out is during showery weather immediately after the flowering period, lifting the plant and tearing it to pieces about an inch or two across, replanting the pieces in similar soil to that recommended below, and watering well until established. Top-dressing with grit and leaf-soil will oftentimes prolong the life of a plant, but whenever the signs of browning in the centre are visible it is doomed unless the process of division is adopted at the proper season. Indeed, it would be better to do this in August than to leave the plant alone. I have always found these Saxifrages do best in a place exposed to the sun and in a compost made up of loam, sand, and grit in about equal parts. They are greatly assisted by copious drenchings with water during warm, dry weather in spring and throughout the summer. It is well to put plenty of broken stones about the plants, sandstone being preferable on account of its capacity of absorbing moisture, and thus assisting the plant during dry weather.

ASPERULA HIRTA.

THERE are many beautiful things among the Alpine *Asperulas* or *Woodruffs*, but I do not know of any one which is more generally admired when it is well cultivated than *Ramond's Asperula hirta*, from the Pyrenees. It has been in cultivation since 1817, but appears to be rather rare, although it is not at all difficult to grow in the open. A book of much value tells us that it thrives "best in a rather damp position on the rockery," but this depends greatly upon the amount of rainfall in the district, and it does not require, as a rule, any special consideration in this respect, seeing that it will grow in almost any soil and in a situation exposed to cold winds, and where there is a dry instead of a damp soil. I have one of my plants high up in my rock garden and in pots, dry, stony soil, and this one is growing and flowering quite as well as one lower down and in a position more in accordance with the suggestion in the book already referred to. I see, also, that M. Correvon, in his excellent little

work, *Les Plantes Alpines et de Rocailles*, names it among the plants which form this class one for cultural treatment, these being of easy culture and requiring nothing special in the way of soil. This is quite in accordance with my own experience, and I have for some time ceased to use peat in the soil in which this *Asperula* is cultivated, finding that it is much more satisfactory when in hardy, poor, stony, and gritty earth. The portion of the rock-garden where it is best with me is simply formed of the soil excavated from the foundations of my house, and of a hard and gravelly nature, and without any addition of peat, leaf-mould, or even good loam.

Asperula hirta forms a compact, little Moss-like mound of rather hairy foliage, seated on which are little heads of tiny flowers which open whitish, changing soon to pink, and making a delightful subject for the Alpine garden. This *Asperula* is best increased by division. *S. Arnottii*, *Sammoyad*, *Dumfriesii*.

CALATHEAS.

IT is probable that many years will elapse before the beautiful foliage plants long known in gardens as *Marantas* will be recognised by another name, though botanists now include them in the genus *Calathea*.

In the days when stove foliage plants were in great popularity, *Calatheas* were general favourites because of their handsome leafage. I well remember the excitement caused by the introduction of *C. Veitchii*, a plant first introduced by Richard Pearce, of tuberous *Begonia* fame, and distributed by Messrs. Veitch as a new plant in 1866. With the exception of the distinct and showy *C. zebрина*, which was sent from Brazil in 1815, *C. Veitchii* is one of the oldest introduced species and also one of the best. Since its introduction many other *Calatheas* have been put into commerce, nearly all of which are natives of the tropical portion of South America.

A species that at once arrests attention by reason of the almost indescribable colouring of the foliage is *C. Massangeana*—the markings of the leaves have been compared with those on the wings of some butterflies. A prominent feature of the foliage is the large blotches of a dark velvety purplish-maroon set on a comparatively light ground. *C. Massangeana* has a low-spreading habit of growth, and under favourable conditions it grows freely. The genus *Calathea* is a fairly extensive one, so that in most gardens a selection is necessary. The following, with the particulars of their foliage, are all good and distinct kinds:—*C. hieroglyphica*, dark velvety green ornamented with streaks of silvery-white, undersides purple; *C. illustris*, bright green marked with deep green and white; *C. Kerchoviana*, greyish-green with a row of chocolate blotches on each side of the midrib; *C. leopardiina*, yellowish-green with irregular blotches of deep green; *C. Makoyana*, deep green and white; *C. Massangeana*, already alluded to; *C. roseo-lineata*, olive-green leaves with pink lines; *C. Sanderiana*, a bold-growing plant whose leaves are of a dark olive-green marked with white lines and rich purple underneath; *C. Veitchii*, an erect-growing plant having large leaves of a rich glossy green, marked with crescent-shaped blotches of yellowish-green; *C. Warszewiczii*, large leaves of a velvety green, relieved by a feathery stripe of yellowish-green on either side of the midrib; and *C. zebрина*, of a light velvety green banded with purplish-green.

In addition to these there is a comparatively new species, viz., *C. usneifolia*, a fine specimen of which formed a very striking feature in Messrs. James Veitch & Sons' group of stove and greenhouse plants at the recent Temple Show. This species has long, partially erect, lanceolate-shaped leaves, of a light green colour, deeply

shaded on the margins, and ornamented with dark velvety blotches on either side of the midrib. The under surface of the leaf is coloured a rich purple. The leaves are longer in proportion to their width than in any of the other *Calatheas*, being about 15 inches long and 2 inches wide at their broadest part.

The *Calatheas* belong to the natural order Scitamineae, or, as they are popularly termed, Ginger Worts, but unlike many of their congeners, the flowers cannot be termed showy. Perhaps the most noteworthy for the beauty of its blossoms is *C. crocata*, which was given a First-Class Certificate by the Royal Horticultural Society on February 8, 1881. I have not seen it for some years, and cannot say if it is still in cultivation.

The conditions under which the different *Calatheas* occur in a state of nature must be borne in mind in their cultivation, for they grow generally in forests, and consequently vegetable debris form their principal rooting medium. Like most plants that grow in this manner the root system is shallow and wide-spreading rather than deep and descending. For this reason when they are grown in pots a liberal amount of drainage material is necessary, for they need copious supplies of water when actively growing, but they are impatient of stagnant moisture. Where provision exists for planting them in borders in the stove these *Calatheas* are well suited for forming an undergrowth or as edging plants. When cultivated in pots a suitable compost is formed of equal parts of loam, leaf-mould, peat, and sand, the whole being pulled to pieces with the hand and not sifted, as by this means an open porous compost is ensured. Repotting and division is best carried out in the spring before growth recommences. As much as possible of the old soil should be removed, for the fresh roots will soon take possession of the new compost. As the sun gains power shading is necessary, and a liberal amount of atmospheric moisture must be maintained, otherwise the leaves are liable to attacks of red spider. J.

COLONIAL NOTE.

TRANSVAAL FLOWERS.

WRITING under date June 21, 1908, Mr. Jas. Hall, The Rosary, Johannesburg, says: I have before mentioned to you the beauties of the *Roses* here and the profusion with which they produce their flowers, some of our old kinds, such as *Archimède*, producing a sheaf of flowers for every one seen on the ordinary *Rose bush* in England. Nevertheless we get the newer sorts, and they are very satisfactory. *Carnations* grow and bloom beautifully. The old stock by propagation sometimes wears out, and for the last few years I have been very successful in raising fine doubles from seeds obtained from Mr. Jas. Douglas, and these have a good constitution and produce fine flowers. After one of the finest autumns I remember, winter has now commenced, and it has lately been very cold, windy and dusty, for we have had no rain for several weeks. At this season dry weather is best, although we have to keep all growing crops moist by irrigation. This is done early in the morning so as to give our never-failing beautiful sun the chance to dry the earth before nightfall and thus escape damage by frost, which is often severe towards morning. This season, so far, nothing has been damaged by frost except *Dahlias* and other tender plants of that class. Five years ago, earlier in the year than this, frost came so suddenly and severely that it killed hundreds of my *Carnations* that were 2 feet high, and many other tolerably hardy plants, including quantities of *Car. Andrieuxii*, perished. This year the *Violets* are still blooming beautifully.

CAMPANULA CARPATICA VAR. PELVIFORMIS.

This beautiful Campanula is held by some to be a distinct species, but there is little doubt that it is merely a form of *C. carpatica*. Certainly, as far as its flowers are concerned, it might well rank as a species, for there is nothing in them to indicate a relationship to *C. carpatica* but in the foliage it is different, for this is practically identical with that of *C. carpatica*. Another conclusive proof of its parentage is that seedling plants are never like their parent, but revert more or less to the typical *C. carpatica*. The original plant was raised by Herr Fröbel. Its flowers are pale lavender in colour, saucer-shaped and about 2 inches across, being totally distinct from the bell-shaped blossoms of the common *C. carpatica*. It is a charming plant of a stiff, firm habit, with freely-branching stems about a foot in height. Among the members of the Campanula family none is more distinct and worthy of culture. It will commence to bloom when only 3 inches in height, and as it increases in size will afford a finer display each year. It should be found in every collection of hardy plants, for it is certainly one of the best of its class, and is both compact and free-flowering. Its erect and sturdy habit prevents the blossoms from being beaten down by the rain. Those who are not acquainted with it would be surprised at the length of time during which it continues to develop its softly-tinted flowers, for during many weeks in the summer it is a cloud of lavender. It is better suited to the rock-garden than to the border proper, and does best in light, rich soil, wherein the root-fibres may feed and move freely. It is, however, by no means an easy plant to keep, as it has an unfortunate habit of dying out in many gardens, but it is so beautiful that it should be tried again and again in spite of reverses. *S. W. Fitzherbert.*

THE ROSARY.**SOME EARLY-BLOOMING CLIMBING ROSES.**

PROBABLY no Roses are more esteemed than those which announce the approach of summer, and blossom in advance of the great flush of the Rose season. I venture to give a few notes on those that are in full beauty at the end of June, varieties which are extremely effective as pillars or arches or for pergolas:—

Morgonroth, the perpetual-blooming carmine pillar, is one of the earliest to unfold, and its lovely single carmine-red flowers with white bases render it one of the best in this section.

Uma, a lovely single flower with the faintest of blush edges and golden anthers, forms a perfect arch, and is not surpassed by any variety of the same colour.

Ards Pillar is a superb, richly-scented crimson Rose, which is the finest of the dark Roses for a climber in any form.

Leucistern makes a stiff, full, and perfectly filled arch, carrying many thousands of its bright, single, cherry-pink flowers with white centres in clusters of 10 or 12. Its effect is very striking and lasting.

Rosa moschata nivea.—The flowers are white with the faintest blush, produced in elegant clusters, a perfect single flower for an arch, and its silvery-green foliage is an additional charm.

Aglais, a soft primrose double flower, produced in clusters most freely. This is a very vigorous grower, and a perfect galaxy of loveliness when in perfection. It sends up shoots 8 to 10 feet in a year, and my largest plant is trained in three directions for 20 feet, and is the admiration of all visitors.

The Wallflower.—This is a double rosy-red flower; it makes a compact pillar, and is of a shade of colour unusual in this class.

The Lion, a single crimson of a fascinating shade with a white centre. The plant forms a close pillar, and is most striking.

Jersey Beauty, a lovely single flower of primrose colour shading to white. The plant is of vigorous growth, and has the bright shining foliage of the Wichuraiana breed. It is excellent also as a carpet creeper.

Alberic Barbier, a creamy white and yellow double form of the Wichuraianas, and a most beautiful variety.

François Crousse, rich crimson in clusters, flowering all the season, very vigorous, a Hybrid Tea of great merit.

Reni André, a double salmon-rosy Wichuraiana variety, elegant in bud, and most profuse in flowering, a shade of colour greatly admired.

Claire Jacquier, a Polyantha variety, producing double primrose flowers with yellow centres in loose clusters, a rampant grower of great beauty.

Electra, primrose and yellow, with larger flowers than those of *Claire Jacquier*. The plant forms a pretty close pillar, and is one of the best hybrid Wichuraianas or Polyanthas.

The Dawson.—This variety flowers very early, and produces hundreds of lilac-rose blossoms in

Roses are now so interbred that it is difficult to place them in any class, but the word "Roamers" would cover all that are suitable for climbing over old trees, on arches or pergolas, the less vigorous growers being used for pillars.

As July lengthens, other most desirable varieties commence to blossom. In the crimson varieties we have Philadelphia, deep in colour and glowing in effect; Crimson Rambler, the exquisite single crimson Hiawatha, Rubin, with its purple foliage, and the vigorous, large-flowered Mme. Ernest Levavasseur, Mme. Isaac Pereire, Noella Nabonnand, the latter finely scented but erratic in growth, carrying large clusters at the end of 2 feet shoots.

In pink and rose colours there are Dorothy Perkins, still our best, and its more elegant form, Lady Gay, Mrs. Flight, Blush Rambler, and the lovely Tausendschön.

In softer shades, Psyche, Helene, Debutants, and Minnehaha, and the lilac-rosy Queen A. exandra.

In white varieties we get Trier, Waltham Bride, Snowstorm, and Perle des Neiges.

FIG. 25.—CAMPANULA CARPATICA PELVIFORMIS.

loose clusters. It is a fine Rose for an arch or pergola.

Lady Waterlily, a hybrid with fine foliage. It makes a good pillar, and flowers twice in the season. The blossoms are large, white in centre, with a lovely shade of peach and rose at the edge. It also forms a good bush in the garden.

Gustave Regis, a primrose-coloured flower, with yellow base in the bud state, but semi-double white or faintest primrose when open, with clusters of anthers in centre. A pearl of the first water, and a Rose for an artist.

Rosa macrantha, white and palest blush, with gold anthers, an exquisite single variety.

Thalia, with snow-white rosette flowers produced in conical clusters, effective and early.

I might mention that all these, and especially the "Wichuraiana" varieties, make useful subjects for pegging on banks or to clothe unsightly spots. Their culture is very simple, merely cutting out the old wood in winter and disposing the long new shoots where required.

In coppery and orange shades Marco, Goldfinch, Crepuscule, and the grand Noisette William Allen Richardson.

At the same time we must not overlook the old Ayrshire evergreen climbers, as the rampant Mme. d'Arblay, 20 feet up a tree in my garden, with big white clusters, the rosette-white Félicité Perpetue, the cluster whites, Bennett's Seedling and Amee Vibert, with snowy masses of blossom, Brunonii, with silver-green leaves, Dundee Rambler: the blush cluster varieties, as Williams' Evergreen, Princess Marie, Myriantes, and Wells' Pink.

I propose to deal with the larger-flowered Roses, suitable for pillars, &c., such as the Dijon and climbing hybrids in a future paper, but I can fully recommend all the kinds I have now named.

For early blossom in mid May, the Briar Roses Fragrantissima, single primrose, and Horace orange-yellow, are very effective as bushes, coming as they do before even the China Roses. *George Bunyard.*

FLOWERS OF SPENSER.

(Continued from p. 45.)

HELLEBORE.

Dead sleeping Poppy and black Hellebore.
F.Q., II. vii. 52.

Black Hellebore was the established classical name for many poisonous plants. It is now restricted to our Christmas Rose, which, though not a British plant, may have been known to Spenser, as it was introduced into English gardens in very early times.

HOLLY.

Leave me those hilles where harbrough nis to see,
Nor holly-bush, nor breere, nor winding ditch.
Shepherds Calendar, June, 10.

Of course our beautiful English evergreen.

HOLM.

1. The carver Holme. *F.Q., I. i. 9.*
2. And the black Holme that loves the watrie Vale. *Virgils Gnat, 27.*

The word Holm was variously applied by the old writers to the Oak, Holly and evergreen Oak or Ilex. In the first passage I suppose Spenser means the Holly. The whole stanza relates the uses of the different trees, as the Pine for shipbuilding, the Oak for building, the Yew for bows, and so the Holly for making the handles of knives or carvers. In the second passage he would mean the evergreen Oak or Ilex; but he could not have had much personal knowledge of it, or he would not have spoken of it as loving "the watrie vale." It is certainly not a water-loving tree; in Southern Europe it is often seen growing out of the bare rocks.

HYACINTH.

1. Fresh Hyacinthus, Phœbus paramoure,
And dearest love. *F.Q., III. vi. 45.*
2. The purple Hyacinthe, and fresh Costmary. *Virgils Gnat, 84.*

The Hyacinth of the Elizabethan poets was our Bluebell of the woods, but in these two passages Spenser is simply copying and translating Virgil.

HYSSOP.

Sharpe isopie good for greene wounds
remedies. *Mutopotmos, st. 24.*

The Hyssop was a favourite plant in English gardens in Spenser's time, but I do not find in the herbals of the day any reference to its use in "greene wounds." It is a native of Southern Europe.

IVY.

1. Whylst freshest Flora her with Yvie girlond crowned. *F.Q., I. i. 48.*
2. And on his head an Yvie girlond had. *F.Q., I. i. 48.*
3. And with an yvie twyne his waste is girt about. *F.Q., I. vi. 14.*
4. An Arbre green dispreed,
Framed of wanton Yvie, flourishing fayre. *F.Q., I. vi. 29.*
5. A wandring Yvie
Enchaced with a wanton yvie twine. *F.Q., II. iv. 24.*
6. And over all of purest gold was spred
A trawle of yvie in his native hew;
For the rich metal was so coloured
That wight, who did not well avise'd it vew,
Would surely deeme it to bee Yvie trew. *F.Q., II. xii. 61.*
7. Which knitting their rancke braunches, part
to part,
With wanton Yvie-twyne entrayled athwart. *F.Q., III. vi. 44.*
8. His waste was with a wreath of Yvie greene
Engirt about, no other garment wore. *F.Q., IV. vii. 7.*
9. And nigh thereto a little Chappel stodee
Which all with Yvy overspred
Deckt all the roof. *F.Q., VI. v. 35.*

10. And over them spred a goodly wilde Vine,
Entwailed with a wanton Yvie twine. *Shepherds Calendar, August.*
11. And girt in girlands of wild yvie twine. *Shepherds Calendar, October.*
12. Amongst the rest the clambing Yvie grew,
Knutting his wanton armes with grasping hold. *Virgils Gnat, 28.*
13. And pallid Yvie, building his owne bowre. *Virgils Gnat, 85.*
14. At length within the Yvie todde
I heard a husie bustling. *Shepherds Calendar, March.*

In all these passages Spenser shows no appreciation of the beauty of the Ivy. In all of them he connects the plant more or less with revelry and licentiousness, so showing that he was copying the classical association of the Ivy with Bacchus and Silenus.

JASMINE.

Her nipples lyke young blossomsd Jessa-
mynes. *Amoretti, 64.*

The Jasmine was introduced into England from Southern Europe about thirty years before Spenser wrote. It is not, however, a true European plant, and the name seems to show that its native home is Arabia.

JUNIPER.

1. No tree, that is of count, in greenwood
groves,
From lowest Juniper to Cedar tall. *F.Q., IV. x. 22.*
2. Sweet is the Junipere, but sharpe his boughe. *Amoretti, 26.*

The Juniper was, no doubt, a much commoner shrub on our hillsides in Spenser's time than it is now. It is found more or less all over Great Britain.

KINGCUPS.

And cowslips and kingcups and loved lilies. *Shepherds Calendar, April.*

A very old name for the Marsh Marigold, and still in common use.

LAUREL.

1. But now they laurell braunches bore in hand;
Glad signe of victory and peace in all their land. *F.Q., I. xii. 5.*
2. The Laurell, meed of nightie conquerors,
And Poets sage. *F.Q., I. i. 6.*
3. That Fame may it recount,
In her eternal tromp with laurell girlond
cround. *F.Q., II. iii. 38.*
4. And all the margent round about was sett
With shady laurell trees. *F.Q., II. xii. 63.*
5. Beside the same a dainty place there lay,
Planted with myrtle trees and laurells
greene. *F.Q., III. v. 40.*
6. Daunst lively and her face did with a law-
rell shade. *F.Q., III. x. 44.*
7. A grave personage
That in his hand a branch of laurell bore. *F.Q., III. xii. 3.*
8. Lawrell th' ornament of Phœbus toytle. *Virgils Gnat, 84.*
9. The fresh and lustie Lawrell tree. *Visions of Petrarch, 3.*
10. And head with Lawrell garnisht was about. *Visions of Bellay, 6.*
11. The laurel-leave, which you this day doe
weare. *Amoretti, 28.*
12. Like Yvrie Queenes with laurell garlands
cround
For virtues meed and ornament of wit. *Tears of the Muses, Terpsichore.*
13. The woods with Paphian myrtle peopled
To laurels sweete were sweetly married. *Britains Ida, 2.*

Spenser's Laurel in all these passages was not the shrub which we now call Laurel, but the Bay tree. And all the references are to the classical associations of the Laurel with the crowns of conquerors, except in No. 12, where the association with virgin queens re-

calls Ovid's *immba laurus*, because the virgin Daphne was turned into a Laurel. The Bay, both tree and name, was well known before Spenser's days, but the name was more given to the berry than the tree. (See also Bay.)

LAVENDER.

The wholesome Saule and lavender still
Spenser's Lavender was the same as our own. *Mutopotmos, st. 24.*

LETTUCE.

Cold lettuce and refreshing Rosmarine. *Mutopotmos, st. 25.*

LILY.

1. He led a lovely maid
Forth by the Lilly hand. *F.Q., Canto iii., 37.*
2. On a sweet bed of Lillies softly laid. *F.Q., II. v. 32.*
3. The Lilly, lady of the flowering field. *F.Q., II. vi. 10.*
4. And that faire flowre of beaute fades away,
As doth the lilly fresh before the sunny ray. *F.Q., III. vi. 35.*
5. As roses did with Lillies interlace. *F.Q., V. iii. 23.*
6. But if her like ought on Earth might read,
I would her liken to a crowne of Lillies
Upon a Virgin Brides adorned head. *Colin Clout, 236.*
7. Cowslips and Kingcups and loved Lillies. *Shepherds Calendar, April.*
8. The Lilly fresh and Violet belowe. *Virgils Gnat, 84.*
9. Seest how fresh my flowers bene spredde,
Dyed in Lily white and Cremsin redden. *Shepherds Calendar, February, 129.*
10. With rose and lilies over them displayed. *Hymnes, 280.*
11. And with sweet kisses suckt the wasting
breath
Out of his lips like Lillies pale and soft. *Astrophel, 115.*
12. It soft doth lie,
In a bed of Lillies wrapt in tender wise. *Clorinda, 70.*
13. Her heart sent drops of pearls which fell
in foysion downe
Twixt Lily and the Rose. *Mourning Muse, 97.*
14. The rose and lily have their prime. *An Elegie, 137.*
15. Her goodly length strecht on a lily bed,
Few roses round about were scattered,
As if the lilies learnt to blush, for sight
To see a skinne much more than lilly-white. *Britains Ida, III. 2.*

In these passages Lily has more than one meaning. In some it stands for any beautiful flower, as in the "Lilies of the field" in the Gospels; in others it merely stands for a colour; but in others there is no doubt that some special Lily is meant. There is no Lily truly native in England, but in Spenser's time several from Southern and Eastern Europe were common in English gardens; the most common being the White or Madonna Lily. As in all the passages, its whiteness is especially mentioned, and so it is taken as the emblem of purity and beauty; I should suppose that this is the Lily that Spenser had in his thoughts, and there is none more beautiful.

LOTUS.

And them amongst the wicked Lotos grew,
Wicked for holding guilefully away
Ulysses men, whom wrapt with sweetenes
new,
Taking to hoste, it quite from him did
stay. *Virgils Gnat, 24.*

Spenser is quoting from Homer's account of the food of the Lotophagi. It is not certain what tree Homer meant, but the general opinion is in favour of the Jubube tree (*Zizyphus lotus*). *H. N. Ellacombe.*

(To be continued.)

GRIMSTON PARK, TADCASTER.

ALTHOUGH the post town is Tadcaster, Grimston Park is situated in the Yorkshire village of Kirkby Wharfe, and the visitor from York, about 11 miles distant, alights at Ullselt station, the journey to the park being about 1½ miles along a pretty country road. Grimston Hall is a commodious mansion, built in the Italian style of architecture, the main front having a handsome balcony supported by Doric columns, and with wings at either end. There are two towers, which add dignity to the building, and the roof is surrounded by balustrades with ornamental vases at intervals. Stonework is freely employed in the building, magnesium limestone being abundant in the district. It was from the neighbouring village of Towton, famous for its battle in 1461, described as the bloodiest and most fatal fought on English soil since the battle of Hastings, that much of the stone employed in the building of York Minster was quarried. The present mansion was built on the site of, or rather incorporated with, an older building, by the late Lord Howden. Subsequently it passed into the possession of Lord Lonsborough, from whom it was purchased by the late J. Fielden, Esq.,

almost as fresh as when they left the sculptor's studio. In the winter season they are carefully enclosed with wood, and thus frost, which exerts such an injurious effect upon stonework, is in a great measure excluded. With regard to the flower garden at this spot, it is intersected by several broad and well-kept paths, which are in part lined with standard Rose trees, the flower-beds being formed in a setting of turf, and there are many half-circular clipped trees of Holly. The flower-beds form a series of panels, the larger ones having a circular centre bed and two of oblong shape north and south. These beds are filled in summer-time with a variety of plants, including Zonal and Ivy-leaved Pelargoniums, Begonias, Centaureas, Saivias, Calceolarias, &c., and others are furnished with sub-tropical bedding. The whole forms a pretty parterre garden, and in summer-time it affords a beautiful setting to the handsome south front of the residence. The best Pelargonium to succeed is the fine Guillian Manglesii variety, that in summer-time furnishes a gay picture with its showy flowers. At the western end of the Hall is a large conservatory, 60 feet long, having a dome in the centre of an iron roof, and with stone dressing to the exterior walls, in harmony with the main building. This conserva-

temple containing a laurel-crowned bust of the first Emperor Napoleon. The avenue is entirely shut in on either side by tall trees, a strip of turf on either side, with the broad path in the centre, only separating the trees; but the latter are undulating, so that the avenue is not too formal. A little to the south of this statue-lined walk stood the famous old Sycamore that was illustrated in our issue for October 8, 1881, p. 469. This was indeed a monarch of the forest: it measured 21 feet in circumference at 4 feet from the ground, the lowest limb extending 44 feet from the bole. The tree branched into four main stems. It was found necessary to remove the tree in December, 1896, as owing to injury by storms and from decay, it was considered unsafe and liable to fall. At this spot are two replicas of classical statues representing lions attacking a horse and a bull.

Near this spot the woodland scenery is enchanting, and many fine Copper Beeches and Golden Vews add a touch of colour to the scene; the path winds beneath the canopy of trees, and shrubs play their part in forming border lines to the walks, formal outlines being avoided. Our attention was directed at this spot to the turf which borders the paths. Growing in abundance, in company with the grass, was *Selaginella denticulata*. This has established itself, and is, apparently, perfectly hardy—a remarkable fact, seeing that Yorkshire does not enjoy a climate free from severe frosts. Its presence is accounted for by the use of old potting soil when transplanting some shrub or tree. In the conservatory there were for many years marginal boxes filled with the plant in question, which require replanting every few years. The old soil was always wheeled to a heap not far away. There can be no doubt the plant propagated itself from spores or fragments of the plants in this soil when used for the purpose above-named.

In one part of the grounds near to the house is a sunken dell, wild, but beautiful in its aspect, with native Ferns scrambling up the sides. This would form an ideal spot for a rock-garden, although some of the overhanging trees would have to be sacrificed, as it is quite shaded over by their branches. There is also a fine border planted with hardy plants, and against a wall are Roses and flowering shrubs. On the opposite side of the path are beds of Roses, and in summer-time this walk is one of great beauty. From it is reached the walled enclosed garden devoted to fruit and vegetable culture.

This kitchen garden occupies a favoured position, and the crops are, on the whole, considering the very cold weather of the past spring, doing well. Culinary Peas, on the occasion of our visit, gave promise of fine crops. The variety Iangley Gem always furnishes abundant pods; others favoured are Acme, Criterion, and Prestige. There were large breadths planted with Brussels Sprouts. Cauliflower Dean's Snowball, sown in January, produces fine heads, and this is followed by Early London; Onions, Carrots, Beet, Potatoes, &c. Of the last-named, Sharpe's Express and Duke of York, on a south border, were especially good. There is a fine old tree of Marie Louise Pear on a north wall, some of the branches being trained over on to the south side. This tree was carrying a good crop of fruits, but most of the other Pear trees were sparsely fruited. The best Pears to succeed are Louise Bonne of Jersey, Jargonelle, Williams' Bon Chretien, and Pitmam's Duchesse. Apples did not promise a heavy crop, but a tree of Warner's King rarely fails to fruit heavily in these gardens. Others noticed were Lane's Prince Albert, Lord Suffield, Margil, Potts' Seedling, Ribston Pippin, and Claygate Pearmain. Peaches and Nectarines in the open in some seasons give good crops. Plums also do well generally; but this season, in common with trees in most gardens, the crop of this fruit is thin. Varieties that succeed here are Greengage, Coe's Golden Drop, Pond's

FIG. 26.—GRIMSTON PARK HOUSE, TADCASTER.

the present owner being Mrs. T. Fielden. The park embraces about 600 acres, the elder Nasmyth being responsible for its laying out about 70 years ago. The main entrance is near to the highway, and an old toll-gate, which is said to have been cleared by the outlaw Dick Turpin on his horse during his famous ride to York, stood not far away. This is on the north side, but the principal front faces to the south. The entrance gates are of iron, finely wrought, and with two large heads, graven in stone known as the "Kings of the Forest," on the two main pillars. A circular lawn is bounded by the carriage drive.

Grimston Park is famous for two features—its beautiful sylvan scenery and its garden stuary. Were little attempted in the way of pleasure gardening, the spot would still be one of great beauty on account of its natural features; but much has been done to make the grounds additionally attractive, especially the garden front to the mansion, which is a broad expanse, well designed and boldly planted. It is here that most of the beautiful statuary already alluded to is found, and they are so carefully preserved that at present they show little traces of damage from the climate, and appear

tory communicates with the dwelling rooms, and in summer-time forms a cool retreat. It is furnished with Palms, including two fine specimens of *Raphis flabelliformis*, a number of rock climbers, such as *Tacsonias*, *Asparagus* and *Roses*, and large hanging baskets of *Stenotaphrum americanum variegatum*. Planted out is a large tree of *Acacia dealbata*, that must be of great age. Flowering plants in pots afford a touch of colouring to the Palms, Ferns, and other greenery. Near the entrance to this plant house is a sunken lawn that is now used for croquet and other games, its limits being planted with standard Rose trees. This was originally a flower garden, designed in keeping with the flower-beds facing the front of the mansion. Further on still is a large water basin, with a beautiful vase rising from the centre. The basin is spacious and planted with showy flowering *Nymphæas*. Continuing the walk to the west, past fine woodland scenery, the visitor approaches a spot known as the Emperors' Walk (see fig. 27). This name is given on account of the series of busts of Roman Emperors on pedestals which line the walk. There are 12 in number, and between each is a shapely specimen of Irish Yew, and at the far end a

Seedling, and Victoria. Of Strawberries, Royal Sovereign is largely planted, and is used extensively for forcing, but President is the heaviest cropper. Louis Gauthier is another favourite variety at Grimston, where it grows and fruits well.

The glasshouses, including the large conservatory, number 23. Three are vineries, the same number Peach-houses, and others are used for the culture of plants, Figs, Melons, Tomatos, Cucumbers, &c. Four houses are devoted to the culture of Carnations, principally of the Souvenir de la Malmaison type. Many large plants of the Princess of Wales and the old Blush varieties were noticed. Some were in 10-inch pots, and many in 6-inch pots for supplying cut blooms. In the plant houses were many Orchids,

ionantha in the stove, with much larger and brighter-coloured flowers than the type. It has been named after Mrs. Thos. Fielden. The variety is an acquisition. Poinsettias are given especial attention, and a large quantity of these winter-flowering plants are cultivated at Grimston Park. They were in fine condition in all stages, some being old plants that had been saved from previous seasons. These are cut down almost to the ground level, and give excellent results. No account of these gardens would be complete without reference to Mr. H. J. Clayton, who for many years had the care of these gardens and grounds. His good work can be seen on every hand, and is being continued by his successor, Mr. G. P. Bound, whose work shows evidence of a skilful cultivator. Since Mr. Clayton's

flower as a young plant, but only after reaching a certain age. The flowers appear, together with the young leaves, on the top of the branches. Calyx, pedicels, and the young shoots and leaves, are all densely covered with fine brown hairs which soon disappear from the upper side of the leaves and from the branches as they grow older. The branches are armed throughout from the youngest to the oldest with short, stout thorns, and possess a greyish-green smooth bark. The leaves are trifoliate, the side leaflets ovate-acuminate and truncate at the base, the terminal ones of the same shape and scarcely longer. They are not equally deciduous throughout the tree—some always remaining from one year to the other. The flowers are borne in dense but short racemes, which are all bent upwards, and

FIG. 27.—THE "EMPEROR'S WALK" AT GRIMSTON PARK.

including Cattleyas and Cypripediums in quantity, these being grown for their useful flowers in winter; also Odontoglossums, Dendrobiums, Lycastes, and other Orchids. A stove was filled with the usual array of heat-loving plants, and suspended from the roof were large baskets of Stenotaphrum americanum of the variegated variety, which are hung in summer-time from the rafters of the conservatory. This makes a fine basket plant, and affords a change from the species of Asparagus so largely used as trailing plants. A house planted with varieties of Begonia's Rex amongst rockwork, with Ferns, was very pleasing. In this structure were also large plants of Cypripedium insigne, growing amongst the stones. We noticed a variety of Saintpaulia

in the village of Ulsekelf.

NOTES FROM LA MORTOLA.

ERYTHRINA INSIGNIS TOD.

A PLANT of striking beauty when in flower, as it was in the middle of May, is Erythrina insignis. It is a large bush or tree, about 15 metres high, with very stout and thick divergent branches from the base, and certainly not often met with along the Riviera. It was described by Todaro from a large specimen in the Botanic Garden at Palermo, from which our plant may possibly have originated. It does not

are about 6 to 8 centimetres long; and sometimes are borne in groups of three at the top of a branch. The pedicels are 10 millimetres long, the calyx about twice as long, but rusty brown. The vexillum is the largest and the only coloured petal of the flower; it is of a most vivid fiery-red. It is elliptical in outline, but folded and strongly recurved, somewhat darker outside and paler inside at the base. It measures about 6 centimetres in length and 3½ to 4 centimetres in breadth. The carinal petals are much shorter, about 2½ centimetres long, of a pale insignificant green. The alae or wings are bent over them and are nearly as much coloured as the vexillum, but have a blackish-brown margin. The

stamens are long, exerted, and bent upwards in the same way as the vexillum. The filaments are of a dull green, and nine of them united to three-quarters of their whole length, which is 4 to 5 centimetres; the tenth stamen is free or nearly so. The anthers are small and brownish. The ovary is long, stipitate, and is surrounded by the staminal tube; it ends in a long, curved style, which finally bends in various ways. The flowers secrete a large quantity of sweet, watery juice, which doubtless serves in its native country to attract animals, most probably humming birds. Here a few pods are sometimes produced, perhaps in consequence of fertilisation by means of large bees. The native country of this tree is unknown. Todaro gives no origin. According to him the plant has been grown in the Palermo Botanic Garden for a long time (de tempo antico), but was received from the Royal Gardens at Bocca di falco. Our plant agrees in all details with Todaro's description and figure in his *Hort. Botan. Panormitanus* 6, t. ii. *Alcaen Berger, La Mortola, Italy.*

PLANT NOTES.

A NEW RACE OF FUCHSIAS.

It is doubtful whether *Fuchsia triphylla*, which was discovered on the Island of Hayti or St. Domingo over a couple of centuries ago, was ever in cultivation in this country till within recent times. At all events, its introduction, or perhaps reintroduction, in the early eighties by Messrs. Henderson, of St. John's Wood, attracted much attention, and owing to its distinct appearance and the vivid colour of the blossoms, great anticipations of its possible value to the hybridist were indulged in.

Many attempts at crossing, however, only ended in failure, and several years elapsed before a pretty hybrid of German origin was put on the market. This, known as *F. triphylla hybrida*, was the result of crossing *F. triphylla* with *F. corymbiflora*. Two or three other seedlings which much resembled the first hybrid were also put into commerce, but no decided break was met with.

Within the past few years, however, matters have changed, and the German nurserymen have distributed several varieties showing a marked change from those previously grown. Judging by their general appearance I should say they are the result of crossing and intercrossing *F. triphylla*, *F. corymbiflora*, and *F. fulgens*. One of this section, viz., *Coralle*, was given an Award of Merit by the Royal Horticultural Society on September 3 of last year. A very attractive group, consisting of several varieties of these hybrid Fuchsias, was seen at the recent Holland Park Show.

The florists' varieties of *Fuchsia* have long followed the same line, so that a fresh break will be gladly welcomed. Among the best of these new Fuchsias are *H. Henkel*, with flowers a shade of reddish-salmon; *Coralle*, apricot, with a coral-red shade; *Perle*, pale yellowish-salmon with a pink shade; and *Gartenmeister Bonstedt*, rosy-red shaded salmon, while the young leaves are of a bronzy hue. An older variety, *Mary*, more nearly approaches the typical *F. triphylla*, the blossoms being bright crimson in colour.

In addition to these, one could not fail to notice at Holland Park the many delightful hardy Fuchsias exhibited by Messrs. Jas. Veitch & Sons, Ltd. There is undoubtedly a great future before these plants, but the surprising part of the matter is that several of the best were raised and distributed many years ago by M. Lecomte, of Nancy, without their merits being generally recognised. Should they now attain the position in gardens that they are entitled to, these Fuchsias will furnish another illustration of plants ignored for a time becoming ultimately popular. H.

The Week's Work.

FRUITS UNDER GLASS.

By T. COOMBE, Gardener to Lord LEANINGTON, The Hendrie, Monmouthshire.

Tomatos for fruiting in winter.—Plants that were raised from seeds sown thinly in pans or shallow boxes early in July, and placed in a cool frame, should as soon as they develop rough leaves be potted singly into small pots. Slightly shade the plants from the sun until they have recovered from the root disturbance, and afterwards expose them to the weather at all times when the conditions are favourable. When well rooted repot them rather firmly into 6-in pots, using a compost of loam, lightened with broken manure from a spent Mushroom bed, and wood ashes. Place the plants in an unheated frame and remove the lights except during bad weather. If frames are not available, place the plants in rows in a sheltered position in the open; secure them to stakes, and screen their pots from the sunshine by placing against them some thin boards on edge. Take proper care in watering and do not afford manure water. *Sunrise* and *Frogmore* Selected are good varieties for winter fruiting.

Tomatos in fruit.—Plants that were put out as successional crops to forced Strawberries have now their earliest fruits swelling freely, and should be top-dressed with a compost enriched with bonemeal or some similar fertiliser. They may also have occasional waterings with diluted drainings from the farmyard. Keep the leading growths secured to the trellis, or stakes as the case may be, and stop the lateral growths closely. Ventilate the house freely and keep a tolerably dry atmosphere. Should white fly be troublesome, either fumigate or vaporise the house. Maintain a fairly dry air by night, and ventilate freely early in the day in order to prevent moisture from condensing upon the ripening fruits, otherwise mis-chief may result from sun scalding. Fungus diseases are not likely to appear if the structure is kept properly ventilated, the atmosphere fairly dry, and the temperature reasonably warm, but should the fruits become affected spray both the plants and their surroundings either with a solution of sulphide of potassium—1 ounce of sulphide in a quart of hot water, with enough water added to make 2½ gallons—or with the Bordeaux mixture.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WINTAGE, Lockinge Park, Berkshire.

Lilium candidum.—This species is one of the handsomest of all the Lilies. Soon after the plants have finished flowering the bulbs should be lifted and stored for a period of about two months. But they should first be dried by exposure to the sun. When planting these bulbs they should be placed on a layer of sand, and not covered deeply with soil. It will be noticed that shallow-planted bulbs, even though they may be quite green, always give the best flowers and are the most healthy. One often sees these Lilies doing splendidly in cottage gardens, the reason being that they are not often interfered with. An over-rich and moisture-laden soil is especially harmful to the *Madonna Lily*, and is a frequent cause of the plants being diseased. As a precaution against disease, dust the bulbs and the soil in which they are planted with sulphur.

Hedysara sanguinea.—This handsome perennial plant flowers from early summer to autumn. Now is a suitable time to sow seeds or to propagate the plant by cuttings or by division of the root-stock. It will grow in almost any part of the garden and in any kind of soil, but it needs to be frequently replanted, as the crowns when large raise themselves considerably above the ground level, and from this cause are often injured by frost.

Viola cuttings.—Shoots of the *Viola* root readily in a cold frame partially shaded from direct sunshine. The use of a frame is necessary if they are intended for planting at the end of October or early December, but if they are not required until the spring they may be inserted in the open, selecting a sheltered, shaded position for the purpose. When inserting the cuttings allow plenty of space between them so that each may be lifted with a good ball of soil

at the roots. Among the best varieties of *Violas* for bedding purposes are *Lord Elcho*, *Duchess of Sutherland*, *Countess of Hopetoun*, *Countess of Kintore*, and *Archibald Grant*.

Isatis glauca.—This is a very handsome border plant flowering at this season of the year, the small, clear yellow flowers being borne in immense numbers. The plant grows about 4 feet in height, having light green stems and glaucous foliage. The inflorescences form spreading panicles, and though the individual flowers are small the effect produced by the sprays of bloom is very fine. The plant is quite hardy, and being a perennial may be increased by division. It may also be raised from seeds.

THE APIARY.

By CHLOEIS.

Bees and the Heather.—It is useless to attempt to remove to Heather-covered ground some distance away any hives containing combs not swayed for there is little doubt but that the vibration of a wagon or a railway truck would cause them to break down. Further, it is useless to take any colony that is not bubbling over with bees. Often it pays to unite colonies that are to be utilised on the moors, so as to make them extra strong. Having made up our minds what kind of colony will repay us for our trouble, the next is to make the hive secure for travelling. The frames must be tightly wedged, a piece of perforated zinc must take the place of the gable and two laths laid on the top of the zinc across the frames, and tightly secured down to prevent them swinging. The entrances must be made secure by screwing on perforated zinc, and then the whole hive tightly roped together. If any accident should happen and the bees are liberated, thus causing damage to anyone, the apiarist is responsible. Knowing this, one cannot exercise too much care in making all quite safe. If a cart or wagon be utilised to remove the bees, allow the hives to rest on a good bed of straw to prevent any unnecessary jar. Let the whole operation be performed at night. Generally speaking, sections are best for the purpose, because Heather honey is so dense that an extractor will fail to throw it out, and so it must be pressed out, which means the loss of many valuable frames of drawn-out comb for the next season. When sections are utilised, if the foundation is drawn out, so much the better. The crates must be very snugly wrapped up to prevent any draught from entering; pack in as much as you can around them, and place good warm quilts, with brown paper between them.

Supers.—If we keep the supply of space a little in advance of the bees' requirements we may prevent swarming. When frames or sections are all filled, save those on the outside, then another crate may be added. By adding too rapidly and giving too much space we defeat our purpose and disappoint the bees. Much uproar may be caused in an apiary by performing the task, either clumsily or at an improper time. Choose a bright day, not a cloudy one when the bees are having a slack time, as they are then less likely to sting. The new super must be placed underneath the one that is nearly completed. Have the crate near at hand and the smoker well charged and also well lighted. Give the bees a little puff of smoke at the entrance and wait two or three minutes, so that they may gorge themselves with honey, which robs them of the desire to sting. Remove the roof, and as you turn back the quilt puff in a little smoke between the frames or sections. Then lift the super by giving it a slight twisting and upward movement. With the new smoker drive the bees down the queen-excluder zinc, and add the new crate, replace that or those removed above, and wrap up warmly as advised before; fit the roof securely to prevent intruders gaining access to the hive, as otherwise robbing is very liable to occur.

Robbing and its cause.—Robbing is often caused by leaving about pieces of comb containing honey, for bees seem to derive much pleasure from gaining honey easily. Fighting on the alighting board is the danger signal to the beekeeper. Later in the season when feeding with syrup robbing is often seen, but this may be prevented by spilling the syrup in the neighbourhood of the hives and by closing the entrances so that one bee only may enter at a time.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. G. L. HOLFORD, C.V.O., C.I.E., Weston-on-Trent, Gloucestershire.

Oncidium (continued).—Among the cooler-growing species are some of the most showy kinds, and many of these are extremely useful plants to cultivate for making a display in late summer and autumn. *O. varicosum* Rogersii is perhaps the most extensively cultivated of these species, large consignments of plants being imported annually and sold at low prices. The great demand is due to the fact that there is no flower which is more valuable for exhibition or decorative purposes than the long, handsome spikes of this yellow *Oncidium*, either as seen on the plant or in a cut state. Other handsome and attractive kinds are those members of the *O. crispum* group, such as *Rosea*, *Garberi*, *O. crispum* and *O. Martini*; also *O. tigrinum* and *O. dasystyle*, &c. Examples of these that are well established and growing freely are best given a position close up to the roof ventilators in a cool, intermediate temperature, where they may enjoy the full benefit of the light and air, which is so essential to the maturation of the pseudo-bulbs and the subsequent producing of strong flower-spikes. At this stage a plentiful supply of water at the roots is needed, and, weather permitting, the plants should be freely syringed overhead until the present season's growth is practically completed. *O. olivaceum*, *O. microchilum*, *O. Phalanopsis*, and others that have flowered during late spring and early summer will now be commencing their season's growth, and as the latter advance the supply of water at the roots should be gradually increased. These plants should be carefully examined, and, if necessary, the work of re-potting or top-dressing should be carried out at once, according to the remarks described in a former Calendar. These remarks apply also to that magnificent species, *O. Marshallianum*, and the beautiful, compact-growing species, *O. concolor*. These flower in spring and early summer, and they thrive in a cooler atmosphere than any of the others already mentioned. *O. flexuosum* is a very common Orchid, but one of the most useful and beautiful kinds in cultivation. For cutting purposes there is hardly another to compare with the flowers of this species, as the spikes, owing to their light, graceful appearance, can hardly be regarded as such. This species is usually grown in too cool an atmosphere and close a compost for it to yield the best results. I have seen plants growing in a shady part of the Cattleya house in Sphagnum-moss and charcoal alone, making wonderful growths, the spikes being very long and exceedingly numerous. During the growing season these plants require an abundant supply of moisture at the roots.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STURLING, Esq., Keir, Fife-shire, N.E.

Primula sinensis.—Plants that were potted in 3 or 4-inch pots are now ready for shifting into receptacles having a diameter of 6 inches, for this *Primula* must never be allowed to become root-bound in small pots. A suitable compost is loam and leaf-soil in equal proportions, with a sprinkling of sand and some old Mushroom bed manure, but the latter may be replaced by a little Peruvian guano. In potted plants the plant just deep enough to allow a slight covering of soil over the old ball; make the soil moderately firm in the pots. Newly-potted plants should be watered very carefully for some time after re-potting; rather err on the side of under-watering than giving too much. The pots should be placed on a bed of ashes in an unheated frame where they must be shaded from bright sunshine, but, of course, the shading must be removed when the sky is overcast. Ventilate the frames early in the morning, to prevent the plants from becoming drawn, and weakly in growth, and for the same reasons allow plenty of room between each plant, each of which should be turned half-way round once a week. Pinch off all the flower-spikes as they appear in order that the plants may not expend their energy in this direction. *Primula obconica* and *P. sinensis*, but in their case the pots should be plunged in ashes.

Cinerarias.—Plants that were pricked out into boxes last month are now ready for potting into 4-inch pots. Use a similar compost to that advised above, but use rather more loam and add a sprinkling of bone-meal. Keep the ashes in the frame well damped during hot weather and remove the lights at night time when circumstances permit.

Mignonette.—Pot plants intended for autumn and winter flowering are now making rapid growth, and should be placed at the back of a wall having a northern aspect, but, although they need shade from direct sunshine, they must be given conditions that will encourage plenty of leaf growth but not flowers. These latter should be pinched as soon as they appear and the shoots be trained by means of very small stakes. Guard against caterpillars, which do much harm to the foliage. Springe the plants daily during bright weather, placing a little soot in the water. As the root system is now well developed, weak liquid manure should be given about twice a week. Batches of later plants should be re-potted in a compost consisting of loam two parts, leaf-soil one part, sand and old lime rubble one part, with some old Mushroom bed dung. The pots should be provided with plenty of drainage material, as Mignonette requires an abundance of water, but it must not be allowed to remain about the roots, and it would be liable to do this if there was not good drainage, as the soil needs to be pressed moderately firm when potting.

Freesia refracta alba.—The bulbs of old plants that were forced last year, and which have been given a suitable period of rest, should have the old soil shaken from them and the largest bulbs be potted into 6-inch pots, in loam, leaf-soil, and sand. Manure is not needed, for feeding can be practised after the plants have started into growth, but it is essential that the rooting compost be of an open texture. When they are potted stand them on a bed of ashes, and place a layer of ashes or sand on the top of the pots until the shoots begin to push through, when they should be at once placed close to the glass in an unheated frame and allowed plenty of ventilation.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to THE DOWAGE LADY, NARBOROUGH, Warton Priory, Yorkshire.

Budding.—When the branches of fruit trees have become bare from any cause, the bare places can be easily refurbished with shoots by inserting buds on the old branches where it is most desirable to have them. If hot, dry weather prevails after this operation, it is advisable to syringe and shade the branches from the bright sunshine. Peach, Nectarine, Cherry, and Plum trees may all be budded at the end of July and the beginning of August; if the work is done carefully during dull weather, success is almost certain. The process of budding fruit trees is exactly similar to that for Roses. Select plump buds from half-ripened wood, remove any wood that is present with the handle of the budding knife, and make an incision about an inch long in the stock with a cross cut at the top, in the shape of a T. Insert the bud by carefully and delicately pushing it down with raffia, but not too tightly, it only being necessary to exclude the air and the wet. The buds will remain dormant during the winter months, but in the following spring they will burst into growth.

Newly-grafted trees should be given attention, and if the scions are thoroughly united to the stock and growing freely, the binding material may be removed entirely. Young shoots on dwarf stocks should be properly secured to a neat stake to prevent the new shoots being damaged by strong winds. This also applies to grafted standard and other trees. Remove any suckers or shoots that appear below the graft.

Prickets.—The fruits are now swelling fast, and it should be ascertained that none is being injured between the shoots and the walls or against the nails. Where the foliage is dense about the fruits, remove a few of the leaves, but not so as to fully expose the fruits, as these ripen better and are finer generally when shaded with a little foliage. Keep a sharp look-out for woodlice, as these pests often damage the best fruits. Syringe the foliage two or three

times a week before the fruits ripen, in order to keep down insect pests.

Thinning fruits.—The rains which have fallen during the past week will assist in swelling the fruits and in cleansing the trees from insects. Apple and Pear trees, which are bearing heavily should be thinned of all unnecessary fruits, for over-cropping not only spoils the size and quality of the fruits but also militates against a reasonable crop the following year. Care must be taken when thinning the fruits to study the character of the individual variety, for in the case of a small-fruited kind a larger number may be allowed to develop than should be permitted with larger varieties.

THE KITCHEN GARDEN.

By E. BICMART, Gardener to the Hon. Vicars Gibbs, Aldenham House, Ebsay, Hertfordshire.

The Cabbage.—Preparations should now be made for sowing the principal batch of spring Cabbage. This is such an important crop that special care should be taken to ensure good results. Complaints are made each year that a large percentage of Cabbages flower prematurely. This is owing chiefly to sowing the seeds too early and selecting bad stocks. If the seed is not sown before the end of July, and reliable varieties only chosen, growers would not experience much trouble in this respect. Select an open quarter of ground which has not been lately manured, fork it up, and then rake the surface to a fine tilth. Scatter the seed thinly broadcast, and protect it from birds by nets. A second sowing should be made about the end of the first week in August. Three excellent varieties are Ellam's Early (still unsurpassed as a spring Cabbage), Sutton's April, and Flower of Spring. The last-named is a larger Cabbage than either of the other two, and is ready for use about a fortnight later. These three sorts only are grown they will afford all that is required either for a large or a small garden in the way of spring Cabbages. Red or pickling Cabbage should be sown at the same time as the second batch of spring Cabbage.

Caldworts.—There are few more useful vegetables for autumn and early winter use than these, consequently large breadths should be planted on ground which has been liberally manured and deeply worked. Plant them 12 inches apart each way, and make two or three plantings at least, to allow for a succession.

Winter Greens.—The showery weather has been ideal for getting these planted and established. Any which have been placed between the rows of Potatoes will need exposing to the light and air by bending down the haulm of the Potatoes about them. Savoys, Broccoli, and Kales may still be largely planted on any available ground. These late plantings frequently endure a severe winter much more satisfactorily than earlier plants. It is a good plan to start very late Savoys on a south border which has been well manured.

Brussels Sprouts.—Strong, established plants should be well earthed up, and the soil made very firm about them to prevent the wind blowing them about; when several sprouts are required, the plants should be secured to stakes.

Synanth.—This vegetable may now be sown in large quantities on well-prepared ground. The Carter is an excellent variety for sowing during the next fortnight, but it should be thinned to a good distance apart just before the second leaf is made; a distance of 6 inches will be none too great. Fresh soot should be liberally strewn over the young plants, especially during showery weather.

Celery.—Seldom have I known the Celery fly to be more troublesome than it has been this year, and only by constant hand-picking and frequent applications of soot has the crop been able to make any headway. I believe this trouble has been universal, but it may cause more worry for this is now over; but may cause annoyance again in the autumn. Continue to blanch the earlier plantings which may be required for consumption next month and early in September, the most simple and effectual way being to place bands of brown paper about 6 inches in width, around each plant at a height of about seven or eight days until the desired height is reached. When doing this, place a little soot around the base of each plant.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens or plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY of the paper, and as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unsold communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, JULY 23—
Bishop's Walkham Fl. Sh. Midland Counties Sweet Pea Soc. Exh. at Wolverhampton, Chesterfield Fl. Sh.

THURSDAY, JULY 30—
Royal Lancashire Agric. Soc. Sh. a Manchester (4 days)

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich—63° F.

LOCAL TEMPERATURES—
LONDON.—Thursday, July 22 (6 P.M.): Max. 77°. Min. 56°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, July 22 (10 A.M.): Bar. 30.1; Temp. 72°; Weather: Bright sunshine.

PROVINCES.—Edinburgh, July 22 (6 P.M.): Max. 73°. Guildford: Min. 58°. Bristol.

We have no hesitation in characterising the *Types of Floral Mechanism** as one of the most remarkable of the books dealing with flowering plants that has appeared within recent times. The volume before us forms the first instalment only of the entire work, but it is to be hoped that the appearance of the other volumes may not be long delayed.

We had gathered from the introduction that the treatise was intended for the "elementary student," but we confess we should like to meet that student. Even Macaulay's omniscient schoolboy would prove the veriest dunce beside him. Doubtless there is a great deal in the work that may be utilised for elementary instruction, and this is further helped out by the magnificent series of illustrations which the book contains. But much of the subject matter is such as can only appeal to the very advanced student, though to him it will assuredly prove very stimulating.

The general plan of the work has been to take individual flowers as representative types, and around them to group the related forms, thus exhibiting the flexibility of the type and the play of variation around it. Twelve such plants, which are in flower from January to April, are selected for treatment in the present volume, which we presume is to be followed by at least three similar ones. A short historical account of each of the principal plants described is given, its economic uses, distribution, and other facts of general interest are added. Then follows a morphological account of its structure, accompanied by admirable explanatory figures, some of

* A selection of diagrams and descriptions of common flowers arranged as an introduction to the systematic study of Angiosperms. By Arthur Harvey Church, M.A., D.Sc., Part I., Types I-XII, (January 1907). Oxford: Clarendon Press, 1908.

them in colours. Details of pollination, the structure and development of the fruit and seed are presented in full, and the more general aspects of the matters raised in connection with a particular plant are dealt with under "Theoretical Conclusions," and the latter will be found well worth reading by the most advanced botanist. The whole treatment of the subject is remarkably original, and constantly challenges the reader by the provocative—we had almost said dogmatic—way in which new views are set forth. Every page of the book is full of matter for thought, and while no doubt many will refuse to follow the author in all his conclusions, all must admit the stimulating influence of the ideas enunciated.

Dr. Church very skillfully works up his conception of the "Mean Type" towards which so many decotyledonous flowers approximate, and he urges the importance of distinguishing similarities due to mere convergence from marks of real affinity. He also traces in a very interesting way that peculiar and often recurring type of floral organisation, illustrated by Ribes, wherein the outer floral whorls become raised up by the intercalation of what is termed the "zona perigyna."

Naturally, in a work of this kind differences of opinion will obtain respecting some of the positions adopted by the author. We ourselves demur to the term racemose being applied to inflorescences in which the terminal flower opens first, for such "racemes" seem to us to have originated from cymose types. They are specially abundant in forms whose near allies exhibit the cyme in its most typical form. To term them racemes seems to confuse convergent series with related ones, a confusion against which, in another connection, Dr. Church especially warns his readers.

Again we feel compelled to take exception to "gynœcium," which is used instead of the more usual (and correct) rendering gynoecium.

Many people, it is to be hoped, will appreciate the statement, on page 99, respecting cleistogamous flowers and their origin. "There is no reason to regard the production of cleistogamic flowers as at all an act of compensation for a lack of normal fruits, owing to failure of the mechanism of cross-pollination." The breezy way of putting forward this unquestionably correct statement may perhaps shock some of those naturalists who are really Lamarckians at heart, but we believe it to represent a perfectly accurate statement of a plain fact. Dr. Church mentions the interesting circumstance that Violets which have been forced, are prone to exhibit premature germination of the pollen whilst still within the anther, and he suggests that this may afford the clue to a correct explanation as to how cleistogamy became a possibility.

We cannot conclude a notice of this important work without congratulating the author and the publishers alike on its production. The Delegates of the Clarendon Press have already deserved well of botanists for the sake of the well-known series of translations which have been issued from Oxford, and this new undertaking is well worthy of the best traditions of the Press.

It is, in the best sense of the word, a scholarly scientific work that deserves to be widely known and generally used.

OUR SUPPLEMENTARY ILLUSTRATION.—For the opportunity of illustrating the new single yellow Paeony known as *Paeonia Mlokosewitschii* we are indebted to Mr. W. E. GUMBLETON, of Belgrove, Queenstown, who also supplied us with the material from which the illustration of the Paeony figured last week was prepared. *P. Mlokosewitschii* is described in the *Botanical Magazine* as belonging to a group of yellow-flowered Paeonies from the Caucasus, the others being *P. Wittmanniana* and *P. macrophylla*, all of which are very closely allied, and may possibly be merely forms of *P. corallina*. The species we now figure was discovered by MLOKOSEWITSCH near Lagodeckhi, in the eastern part of the Central Caucasus, whilst typical *P. Wittmanniana* is a native of Adsharia, in the basin of the Tshorok River, south of Batum. Mr. GUMBLETON obtained his plant from Mr. MAX LECHLIN, of Baden-Baden, and since that time young plants have been raised at Kew from seeds received from the Tiliis Botanic Garden. Mr. W. WATSON, also writing in the *Botanical Magazine*, describes this species as the most handsome of the yellow-flowered Paeonies, but Mr. GUMBLETON informs us that the colour of the flowers is not nearly so rich a shade as shown in the *Botanical Magazine* figure (tab. 8173). Mr. WATSON further states that the plant thrives under the treatment suitable for the other forms of herbaceous Paeonies. The glaucous leaves with their red veins and markings have a good effect, independent of the flowers.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual outing will, this year, take place on Monday, July 27, when a visit will be paid to the Royal Gardens at Frogmore. The party will travel to Windsor Station, and proceed to the gardens. Lunch will be served at Layton's Restaurant at 1.30 p.m. After lunch there will be time for a short visit to St. George's Chapel, and at 3.30 p.m. the party will embark at Windsor Bridge for a trip up the river. A halt will be made at Maidenhead for tea (about 5.30), and after tea the party will return so as to reach Windsor in time to catch the 8.28 p.m. train to Paddington.

HORTICULTURAL COLLEGE, SWANLEY.—Lady BECTIVE distributed the prizes awarded the lady students of the Horticultural College at Swanley on July 14, in the presence of an influential assembly of the supporters of the institution, which is a pioneer one of its kind in the country. Sir JOHN COCKBURN presided. Lady BECTIVE spoke of the new field that was opened out to women in regard to horticulture. They loved their gardens, but had been unable in the past to accomplish much in them from lack of knowledge. She was delighted with the work being done for women in association with the college, and she was also pleased to learn that the students had done so well in their work and examinations. Lady BECTIVE also remarked, says the *Times*, that she was gratified beyond measure to learn from Sir JOHN COCKBURN of the great success of the colonial branch of the college's work, and that the college had been recognised by the Government as one of the first institutions for third year training in horticultural and nature study for those teachers who were taking up these subjects.

ROYAL VISIT TO CHESTER AND STOCKPORT.—In connection with the recent visit of their Royal Highnesses the Prince and Princess of WALES to Chester and Stockport, the whole of the floral decorations at Chester Town Hall, Northgate Railway Station, Chester, and Tiviot Dale Railway Station, Stockport, were carried out by Messrs. DICKSONS, LTD., Chester, under the supervision of Mr. J. SMITH, chief of their floral department. The decorations were much admired by the royal visitors and general public

THE MIDLAND CARNATION AND PICOTEE SOCIETY'S show will be held at the Edgbaston Botanical Gardens, Birmingham, on August 6 and 7. In addition to Carnations and Picotees, special classes are provided for Sweet Peas. Particulars may be obtained from Mr. T. HUMPHREYS, Botanical Gardens, Birmingham.

AMERICAN GOOSEBERRY-MILDEW.—It is stated that there are at present several severe cases of American Gooseberry-mildew on Gooseberry bushes in commercial gardens in Kent.

THE ROYAL VISIT TO LEEDS.—Our Leeds correspondent writes as follows: The visit made by their Majesties the KING and QUEEN to Leeds on July 7 was the first visit of a reigning sovereign to this town for some hundreds of years. The decorations carried out in honour of the event were remarkably good. It was surprising how all the plants, cut flowers, and foliage had been got together. The embellishment of the Town Hall called forth the best efforts. When it is said that both his Majesty the KING and his royal consort freely gave ex-

also tastefully decorated with large Palms and flowering plants, similar groups being suitably placed along the sides of the roof. Along the corridors leading therefrom to the luncheon room were dados, some 4 feet in height, of diamond trellising stained a light mahogany and thinly furnished with Ivy and other suitable plants. Every few yards were arches of evergreens, &c., with branches of the Dog Rose in flower twined in them. As will be seen, these dados formed an excellent means of carrying the eyes along from arch to arch. The main façade of the Town Hall presented a grand massive appearance; hence it required much thought in temporary decorations. The scheme was a great success, though it would be difficult to describe here. The parks superintendent, Mr. A. J. ALLSOP, was responsible for the whole.

THE LATE MR. ARTHUR LISTER, F.R.S.—It is with great regret that we learn of the death, on Sunday last, of Mr. ARTHUR LISTER, F.R.S., the well-known authority on the Myxomycetes or Slime Fungi. His monograph on these plants,

covered with wire gauze not coarser than 15 wires to the inch both ways; all pools, ponds, fountains, or other water receptacles not containing fish to be screened as above, or covered with crude petroleum; forbidding any water to remain in any receptacle whatsoever; requiring all privy walls to be thoroughly covered with kerosene every 15 days; and that water be turned off, and water receptacles emptied should a house be unoccupied for more than five days. The penalty for neglecting to comply with any of these requirements was a fine not exceeding \$2 per day. Dr. C. M. HILL, who had charge of the work, brought the matter more forcibly before the public by delivering a series of lectures explaining the mode of mosquito extermination, and cards were displayed in the tramcars calling the attention of householders to the importance of their co-operation in the work. Reporting upon the experiment (Annual Series, No. 3,982) Mr. CONSUL FRASER says the result of it is satisfactory, and the City Council has appropriated another £1,000 for continuance of the work in 1908. Dr. HILL is grateful to Dr. ROSS, of the Liverpool School of Tropical Diseases, for much valued advice in his efforts to exterminate the mosquito, which has hitherto been the cause of so much illness and death in Baltimore. *Journal of the Society of Arts.*

M. LE TEXNIER.—This gentleman has been much occupied with the historical aspects of popular flowers. His publications include "The History of the Tulip," "The History of the Chrysanthemum," "The History of the Carnation," "The History of the Hyacinth," and "Notices on Celebrated Gardeners and Garden Amateurs." They are neat little booklets of 30 or 40 pages each, and contain many historical and literary details that amateurs of these flowers will highly appreciate. Some are published by the Librairie Horticole, Paris; others by the Imprimerie Montparnasse.

SAXIFRAGA VANDELLII.

This scarce species (see fig. 28) belongs to a small section of the genus of which *S. Burseriana* is the best-known example. It is somewhat similar in habit to *S. Burseriana*, having closely-matted stems that are densely clothed with stiff, three-edged, sharply-pointed leaves. In flowering it is later, for its blossoms do not open till early in April, when most of the different forms of *S. Burseriana* are over. The illustration at fig. 28 shows the species flowering in a pan in the Alpine house at Kew during the early weeks in April. The plant had been grown in a cold frame, the pan being plunged to the rim in ashes. As a rock-garden subject, it does not grow and flower so freely as when cultivated in a frame, where it receives protection during bad weather. In the open it needs to be wedged between stones, and in such a position that its roots are readily within reach of moisture.

S. Vandellii is found on the Alps of the Tyrol and north-eastern Italy, where it grows on calcareous rocks, and forms dense tufts of foliage. The flowering stems are densely villous and glandular, about 2 inches high, and bear from five to ten flowers in a cyme. The flowers are of a good size, ivory white, save that the oval petals have five straight nerves. Although the plant has been in cultivation for a long time, it is not frequently met with in gardens, owing probably to the difficulty of establishing it. The rooting medium should consist of a very gritty soil, composed near the surface of nearly all stones, between which the plants should be tightly wedged. The plant forms a useful subject as a succession to *S. Burseriana*, and is well worth growing in a cold frame. *W. Z.*

FIG. 28.—SAXIFRAGA VANDELLII, FLOWERS WHITE.

pression to their great pleasure and satisfaction, no more need be said. It was in connection with the rooms set apart for the royal luncheon and the retiring rooms of their Majesties that the most artistic floral decorations were to be seen. These rooms open from a corridor some thirty yards in length, the whole of which was made into a rustic archway or pergola, young Birch trees being mainly used for the purpose. These were most tastefully covered with "Dorothy Perkins" Rose full of flowers, which seemed to grow up naturally from a narrow border of dwarf flowering and foliage plants on each side of the corridor. Amongst these were batches of Lily of the Valley, Liliiums in variety, Gladioli, and Pelargoniums, the whole being edged with a natural-looking dwarf green Sedum. To complete the picture, a rustic gate made from peeled Oak branches was fixed at the end first entered. Large flowering plants of the same Rose were placed in the royal rooms, cut branches being also used for the decoration of the luncheon table. The royal dais in the Victoria Hall was

published as a British Museum catalogue, is the finest work on the group in existence, and is copiously illustrated with excellent plates, many of which were executed by his daughter. A second edition of this important work is in course of preparation, and every botanist cannot but feel the deepest regret that the author has not been spared to see its completion. Mr LISTER, like many other eminent botanists, belonged to the Society of Friends, and his remains will be interred in the grounds of the Friends' Meeting House at Leytonstone.

THE EXTERMINATION OF MOSQUITOES.—The people of Baltimore seem to have been successful in their warfare with the mosquito. In December, 1906, an ordinance was passed by the City Council, and the sum of £2,000 appropriated by it for the purpose of taking measures to exterminate the insect. In the following May the work began, and the first step taken was a distribution by the police to householders of a notice setting forth the provisions of the law requiring all the cisterns, tanks, and wells to be

* THE FRENCH SYSTEM OF MARKET GARDENING.

(Continued from page 47.)

I HAVE only at present mentioned Cabbage Lettuce, but I know of a very good price can be got for Cos Lettuce, which are, if anything, more easily grown than the Cabbage Lettuce.

The market gardeners of Paris employ Romane or Early Clôche Cos for winter culture in the same manner as Early French Cabbage Lettuce. The seed of this Cos Lettuce is sown during the first days of October; its culture is almost the same as the Early French, but to prevent mistakes I repeat it here.

The first week in October one should prepare a well-sheltered place facing south; after digging, carefully rake the soil, and on the top put 2 inches of rich compost. Make the bed quite level, put on one corner of this a bell-glass and press firmly on the top, so that the rim of the glass will imprint a ring on the ground. Take it up, and place it at the side to make another ring, and so keep on. When there are enough rings marked, sow the seed thinly in each circle, and cover with half-an-inch of very fine soil, placing a bell-glass over each circle. One can also sow the seed at the end of an old hot-bed. The seed will come up in three or four days, and 12 or 15 days afterwards the plants ought to be pricked out under the bell glasses on a bed prepared in the same way as for sowing the seed. Prick out 24 to 25 plants under each bell-glass, and put on the bell-glass immediately. The plants will take root in a few days, and, as the Cos Lettuce likes the air, raise the bell-glasses a little during the day, but shut them down again at night. When severe weather comes, cover with mats and make a ring of manure round the bed where the bell-glasses are, and put very short and dry manure between the bell-glasses and double mats. When the cold has gone, take off the coverings and admit air if the weather permits. In January or February choose the strongest plants and plant one under each bell-glass, together with four early French Cabbage Lettuces.

The whole of the ground allotted to the Cos Lettuce should be sown with early Carrots. The Cos have room to develop, and after these latter are cut, take off the glasses and carefully thin out the Carrots if too thick. The first were forced in Paris in 1812.

On the outside the smaller-sized plants of Cos Lettuce are planted to be coming along, and as soon as those under the cloches are cut, the ones outside are ready to have the cloches moved on to them to get a second crop.

The British market gardener is a very conservative sort of fellow. What his father and grandfather did before him, he is quite willing to go on doing still, and he cannot understand why any "new-fangled" thing should come along. His forefathers have been quite content to grow Schoefelds and Lees' Immense Lettuce to come in in the spring, and so is he, and what were good enough in the old days should be good enough for his customers. There is no need to have these new-fangled Lettuces sent from Paris.

This is all very well, but the world goes on, and those who will not move with the times are eventually left behind in the race.

If English people in the districts suited for early culture would give this French system a trial, they would find that it would be to their benefit, but you must not think that this is a royal road to fortune. You will have the same ups and downs that you have had in ordinary gardening, but the results in the end are much better.

Here in our country we have an enormous population, and a well-to-do population, who can afford to buy from Paris these delicate early vegetables. They only want to be educated to the idea that they can obtain these in England, and that they can have them fresh on either their lunch or dinner table, at the same moment, instead of being stewed in boxes while coming from France, perhaps taking three or four days to do it, and possibly lying in a shop window two more days until they are sold.

I believe, indeed I am sure, that it is possible to make French gardens here, but I also know that it will entail very hard work.

A Frenchman for seven months works 18 hours out of the 24, and through the other five months he works 14 hours a day. You must not think he looks overworked; he does not, but is as happy, contented and jovial a man as you can come across.

A French market gardener does not get on well without a wife. If the husband cultivates the garden, the wife is the only one who can properly see to the produce being packed, sent away, and sold. They get up every day very early, breakfast at seven, lunch at ten, and have dinner at two o'clock.

The Frenchman has devoted his energies to the production of premeurs until it has become a science. He produces forced Asparagus in November, an abundance of Lettuce in January, Cos Lettuce in February and March, and Carrots, Radishes, and Strawberries in March, and Tomatos, Melons, &c., in April.

Market gardening is so much overdone in England that there is very little made out of it. It is a hand-to-mouth business, and where there is any possibility, which there is, of improving it by introducing some fresh style into the gardens, especially the small gardens which are in this neighbourhood, I am sure it would be an untold boon, because you would be taking more money at a time when you usually take very little. You can waste nothing on it because you have your frames, which are useful for other vegetables, and you have your manure, which is only partially exhausted when you have finished with it.

It may interest you to know how many of these frames, &c., are sent over to London every day during the season. The usual consignment of Lettuce per day is 4,000 to 5,000 crates, also 500 crates of small early Carrots, 500 crates Asparagus, 100 crates long French Turnips, and 50 crates Celeriac. Do not these figures give you some idea of the importance of this method of gardening?

At the present time, the price of Lettuces and Carrots very early in spring are prohibitive, except for those who are fairly well off for money, but if by production one can cheapen them so that they are within reach of everybody, the present quantity of 5,000 crates of Lettuce per day will speedily jump up to 20,000 crates.

These particular Lettuces are sold by the French gardener to a middleman at 6d. per dozen. The growers themselves do not ship anything to England, any more than you would send to retail customers, but they send their produce to a commission agent.

If the French gardeners get 6d. per dozen, they are quite happy; it pays them well, and I have seen no French gardens that do not look prosperous. Why should there be one foreign Carrot or Turnip or a single Lettuce brought into England, when all can be produced here? You will have no difficulty in getting 1s. or 1s. 6d. per dozen for Lettuce, even if they were what you considered to be low in price.

A great many of you will recollect the time when Tomatos were but very little grown, before they came into fashion. At that time they were sold in large price. When the Canary Islands and other places began to send in their early Tomatos, it was thought it would kill the English trade altogether. But has it?

I should say that at the present day there are 2 to 3 cwt. of Tomatos grown where one pound used to be grown years ago. They are one of the most paying crops there is, whether grown inside or out-of-doors.

Why should not this success be reflected in a partial way with these Lettuces and other produce?

Now as to the Cauliflowers, which our French friends grow, let me ask how many could be obtained in Cheltenham a month or six weeks ago? I am sure you could have gone all over Cheltenham and not obtained one, but how many could have been sold if you had had them?

I have brought a straw mat, which is used for this kind of gardening or any other if necessary, and should be used by all market gardeners here. It does not absorb the wet like an ordinary Arched mat, but allows the water to run off and they quickly dry. They are easily rolled up.

I have also been lent a frame on which these mats are made, as I should like to show you how easy it is to make them for yourselves.

The Paris market gardeners make all these mats themselves. There are several sizes and thicknesses, but the generality are neither too large nor too thick, so that they may not be too heavy, and that they may dry quickly after being wetted by rain.

In length they are 2 yards by 1 yard wide. They are used for covering bell-glasses and lights for keeping out the cold, and also for shading purposes. They are made as follows:—On a level floor, or on hard soil, fix two 1-inch boards 7 feet long by 1 inch deep, parallel at a distance of 4½ feet. The space between these two boards, which are for the purpose of fixing the width, is divided into five equal parts by four lines placed longitudinally 13 inches from each other and as long as the plants. At the two ends of each wooden line, a small wooden peg, the size of one's finger, is firmly placed in the ground, giving a space between the mat and the ground of 2 inches. These pegs determine the length the mat should be, just as the side planks determine the breadth. Then some tarred cord is attached securely to all the pegs at one end of the frame. Now, one has therefore five lines of tarred cord each 6 feet 6 inches long, but cord should not be cut the exact length from peg to peg. From experience, one has learnt that the proper thing is to double the cord, so as to have sufficient to secure the straw on to the cord stretched on the pegs. It is necessary to measure three times the length of the stretched cord, i.e., to make 6 yards before cutting the string. The loose end of the cord is wound on a bobbin of some description, so that it may be more easily handled.

On the string that is stretched, one puts clean Rye straw, and as long as possible, 1 inch deep, and so placed that the thick ends come outside against the planks, making the mat of equal thickness. Now one may go on with the sewing, if one may so call it. One or two people can sew at the same time. Let the workers kneel at the bottom of the frame where the bobbins are, and with the left hand take a bunch of straw about the size of a finger, and raise both it and the cord which is below. Then with the right hand pass the bobbin under the stretched cord and bring it back to the left hand. In this way they encircle a bunch of straw with string, which they tie tightly. Then take another bunch of straw and proceed as before.

When these mats are made at home they are very cheap indeed, but when they have to be imported from France they come somewhat dearer.

As you will see by my small book,* I advocate growing Strawberries under glass, not in greenhouses in the ordinary way, but in frames, the same as are used for this particular form of gardening.

In my book I made a special note on the packing of vegetables, in which I think we are backward; the French are much better than we are in this. I rather foolishly thought they did this for their own country as well as for abroad. Possibly they do, but I was eating Asparagus the other day at a French table, and saw that they, like our own market gardeners here, had placed the sprue in the middle.

BATTERSEA PARK.

In many of the flower-beds in this park the Fuchsia is freely employed, sometimes as an edging, but chiefly as standards, pyramids, and low bushes, with an undergrowth or carpet of some sort, and a bordering of plants of comparatively low growth. Fuchsia fulgens, an old inhabitant of gardens, but mostly treated as a greenhouse or conservatory plant, is here used in many parts of the park, and in various ways. This species appears to have been much employed as a parent in hybridising Fuchsias about 1837, when many varieties were raised between

* *The French Garden*, by C. D. McKay, price 6d.

it and other long tubular-flowered varieties, as *F. corymbiflora*, *F. cordifolia*, and *F. globosa*. Few of these early varieties are now to be found in gardens, excepting *Venus*, *Victrix*, *Venus de Medicis*, and *Goldfinch*. The first-named of these varieties was the first *Fuchsia* with a white tube and sepals introduced into gardens. *F. fulgens* makes a conspicuous bedding plant by reason of its red-tinted young leaves and the elegance of its vermilion-coloured, long, tubular flowers. It may be observed at Battersea in company with plants of *Erythrina Cristagalli*, *Anthericum variegatum*, and *Amaranthus melancholicus*, in lines in a sort of ribbon border, and mixed varieties of *Fuchsia*. There are mixed *Fuchsia* beds, consisting of tall bushes and standards, and between these plants of the variety *Display*.

A bed planted with tall plants of *Acer Negundo variegata*, having scarlet *Pelargoniums* beneath and a broad line of *Funkia Sieboldii* as an edging, had a good effect.

The plants of *Plumbago capensis* are making promise of a show of flowers finer than usual; but, on the contrary, *Cannas* are not making much progress. An unusual combination was noted in a bed in the sub-tropical garden. The plants employed were *Erigeron speciosus*, a pink-flowered *Pelargonium*, and a broad edging of the yellow-leaved *Lysimachia Nummularia aurea*.

Good use is made of Ivy-leaved *Pelargoniums* as pyramids, *Coleus* and *Lobelia* being employed as edging to some of these beds. *Salvia splendens* var. *Zurich*, mixed with *Heliotrope Madam de Bussy*, and *Iresine Lindenii*, had a pleasing effect.

Violas in all colours are much employed, and the plants are growing and flowering capitably. Some beds of *Roses*, *H.P.s.*, and others of *Tea* and *Hybrid Teas*, produced fine blooms until the recent storms occurred, spoiling them for a time. Turner's *Crimson Rambler Rose* has flowered abundantly; indeed, the *Roses* have done wonderfully in this park in the present season—an unusual occurrence in London.

Specimens of *Vitis Coccinea* and *V. flexuosa* have made ample shoots by the lake side; likewise *Polygonum Baldschuanicum*. The various borders, to the upkeep of which Mr. Rogers pays great attention, are gay with *Lillies* in variety, *Sweet and Everlasting Peas*, *Hollyhocks*, *Delpiniuns* (especially fine this year), and *Hemerocallis*, together with numerous herbaceous plants, that will come into bloom as the season advances. *F.*

TRADE NOTE.

GEORGE MOUNT & SONS, LTD.

THIS firm has been registered with a capital of £30,000 to acquire and carry on business as nurserymen, florists, flower and fruit growers, farmers and hop growers, at Canterbury, Folkestone, Herne Bay, and other places in Kent. It is a private company formed to enable George Mount to take his four sons into partnership, and no shares are offered to the public.

We are informed that Mr. George Mount first founded the business in 1884. He hired 3 acres of ground, being part of a 40-acre field at St. Dunstons, Canterbury, put up two glasshouses, and planted up most of the ground with *Roses*; he afterwards planted the whole 40-acre field. In 1889 the Old Exotic Nursery, Canterbury (which was carried on for many years by the father of the late Dr. Masters), came into the market. This Mr. Mount purchased and carried on for many years. In 1893 he was invited by the late Lord Radnor to open a nursery at Folkestone, which he has carried on ever since; in 1898 a nursery was opened at Herne Bay, which is still held; in 1897 and 1898 60 acres of adjoining land were taken, being part of Beverley Farm, which makes the total nursery ground at St. Dunstons to 100 acres. In 1902 he

purchased 170 acres of land near St. Martins, Canterbury, being part of the Barton Court estate, which is now planted with fruit and Hops; in 1904 he hired 270 acres of land, being Woolton Farm, near Canterbury, which is now planted largely with fruit and Hops, a small portion being arable; in 1907 he took Hode Farm, 267 acres, which is being planted up with fruit largely, the rest being Hops and arable land; he also hired 60 acres of land adjoining the Barton estate, which is being used for nursery work, being planted up with *Paradise* and other stocks for fruit trees, and seedling Briar and other stocks for *Roses*, the total holding being now over 500 acres. There are ranges of glasshouses at Canterbury, Folkestone, and Herne Bay, with a total superficial area of 150,000 feet.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE FLOWERS OF SPENSER.—I thank Mr. Engleheart for his criticism on the word *Aquilegia* (p. 54). I know the derivation for *Aquilegus* and accepted it in my *Plant Lore of Shakespeare*. But I am now sure that I was wrong. There is no such Latin word as *aquilegia*, and I cannot find who invented it. The older word was *aquilina*, which is late Latin, but is retained in English in "aquiline nose." I can find no earlier mention of *aquilegia* than Gerard; he and Parkinson both use it, but in connection with *aquilina*. In 1623 Bauhin says: "*Aquilegia videtur dicta quasi aquilina ob floram mucronis adnatis aut sicut aquilini ungues*" (*Pinar* 144). But Linneus' account is decisive. Among his "*nomina perversa, ex errore lectione veterum*" he has "*aquilegia pro aquilina*." This is enough for me, so that *pace* Messrs. Engleheart and Wolley-Dod I shall stick to *aquila*. In all the European names of the plant the reference is to *aquila* and not *agua*, and the history of *aquilegia* is very simple: *Aquila*, *aqueila*, *aquileia*, *aquilegia*. I knew Mr. Wolley-Dod well; he was a good scholar, but he was not infallible. I should like to add that I should be very thankful for any notes or criticism on the Spenser papers. I have taken a good deal of trouble with them, but "*humanum est errare*." *Henry N. Elliott*.

THE R.H.S. AND ITS JUDGES.—There are some things said that were best left unsaid; and some things it is needful to say that are said at the wrong time. I hardly know into which of these categories to place the remarks as to a pecuniary nature made by one speaker at the otherwise very pleasant luncheon and social function to which the Council invited the members of the committees, the judges, and others at the recent Holland Park show. The speaker in question might, with all due propriety, as one of the judges, have thanked the Council for the concession made to him and others in paying their necessary travelling and similar expenses, and have then been content to express a hope that other favours might in time be extended. Certainly the R.H.S. does differ from horticultural societies generally in relation to judges' fees; but, still, many national societies enlist the services of judges without payment of fees, hence the R.H.S. is not alone in that respect. But no similar society is so wealthy, and it is knowledge of that fact doubtless which led to the appeal for fees to judges, in addition to the payment of travelling expenses. But whilst the R.H.S. needs the service of judges but few times in the year, it needs the service of members of its committees at some 23 ordinary meetings, at several special meetings at Wisley, and, more or less, at least at three great shows, making some 30 occasions in each year. Now, the attendance at meetings or shows each year is usually good, and if any member attends but 20 times out of the whole, at a cost of, say, but 4s. each time, he has, in the discharge of his duties, to expend, beyond his annual subscription, at least 44 each year. Some members attend even oftener, hence to them the needful attendance involves during the year a considerable outlay. But I do not

know that they ever complain or ask for out-of-pocket expenses, much less for fees. These members do what they do for the love of horticulture, for their regard for the Society, and as some return for the honour shown them in being invited to be one members of the committees. Thus, it constant in the discharge of their duties, they incur greater expenses than do those judges who come to shows perhaps twice a year. If the Council could place a light luncheon at the disposal of members of the committee each meeting, that would be a singularly acceptable concession, as a lunch usually costs more than travelling. In paying rail fares from Waterloo to Weybridge and back, also in providing a conveyance from Weybridge to Wisley, and giving members a lunch, the Council has done very much to earn members' thanks. It is in such directions so much can be done to secure loyal co-operation. *A Member of a Committee.*

A NEW HYBRID PEONY (P. SOUVENIR DE MAXIME CORNU).—In the second part of the *Revue Horticole* for July, the editor, Monsieur D. Boss, describes and illustrates by a woodcut an apparently most beautiful hybrid Peony, which has been obtained by M. Louis Henry by crossing the yellow tree Peony *Delavayi* with the pollen of one of the fine forms of *P. mouatan* named *Ville de St. Denis*, the colour of whose flowers is white more or less shaded and spotted with violet-carmine. This slightly from the hybrid obtained by this razer, the pollen parent of the first (named *Mme. Louis Henry*) being another Moutan variety named *Elisabeth*. The first hybrid was figured on a coloured plate in the *Revue Horticole* last year and described on pages 322 and 544. The later hybrid, which is to bear the name of Professor *Maxime Cornu*, late director of the *Jardin des Plantes*, is apparently a much larger and more beautiful flower than *Mme. L. Henry*, being from 10 to 18 centimetres in diameter and very double; the flowers are of a pale, canary-yellow, lightly tipped with carmine at their extremities and sometimes also at the bases of the petals; this also appears in the fine form of the parent *P. lutea* or *Delavayi superba*. The plant produced five flowers, three of which were on the terminal extremities of the shoots and the other two on the laterals. The terminal flowers were slightly larger in size than the others. The shade of colour also of the smaller flowers differed slightly from the first, being of a rather greenish hue, with the carmine shading more accentuated and spreading more over the petal; the stems of the new variety being of a much more woody nature than the first hybrid. As propagation is expected to be easy and rapid, it is to be hoped that so fine a plant will ere many years be obtainable by the public. *W. E. Gumbelton.*

TOMATO NEW DWARF RED.—It is somewhat difficult to appraise the value of a new Tomato, because of the many excellent kinds already in cultivation, but the variety under notice is so excellent a cropper, and the fruits are so good in quality, that it is worthy of special notice. For a private garden it is an ideal variety on account of its dwarf habit, free cropping and good flavour. I recently saw a large number of plants of this variety laden with ripe fruits, the latter being excellent both as regards shape and colour. The fruits are very solid, and have remarkably few seeds. Owing to its dwarf character it can be cultivated in a small house or pit. It greatly resembles *Acquisition*, which is one of its parents, but it is far in advance of that variety, both in regard to crop and edible quality. I do not know of any Tomato that sets more freely than new *Dwarf Red*, and this makes it a most valuable winter variety. The fruits are borne in clusters of from six to eight fruits, and quite close on the stem. The plants average about 3 feet in height, and the first fruits are produced close to the base. As a variety for cultivating in the open it is excellent, as the plants crop early and produce fruits freely. *G. H. Pyle.*

CORIARIA JAPONICA.—In a reference to this species in your last issue (see p. 43), in which I stated that it produced "amber-coloured fruits," I had obviously C. terminalis in mind. *C. japonica* has fruits of a violet or coral-red colour, and in their fully-ripe stage they assume a blackish hue. *E. H. Johnson.*

BIRDS ENTANGLED IN FRUIT NETS.—Will you allow me to suggest to your readers that they should make a practice, at this season of the year, of periodically visiting their fruit nets and so insure against such of our little songsters as many have been caught there dying a slow death by hunger and thirst? It is quite a common sight to see the dead body of a bird entangled among the meshes of a net, and although we all know how troublesome these little thieves are, we ought surely, if their despatch is necessary, to make it as swift and painless as possible, and not leave them to die a lingering death such as one does not like even to contemplate. *Missel Thrush.*

"FRENCH" MARKET GARDENING.—I am terribly disappointed with last week's *Gardener's Chronicle*. For some time past I have been reading with interest articles possessing such alluring titles as "Golden Sol," "4,000 (or was it only 4,000?) Profit per Acre," "The Secret of the Black Sol," &c., in the daily Press. For a halpenny per diem there is put at the disposal of readers the valuable secret of how, with little or no horticultural experience, the veriest tyro simply has to rent a small piece of ground and make an annual profit of many hundreds of pounds. The basis of it all seemed to be "soil as black as your hat"—one day though it was "black," but that is a detail. With soil of this productive colour Lettuces, Radishes, Carrots, and Turnips were produced in such astonishing numbers that, with the help of a few Melons as pot-boilers, the petite culturist's fortune was soon made. True, there are accessories, but simple ones, such as frames, lights, and cloches. In the same way news is given to the world at large of a new French discovery in the shape of straw mats for covering purposes. (My grandfather used to make them, but perhaps he was merely a "French" gardener, but this week's *Gardener's Chronicle* bids me pause and reconsider. In your "Answers to Correspondents" columns your expert on "French" gardening gives the net profit as about £60 or £70 per annum (per acre.—Ed.), and as the *Gardener's Chronicle* possesses a reputation for accuracy, I feel that perhaps it will be wiser to bear my intense disappointment at the alliance so suddenly snatched from my reach and remain an "English" gardener. *C. C. B.*

LILIUM JAPONICUM.—This beautiful and distinct Lily, the subject of a supplementary illustration in the *Gardener's Chronicle* for May 16, is far more generally known as *L. Kramerii*. We must, I suppose, on the ground of priority, accept *L. japonicum* as its correct title; but, as a Lily lover, I emphatically protest against classing *Alexandra* and *Colchesterii* as varieties of *L. japonicum*. The *Index Kewensis* is beyond my means, but the *Taxo Hand List* so places them; while in Mr. Baker's paper read at the Lily Conference, Colchester, it is regarded as a variety of *L. Brownii*, but *Alexandra* is referred to under the name of *L. japonicum*. Taking first the case of *L. Alexandra*, I fail to see in what respect it is related to *L. japonicum* (*L. Kramerii* of gardeners), except that they are both members of the same section of the genus *Lilium*. When it was first introduced under the name of *L. Ukeiyu*, this Lily was regarded as a hybrid between *L. auratum* and *L. longiflorum*, and its affinities are certainly more with these two *Liliums* than with *L. japonicum*. Taking its prominent features more in detail, the erect stem of *L. Alexandra* is clothed with rather pale green leaves, about 5 or 6 inches long and three-quarters of an inch or so in width, but they widen out just at the upper part of the stem. The flowers are shorter than those of *L. longiflorum*, and less showy than those of *L. auratum*, though in this, as in other features, there is a certain amount of variation. The flowers are clear white, shaded inside and outside with green, while the fragrance much resembles that

of *L. longiflorum*. The bulb, too, shows no particular affinity to *L. japonicum*, but in colour and shape it more closely resembles that of *L. longiflorum*. For a few years after its introduction we used to get a large number of bulbs of *L. Alexandra* from Japan, but recently the supply seems to have greatly fallen off. In claiming for *L. Alexandra* a well-marked distinctness from *L. japonicum*, it may be pointed out that all authorities concur in assigning specific rank to *L. rubellum*, a species which is very similar to *L. japonicum*. With regard to *Colchesterii* being classed as a variety of *L. japonicum*, it cannot, I think, be disputed by anyone that it is simply a form of *L. Brownii*. When in flower at Kew, I have frequently seen it so named. Mention of *L. Brownii* suggests the question: What is the typical species? It is said to have been first flowered by Brown, a nurseryman, at Slough, in 1837, but its origin is, I believe, unknown. At all events, *L. Brownii* has been for the last 40 years, and probably much longer, grown by the catch, and sent, along with other bulbs, to this country. The *Hand List* gives the native countries of *L. Brownii* as China and Japan; yet out of a great number of bulbs collected wild from both these countries that have for some years past come under my observation, I have never yet found *L. Brownii* as grown by the Dutch. The *L. Brownii* of Japanese nurserymen is *L. Colchesterii*, which, according to priority in nomenclature, should be known as *L. odorum*. *W.*

NERTERA DEPRESSA (see p. 25).—This plant needs only cold frame protection, and, given this, it is free in its growth, and seldom fails to set an abundant crop of its scarlet fruits. In former days, and especially when the so-called carpet bedding was in vogue, the plant was in great demand, examples well set with fruits selling literally by the hundred. At that time the stock of this species in one nursery garden was divided between the soft-wooded and hardy plant departments; but when it was seen that much the best examples were produced by the cold frame treatment, the entire stock was transferred to the hardy plant department. In the greenhouse the growth was too rampant, and the creeping stems becoming elongated, fruits were few. Plunged in sand in pots in a cold frame, the tufted growth remained, and there was a free set of berries. The plants were watered overhead at all seasons save the winter time, when little was required. At flowering time in spring the lights were drawn off entirely during the best part of the day. I have tried the plant in the open in sheltered places, but the spring frosts invariably ruined the flowers. *E. H. Jenkins.*

EVOLUTION AND SCIENCE.—The Darwin-Wallace jubilee meeting of the Linnean Society, on July 1, undoubtedly marked a most notable event in the history of natural science, and all must acknowledge that the impetus to biological research and knowledge which has resulted from the lines of investigation introduced by the new ideas first promulgated in 1858 fully justified such a celebration. But, at the same time, is there not some danger lest our jubilation should be considerably overdone, and that we should too easily satisfy ourselves that the brilliant and captivating hypothesis identified with the name of Mr. Darwin has led to more in the way of certain knowledge than is actually the case? No doubt, as is said in your article of the 11th inst.: "We have long since accepted the fact of evolution itself almost as a self-evident proposition, as an axiom of thought." But are we meanwhile any nearer agreement as to what "Evolution" exactly signifies—by what agencies and through what processes it has been brought about? And until we have something approaching a certainty upon this point, can it be said that we have made any substantial progress towards a solution of the problem? Quite recently, in his Gifford Lectures for 1907, so high an authority as Herr Driesch has declared that "Everything about a real theory of phylogeny must be left to the taste of each author who writes on the theory of the Living." And he adds: "You may call that a very unscientific state of affairs, but no other is possible." There will, of course, be many who vehemently demur to such a verdict, but it seems at least to show that no conclusion has yet been reached which compels

scientific assent. As to the Darwinian explanation in particular, which on the occasion of the foregoing was naturally the theme of many distinguished speakers, it was proclaimed by one, whose utterances cannot fail to carry weight, that the main lines of the theory of Darwin and Wallace remain unchanged. But the main—the essential—factor upon which they both relied for the work of evolution was undoubtedly the action of Natural Selection, or the survival of the fittest in the struggle for existence; and who will say that this is now universally, or even generally, regarded as an adequate explanation of the transformation which organic life is held to have undergone? More than 20 years ago, the late Professor Romanes declared that, "At present it would be impossible to find any working naturalist who supposes that survival of the fittest is competent to explain all the phenomena of species formation"; and it will hardly be pretended that since he spoke strong agreement on the subject has been attained. It is not, therefore, the wiser and more truly scientific course to refrain from glorying in what manifestly has not yet been achieved, and to acknowledge with Driesch, "We do not know very much about evolution at all . . . in this field we are just at the very beginning of what deserves the name of exact knowledge." *John Gerard, S.J., F.L.S.*

TWO-NATIVE FLOWERING PLANTS.—*Phytolacca spicata* is a handsome plant, the lower leaves being cordate acuminate in shape and slightly indented at their margins. The flowers are pale blue, and form a dense spike 2 or 3 inches in length. This charming plant attains to a height of from 1½ to 2 feet, and is especially suited for cultivation in the foreground of an herbaceous border. The plant is wild in some parts of England, being found in hilly pastures and woods of eastern Sussex. *P. orbiculata*—another very ornamental plant—may be found growing wild on the chalk downs from Kent to Wilts. It is of slightly decumbent habit, from 6 to 18 inches in height. The radical or lower leaves are ovate and cordate, the upper ones narrow and sessile. The flowers are deep blue in colour, and are borne in a globular terminal head of an inch or more in diameter. It is a suitable plant for the Alpine or rock garden, where it produces a pretty effect when in full bloom. Both these plants thrive in a mixture of good loam and sand; they require an abundance of moisture during hot, dry weather. *W. Glover, Langport.*

SOCIETIES.

ROYAL HORTICULTURAL.

JULY 21.—The Horticultural Hall, in which the meeting on the above date was held, displayed alterations in the arrangements, such as departures from those usually observed, were improvements. In the centre of the building Messrs. J. CARTER & Co. had erected a kind of temple, in which were effectively arranged great quantities of Sweet Peas in variety. Against the back wall of the hall, great oblong blocks of flowering plants, Palms, Ferns, and *Codiaeum* found places. The more noteworthy were *Fuchsias*, from Messrs. J. VEITCH & SONS; *PETUNIA*-flowering *Carnations*, shown by W. CUTBUSH & SONS, and a beautiful group of *Carnations*, *Lilies*, *Streptocarpus*, *Caladium*, *Verbenas*, &c., from the gardens of G. H. BROWN, Esq.

Floral Committee.

Present: H. B. MAY, Esq. (in the chair), and Messrs. C. T. DRURY, J. GREEN, T. W. TURNER, C. DIXON, W. A. BILNEY, R. HOOPER PEARSON, R. C. NOTCUTT, G. REUTHE, J. WALKER, W. HOWE, J. JENNINGS, H. J. JONES, A. TURNER, C. E. PEARSON, T. J. BENNETT-POE, W. CUTBUSH, E. H. JENKINS, W. F. JAMES, G. PAUL, J. DOUGLAS, G. GORDON, J. E. McLEOD, J. HUDSON, and J. W. BARR.

MESSRS. J. VEITCH & SONS, LTD., Royal Exotic Nursery, Chelsea, exhibited a table of miscellaneous plants, *viz.*, *Begonia* (Washington of compact habit, each plant surmounted with large corymbs of scarlet-coloured, double blooms, the plants, including the pots, measuring 1 foot in height; *Begonia* "Colonel Laussedat," having a dwarf habit of growth, double flowers, and marbled foliage; well-

bloomed young plants of *Exacum macranthum*, also *Loebelia Richardsonii*, very suitable for a basket plant; a number of vigorous specimens of *Solanum Wendlandii*, each surmounted by a large corymb of lilac flowers. This firm showed a dozen flower-heads of *Rhododendron javanico-jasminiflorum* hybrids, a few fine varieties of perpetual-flowering Carnations, including the varieties Miss Willmott, Jumo, Robt. Berkeley, Mandalay, Robt. Buchanan, and Earl Komig; and a fine, large-flowered *Canna*, *W. Saundersii*, in colour a glowing crimson, also Mrs. Kate Gray, large in size and of an orange-scarlet colour. Messrs. VEITCH also exhibited cut flowers of hardy border plants in much variety; and among the rarer or showier species, mention may be made of *Romneya Coulteri*, *Sedum kamtschaticum variegatum*, with pink-coloured flower-buds which, when open, disclose starchy blooms, the leaves are green, bordered with yellow, and *Campanula carpatica pelviformis* (see p. 20). Standing apart by itself, Messrs. VEITCH showed a group of Columnar-formed Fuchsias, some of them 10ft. in height. (Silver-Gilt Flora Medal.)

Messrs. WARE, LTD., Feltham, exhibited miscellaneous border flowers and rare Alpine plants. The *Phlox decussata* varieties, if not in great numbers, were notable for large size of truss and brilliant colouring. The blooms of *Echinacea intermedia* were large and very showy; *Chrysanthemum King Edward VII.* and *Agrostemma hybrida* were also shown. (Silver Flora Medal.)

Messrs. BARR & SOSS, King Street, Covent Garden, London, made a large display with cut blooms of hardy border plants, and noteworthy among them were *Potentilla*, *Vase d'Or*, *Sidalcea Rosy Gem*, *Platycodon grandiflorum*, *Phlox decussata* in fine varieties, *Astilbe chinensis Davidii*, and *Water Lilies*.

Mr. AMOS PERRY, Hardy Plant Farm, Enfield, made an extensive show of *Water Lilies* and cut blooms of hardy border plants. Very showy were *Lychnis cognata*, large, and of a brilliant scarlet colour; *L. Haageana* hybrids exhibited colours differing in the shades of scarlet. *Liliums* were shown in considerable numbers, and made a fine show of colour. Great stems of *Senecio macrophylla*, surmounted with yellow-coloured flower heads, were conspicuous objects. *Chrysanthemum maximum* in variety formed a large part of the exhibit. (Silver Flora Medal.)

Mr. MAURICE PRICHARD, nurseryman, Christchurch, Hants, exhibited cut blooms of hardy herbaceous perennials, and among them we noted *Campanula Isabel*, a rich blue-purple flower, some very finely-torned and coloured *Gladioli*, excellent shrubby *Phloxes*, *Hemerocallis Baronii*, and a fruiting branch of *Coriaria japonica* laden with ripe red fruits. (Silver Flora Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park, Middlesex, showed *Buddleia variabilis* Veitchii, and a variety named *magnifica* having large racemes; *Solanum Wendlandii*, *Swainsonia splendens*, a quantity of perpetual-flowering Carnations in tall and short glasses, making an excellent effect of themselves. (Silver Flora Medal.)

Mr. G. REUTHE, Fox Hill Nursery, Keston, showed in abundance cut flowers of hardy herbaceous perennials—*Phlox decussata*, *Campanulas*, *Chrysanthemum maximum*, *Lilies*, and *Shirley Poppies* forming the major proportion of the flowers. (Silver Flora Medal.)

The fine display made by Messrs. J. CARTER & Co., reference to which has already been made, consisted of choice varieties of Sweet Peas, and formed a pleasing feature facing the main entrance to the hall.

Messrs. JAS. CARTER & Co. also showed nine plants of *Eschscholzia The Mikado*, a scarlet variety outside and inside. (Silver-Gilt Banksian Medal.)

Messrs. W. BULL & SOSS, King's Road, Chelsea, showed a number of stove plants, mostly consisting of such as possess coloured or variegated foliage. We remarked *Bertolonias*, *Dorstenia argentea*, *Dracaenas*, *Codiaeums*, *Aglaonema versicolor*, and *Caladiums*.

Messrs. W. CUTBUSH & SON, Highgate, made an imposing exhibit with Carnations in tall vases and in pots on metal stands, the flowers cut with the longest possible stalks, as is now the vogue. Between these tall stands and glasses

dwarf bouquets of Carnations were placed, with ample space between them. This firm showed a miscellaneous plant group set up in close array. It consisted of *Lilies*, *Dracaenas*, *Codiaeums*, Carnations, *Caladiums*, *Verbena* Miss Willmott, &c. (Silver Flora Medal.)

Messrs. EGGETT & SON, Thames Ditton, showed a small exhibit of Ferns.

Messrs. KELWAY & SON, Langport, Somerset, made a fine display with *Gladioli*.

Messrs. PHILLIPS & TAYLOR, Lily Hill Nurseries, Bracknell, showed Carnations, many of them in fine form, of which Roy Morris, Touchstone, Ida, Mrs. Kearley, Desdemona, and Red Rover were examples of note.

Messrs. R. & G. CUTBERT, Southgate, showed pink-coloured *Astilbes*, and *Humea elegans*, the latter as large healthy plants. A Cultural Commendation was given for the *Humeas*.

Messrs. G. BUNYARD & Co., LTD., Maidstone, had a large exhibit of cut flowers of hardy perennials, among which we remarked *Pentstemon digitalis*, *P. Southgate Gem* (bright scarlet), *P. Newbury Gem* (darker in the tint but smaller), *P. Thos. Shaw* (scarlet exserted in white in the throat), *Shrubby Phloxes*, *Astromertras*, *Ceroisopsis* and *Helenium*. (Silver Flora Medal.)

Messrs. H. CANNELL & SOSS, Swanley, Kent, showed plants of *Begonia Washington*, *Hydrangea grandiflora alba*, well bloomed, in 5-inch pots, &c.

Mr. A. F. DUTTON, The Nurseries, Iver, Bucks., exhibited perpetual-flowering Carnations in immense variety, occupying a table half the length of the hall, and also apart at the east end of the same. (Silver-Gilt Banksian Medal.)

Messrs. H. B. MAY & SOSS, The Nurseries, Upper Edmonton, exhibited *Lozas* in note, including *L. Williamsii* and *aurantiaca*, capitally flowered; *Abutilon Nabob*, a crimson flower; *A. Golden Fleece*, lemon yellow; and *A. Triumphans*, of a light pink tint with marked veining; *Campanula isophylla superba*, nicely flowered, a useful plant; and well-flowered *Fuchsias* in many varieties. (Silver Flora Medal.)

Mr. J. DOUGLAS, Edenside, Great Bookham, had a notable exhibit of Carnations, self, fancy, and border varieties. (Silver Flora Medal.)

Messrs. SUTTON & SOSS, Reading, exhibited 40 plants of their fringed varieties of tuberous-rooted *Begonias*, in pink, yellow, scarlet, white, and other tints. In a few cases the blooms showed doubling to a minor degree and in others they were single. It is a showy strain, and the blooms are thrown well above the leaves.

HERR GEORG ARENDTS, nurseryman, Ronsdorf, Germany, showed *Astilbe Arendtsii* Venus, A. A. Cream Pearl, A. A. Ceres, A. A. Vesta, A. A. Pink Pearl, and some unnamed seedlings. All of these are of some shade of pink, and have the same erect habit of growth of varying degrees of strength.

LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton (gr. Mr. Jas. Hudson), showed flowers and foliage of *Nymphaea gigantea* var. *Hudsoniana*. The flowers measured 8 inches in diameter, had three rows of petals of varying lengths, and a yellow or amber hue. The colour is pale blue on the upper side, and darker hue on the lower. (Cultural Commendation.)

Messrs. WATKINS & SIMPSON, 12, Tavistock Street, Covent Garden, showed *Nemesia Triumph* in various colours. It is compact in growth and very free to flower.

G. H. BROWN, Esq., Roehampton, arranged a ground group of stove and greenhouse plants. (Silver Flora Medal.)

AWARDS.

FIRST-CLASS CERTIFICATE.

Nelumbium speciosum var. *Ostris*.—This is a handsome variety, the shapely blossoms attaining to fully 10 inches in diameter. The somewhat cupped blossoms are made up of about 16 petals with white bases, and coloured a clear rose, which merges into a deeper tone at the extremities of the petals. The flowers, like the huge, peltate, orbicular leaves, are poised on tall stems, and this rendered singularly effective. A flower and leaf of this handsome aquatic were exhibited by LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton (gr. Mr. J. Hudson), and the variety was unanimously awarded a First-Class Certificate.

AWARDS OF MERIT.

Astilbe Arendtsii Ceres.—A deeply-coloured variety resembling that known as *Queen Alexandra*.

Astilbe Arendtsii Pink Pearl.—In this variety the blossoms do not appear to open so fully, the buds retaining their distinct colouring for a long period. These were exhibited by M. GEORG ARENDTS, Ronsdorf, Germany. They are said to have been raised from crosses made with *A. astiboides* and the newer species, *A. Davidii*.

Sinningia hybrida Dr. Maxwell T. Masters.—Said to be a bi-genetic hybrid between the *Gloxinia* and *Gesnera*, the hybrid somewhat resembling in its flowers the drooping type of *Gloxinia* of former years. The flowers are rose-coloured, drooping, and freely produced, the leaf petioles longer than in the *Gloxinia*, and the roundish ovate leaf-blades of a soft, silky nature. From Mr. ERNEST DENARY, Germany.

Begonia kewensis.—A white-flowered variety with drooping clusters of blossoms appearing from nearly horizontally-disposed stems. The plant is suitable for growing in baskets. From Messrs. JAMES VEITCH & SOSS, LTD., Chelsea.

Coriaria japonica.—Some exceptionally good fruiting branches of this handsome species were shown. The fruits are reddish or coral at first, and when fully ripe assume a blackish hue. In the first-named stage they are singularly attractive, and appear from axillary clusters on the previous year's wood. The leaves are obovate, acuminate, deeply nerved. Exhibited by Mr. M. PRICHARD, Christchurch, Hants.

Rose Lady Godiva.—A pretty variety of the *Wichuriana* class, the double-flowered blossom being coloured a pleasing salmon-pink, a shade of colour seen in *Madame Abel Chateau*. From Messrs. PAUL & SOSS, Old Nurseries, Cheshunt.

Carnation Cardinal.—A border Carnation of much excellence and of perfect form. The colour is clear scarlet, and in this respect marks an advance in this class of flower.

Carnation Splendour.—Also a border variety of much merit; the colour is bright purple, and the form of the flower excellent.

Carnation Hercules.—Said to be a cross between an American tree variety and one of the *souvenir de la Malmaison* type. The flowers are very large, fragrant, of a crimson-maroon shade, and produced on long and stout stems. The calyx, too, is non-splitting. This large and showy variety, if lacking refinement, merits attention by reason of its parentage. These Carnations came from Mr. JAMES DOUGLAS, Great Bookham, Surrey.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshaw, W. Bolton, H. Ballantine, Gurney Wilson, H. A. Tracy, W. H. White, A. Dye, W. P. Bound, H. G. Alexander, J. Forster Alcock, A. A. McBean, Stuart Low, W. Boxall, H. Little, R. Brooman-White, and C. H. Curtis.

Mr. Col. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), had an excellent group composed of 16 grand specimens, all very fine examples of good cultivation, and including *Cattleya Warszewiczii* Othello, a magnificent variety of the *C. W. saturata* class, with a very fine rose-purple lip, showing but very small yellow spots on each side; *C. W. Lowii* variety of the same class, with two spikes of six and four flowers; a pretty *C. Warszewiczii* of the old type, with 15 flowers, and the beautiful *C. W. Frau Melanie Beyrodt*, with 22 large pure white flowers, with purplish-rose labellum, and for which a Cultural Commendation was justly awarded. Others in the group were two fine home-raised *Cattleya Hardiana*, two of *C. Lord Rothschild*, also raised at Westonbirt; *Miltonea vexillaria superba*, with 12 spikes bearing together 53 flowers; another fine light form of *Miltonea vexillaria*, two well-flowered *Platyclytus filiformis*, *Brasso-Cattleya Deibanoe Warszewiczii*, *Sophro-Lelia Ieta Orpheiana*, a large and good form of *Dendrobium regium*, hybrid *Odontoglossum*, &c. (Silver Flora Medal.)

Messrs. CHARLESWORTH & Co., Heaton, Bradford, staged a group of rare and interesting plants, a novelty being *Cattleya Semiramis* (Empress Frederick \times *labiata* Warner), comparable to the darkest *C. Fabia*, and with rich purplish-rose sepals and petals and deep ruby-crimson lip with gold lines at the base. Others noted were two finely-flowered *Ancistrochilus Thompsonianus* var. *Geitlii*, the rare *Odontoglossum Cro-Skinneri* album, *O. ardentissimum* album, *O. Gladys*, two *O. Eleanor*, *O. Schleiperianum citrinum*; plants of the handsome and fragrant *Oncidium Lanceaeum*, *Miltonia vexillaria albiflora*, with large white flowers; the singular *Bulbophyllum sarcocephalum*, various hybrid *Cattleyas*, *Odontoglossums*, &c. (Silver Banksian Medal.)

Messrs. HUGH LOW & Co., Enfield, had an effective little group, the central plant, at the highest point, being *Platyclinis filiformis*, with

W. M. APFLETON, Esq., Weston-super-Mare (gr. Mr. Brooks), showed *Cyrtopodium Vipanii roseum* (philippinense \times niveum) with white flowers having dotted rose-coloured lines.

The Right Hon. Lord ROTHSCHILD, Tring Park, Tring (gr. Mr. A. Dyer), showed a fine inflorescence of a pretty *Stanhopea* from Mexico, bearing ten flowers.

Sir TREVOR LAWRENCE, Bart., K.C.V.O., Burford (gr. Mr. W. H. White), showed *Laelia Bella* (*majalis* \times *purpurata*), a showy flower with a strong indication of *L. majalis*, and with deep rose-coloured sepals and petals showing the white ground colour at the base, the front of the lip and tips of the side lobes being bright mauve-purple. Sir TREVOR LAWRENCE showed three other new and rare species. (See Awards.)

J. FORSTER ALCOCK, Esq., Northchurch, again showed his hybrid *Sobralia* raised out of *S. Wiganiana*.

Odontioda Tiwatesni (*Cochlidia rutilanica* \times *Odontoglossum Harryanum*), from R. G. THWAITES, Esq., Chessington, Streatham (gr. Mr. Black). A very pretty hybrid with sepals and petals of a bronzy-claret colour, the lip being rosy-lilac with yellow crest. The plant, which was still small, bore an erect spike of five flowers and buds.

BOTANICAL CERTIFICATE.

Epidendrum costium, from Sir TREVOR LAWRENCE, Bart., K.C.V.O. (gr. Mr. W. H. White). A very remarkable species from Mexico, resembling in growth the *Barkeria* section, but much stronger, and with thick green leaves. The terminal nodding raceme consists of about 15 flowers, each nearly an inch across, the sepals and narrower petals being reddish brown with an acuminate yellow tip. Lip formed as in *E. pseud-epidendrum*, whitish, ridged, and blotched with purple.

Geodorum purpuratum, from Sir TREVOR LAWRENCE, Bart. A Himalayan species of *Bletia*-like growth. Inflorescence erect, drooping at the point. Flowers densely arranged; white with purple markings on the lip. Roxburgh described it as having rose-coloured flowers, but the plant shown agrees with the figure in King and Pantling's *Flora of the Sikkim Himalaya*.

Fruit and Vegetable Committee.

Present: George Bunyard, Esq. (chairman); and Messrs. J. Cheal, Geo. Woodward, J. Vert, A. Dean, A. M. Allan, G. Keli, G. Wythes, E. Beckett, O. D. Tuckett, J. Jacques, C. G. A. Nix, A. H. Pearson, and W. H. Divers.

Mr. J. ROSS, Handcourt Gardens, Upton-on-Severn, sent a Melon as a seedling variety; flesh scarlet, smooth and nice, but somewhat overripe.

Messrs. S. SPOONER & SONS, Hounstone, sent a tray of handsome, well-coloured fruit of the old Early Apple, red or summer, for eating, though not yet ripe. (Vote of Thanks.)

Mr. PALMER (gr. to W. P. BEALL, Esq., M.P., Basshill, Aylesbury) sent three named red Tomatoes as new—*Non-such*, *The Don*, and *Le Grande*. These were not different in taste, texture, or appearance from good varieties now in commerce.

Mr. R. STANNARD, The Gardens, Panshanger, Herts., had well podded plants of edible Peas, showing robust growth. These did not present any material advance on present-day varieties, of which there are myriads.

Messrs. CLIBRAN, of Manchester, sent a cluster of some four or five pods of a very long-podded Broad Bean. This was regarded as identical with the variety known as *Leviathan* or *Aquadulce*, the Beans in the pods being too thinly placed.

Messrs. JAS. VEITCH & SONS, Chelsea, set up a nice collection of 13 varieties of Cabbage Lettuces in trebles. The white, smooth-leaved forms were *All the Year Round*, *Acquisition*, and *Summer Face*. *Perfect Gem* was small, having green leaves, and *Royal Albert*, New York, and *Crystal Palace* had rough green leafage. The brown varieties were *Marvel*, *Brown Dutch*, and *Large Brown Summer*. (Vote of Thanks.)

Messrs. J. K. KING & SONS, Coggeshall, staged a collection of 60 varieties of Peas, many of them early and ripe, all from ordinary field culture. The best were *Quite Content*, *Telegraph*, *Duke of York*, *Duke of Albany*, *Twentieth Century*, *Progress*, *Lion*, *Kitchener*, *Gladstone*, *King's No. 1*, *Fillbasket*, *Lord Salisbury*, and *The Daisy*. (Vote of Thanks.)

Much the finest collection of Peas, however, came from Messrs. DOBBIE & Co., Mark's Tey, Essex, who set up in broad flat baskets 44 varieties, generally of the finest description. The stand was backed by numerous plants in pod, specially good being *Veitch's Perfection*, *Gladstone*, *Alderman*, *The Bell*, *Bystander*, of the *Gladstone* type, but greener, and *Stratagem*. Very fine, in baskets, were *Quite Content*, *Exhibition Marrowfat*, *Essex Wonder*, *Gladstone*, *Superlative Antocrat*, *The Bell*, *Duke of Albany*, *Gradus*, *Magnum Bonum*, *Ex Plus Ultra*, *Prince of Peas*, *Lord Roberts*, *Thos. Laxton*, *Senator*, *Sharpe's Queen*, *Prizewinner*, and *Fillbasket*. (Silver Knightian Medal.)

FIG. 20.—PORTION OF MESSRS. E. WEBB AND SONS' EXHIBIT AT THE WOLVERHAMPTON SHOW, WHICH WAS AWARDED A SILVER CUP. (See ante p. 58.)

40 drooping racemes of its pretty yellow flowers. In front were several *Oncidium Lanceaeum*, good *O. leucochilum*, the Swan Orchid (*Cycloches chlorochilon*), *Anguloa Clowesi*, *Lycaste Deppel*, and, among others, the handsome *Cattleya Mendeli* *Goliath*. (Silver Banksian Medal.)

W. P. BURKINSHAW, Esq., West Hill, Hestle, Hull (gr. Mr. J. T. Barker), showed *Cattleya Warszewiczii*, *Rochford's* variety, of the *C. W. saturata* class, in which the light yellow patches usually seen on the sides of the lip are almost obliterated. The plant was very finely grown, the spike bearing six flowers.

Mr. J. BIRCHENALL, Alderley Edge, Cheshire, showed *Bollea Lalandei* aurea, a light yellow flower; *B. L. pallida*, white, with faint blue markings, *Pescatoria Dayana*, and a small plant of *Polystachya pubescens*.

Messrs. J. VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea, showed *Cattleya Dusseldorferi* *Undine*, with fine pure white flowers.

AWARDS.

FIRST-CLASS CERTIFICATE.

Stanhopea tigrina superba, from Messrs. CHARLESWORTH & Co., Heaton, Bradford. First introduced by Messrs. Hugh Low & Co. from Mexico in 1839. It still remains one of the most remarkable of Orchids, its enormous pale yellow flowers heavily tinged and blotched with deep claret colour, rendering it a very striking object. The variety shown was an exceptionally large and richly-coloured form.

AWARDS OF MERIT.

Angraecum Anacutum (*Rolfe*), from Sir TREVOR LAWRENCE, Bart., K.C.V.O. (gr. Mr. W. H. White). A very remarkable species from N.E. Rhodesia, with thick, fleshy, light green, slightly glaucous leaves, quite unlike any other species; and long drooping raceme of pure white flowers, with nearly equal segments, and pale greenish-spurs about 6 inches in length, the flowers being nearest to those of *A. Kotschvi*. It was sent to Sir TREVOR LAWRENCE by Mr. Augustus Old.

COLCHESTER ROSE AND HORTICULTURAL.

JULY 8.—The annual show of this Society was held on this date in the Castle Park grounds, an ideal spot for the holding of a flower show. Unfortunately, the weather was wet, and this affected the attendance. Roses were contributed by the best exhibitors. In the amateur classes, Mr. O. G. ORPIN had remarkable success, having splendid blooms. In the Rose classes, the competition was very keen, but not much fruit was shown; vegetables were excellent. In the small classes the military competed largely and made a good show.

ROSES.

Many classes were devoted to these flowers. In those that were open to all exhibitors, remarkably good groups were staged, the competition being very close. The 1st prize for 42 distinct blooms of varieties was secured by Messrs. B. R. CANT & SONS, Messrs. PRIOR & SON being 2nd, and Messrs. FRANK CANT & Co. 3rd, all these being Colchester firms. In the class for 18 blooms of Tea or Noisette Roses, Messrs. B. R. CANT & SONS again won the 1st prize, but Messrs. F. CANT & Co. were 2nd, and Messrs. PRIOR & SON 3rd. For 24 garden or decorative Roses, the premier award was secured by Messrs. B. R. CANT & SONS with splendid blooms, Messrs. F. CANT & Co., being 2nd. The prize for the best Rose bloom in these classes was secured by Mess. S. B. R. CANT & SONS with a perfect bloom of Yvonne Vacherot. The amateur classes were good throughout. In the class for 18 distinct trusses, Mr. W. LEGGETT, Colchester, was 1st, with beautiful flowers; Mr. O. G. ORPIN, East Bergholt, being a close 2nd. In that for 12 Tea or Noisette Roses, Mr. O. G. ORPIN was 1st with fine blooms, and he also secured the Silver Medal given by the Mayoresse of Colchester. For garden or decorative Roses the Rev. J. H. PEMBERTON, Havering-atte-Bower, was awarded the 1st prize for flowers of great beauty; 2nd, Mr. O. G. ORPIN; 3rd, Hon. WM. LOWTHER, Campsea Ashe, Wickham Market. Dr. PALLETT, Earl's Colne, was 1st in the smaller classes, also taking a Silver Medal for the best Rose other than a Tea variety, having a very fine bloom of Frau Karl Druschki. Mr. O. G. ORPIN won the Colchester Medal offered for the best Tea Rose, with a grand bloom of Maman Cochet; the last-named exhibitor had also some splendid blooms of Bessie Brown. Other exhibitors of Roses were Dr. COOKE, Birch; Mrs. STANFORD, Braiswick; Capt. CANTLEY, Nowton Briars; Mr. COOKE, Polstead; Mr. BLYTH, Nayland, and Mr. DOW, Hakeston.

PLANTS.

There was a splendid group of plants from the gardens of Mr. HEATHERINGTON, Borechurch Hall, Colchester, and it won easily the 1st prize. 2nd, Mrs. LARSENT, Lexden. The best table of plants in pots was shown by the Rt. Hon. J. ROUND (gr. Mr. Bishop), Birch Hall, Theydon Bois; and Mr. P. W. OLLE, Colchester, being a good 2nd.

CUT FLOWERS.

These were staged in great quantities and of excellent quality. An important class was for 24 bunches of hardy garden flowers, and here Messrs. R. W. WALLACE & Co., Kilnfield Gardens, Colchester, won easily, with splendid specimens. 2nd, Mr. A. J. HARWOOD, Colchester. For 12 bunches of hardy cut flowers the Hon. W. LOWTHER (gr. Mr. Andrews) was awarded the 1st prize, and Dr. F. H. COOKE, Birch, the 2nd. The class for Sweet Peas was strongly contested, but some of the best flowers lost points by being crowded and badly arranged. Mr. T. CROSS was 1st in the large class, Messrs. SALTMARSH and E. W. KING & Co., Coggeshall, being 2nd and 3rd in the order of their names. In the smaller class for Sweet Peas Capt. CANTLEY and Major BRECKLE were the leading exhibitors.

FRUIT AND VEGETABLES.

The best collection of six dishes of fruit was shown by the Hon. W. LOWTHER (gr. Mr. Andrews); 2nd, Mr. OSBORNE. The 1st prize for Grapes was taken by Mr. ANDREWS with well-finished bunches of Black Hamburgh. Mr. T. OSBORNE had also the

largest bunches of Muscat of Alexandria, but the berries were not quite ripe. Mr. OSBORNE had the best Peaches and Nectarines. Mr. ANDREWS was 1st in all the three classes for Strawberries.

The vegetable classes were very closely contested, only two points separating the leading exhibits. The Rt. Hon. J. ROUND (gr. Mr. Bishop) was 1st for a collection of eight kinds, and he was closely followed by the Hon. J. LOWTHER, a weak dish of peas marring an otherwise excellent collection. The best collection of vegetables from market growers was staged by Mr. A. S. HARWOOD, Colchester. The best collection of salads came from Rt. Hon. JAS. ROUND.

The best 100 heads of Asparagus were shown by Mr. A. J. HARWOOD. There was a strong competition in all the smaller vegetable classes, the military in many instances showing well.

NON-COMPETITIVE EXHIBITS.

Messrs. WALLACE & Co., Colchester, arranged a splendid rock and water garden exhibit in the open on the slope under the eastern wall of the castle. Messrs. JOHN K. KING, Coggeshall, had a grand collection of Sweet Peas. Messrs. ABBOTT & SONS also had some 50 varieties of these flowers of splendid quality from their Ardleigh Nursery, and Messrs. E. W. KING, Coggeshall, also had very fine blooms. Messrs. BENTING had a choice group of Iris.

SCOTTISH HORTICULTURAL.

JULY 14.—Following on the paper upon the "Strawberry," read by Mr. Kidd at the monthly meeting on July 7, a conference on the Strawberry, with an exhibition of the fruit, was held on the 14th inst. in the Goold Hall, 5, St. Andrew Square, Edinburgh. About 50 dishes of fruit were exhibited, including the varieties Aberdeen Favorite, Dornoch, British Queen, Duke of Edinburgh, Dumbarton Castle, Elton Pine, Fillbasket, Garibaldi, Vicomtesse H. de Thuzy, King's Late Prolific, Grove End Scarlet, Dr. Hogg, The Laxton, Leader, President, Red Alpine, Reward, Royal Sovereign, John Ruskin, St. Antoine de Padou, Scarlet Queen, James Veitch, and Waterloo, the exhibitors being Messrs. ROBT. AITKEN, Loganbank (Midlothian); ALLAN BROWN, Edinburgh; R. H. COCKBURN, Gardiner (Perthshire); W. GALLOWAY, Gosford (East Lothian); A. MCKENZIE, Edinburgh; A. KINROSS, Clifton Park (Roxburghshire); C. MILLAR, Carron House (Stirlingshire); R. MOFFAT, Fordelcan (Midlothian); W. SMITH, Lambton Castle (Durhamshire); Mrs. VASS, Dalkeith (Midlothian); and Mr. JAS. WHYTOCK, Dalkeith House (Midlothian). The jurors were Messrs. J. Whytock (Dalkeith), W. G. Pirie (Dalhousie), and G. Sinclair (Prestonkirki). The best sample of Grove's Late Prolific was from Mr. SMITH; of Royal Sovereign from Mr. AITKEN; of Garibaldi from Mr. MOFFAT; of President from Mr. KINROSS; and of Dr. Hogg from Mr. COCKBURN.

Of the following varieties fine dishes were staged:—Leader (from Mr. GALLOWAY), Dumbarton Castle (from Mrs. VASS), Duke of Edinburgh (from Mr. MOFFAT), and British Queen (from Mr. COCKBURN). Mr. AITKEN sent a fine dish of Reward, which, for an extra large fruit the jurors pronounced to be of good flavour, and worthy of commendation. The jurors did not consider that any of the samples of Elton Pine shown were true to name, and they thought that one of the dishes of Dr. Hogg was also wrongly named. Royal Sovereign and Dumbarton Castle they considered to be two of the best Strawberries grown.

On taking the chair, the president of the association referred to the disappointingly small number of dishes staged, but the audience was at one with him in attributing this to the dry weather, succeeded by the wet weather which had been experienced in most districts immediately prior to the conference. An interesting discussion regarding the merits of the various varieties, more especially as regards their adaptability for growing in different districts and their value for market purposes, as well as questions of nomenclature, followed, the speakers including the president and Messrs. SMITH, GALLOWAY, CHATTIE, BETTY MASSIE, and GRIEVE. A meeting of the adjudicating committee was also held on this date, Mr. Whytock, the

convener, being in the chair. Six new varieties of culinary Peas, viz., W. H. MASSIE, D. E. LAIRD, JAS. STAWARD, JAS. WELSH, W. STAWARD, and James Grieve were submitted to the committee for their opinion, and it was unanimously agreed to award First-Class Certificates to W. H. MASSIE, D. P. LAIRD, and JAS. STAWARD, and Certificates of Merit to James Welsh, W. Staward, and James Grieve. The Peas were raised by Mr. R. STAWARD, Panshanger Gardens, Hertford. A Certificate of Merit was also granted to "Strawberry Reward," exhibited by Mr. AITKEN at the conference.

The annual excursion of the association took place on Saturday, July 18, when a party of over twenty of the office-bearers and members journeyed to Drummond Castle, the seat of the Earl of Ancaster. At Crieff they were joined by contingents from the Dundee and Broughty Ferry Associations, and also by a few members of the Bridge of Earn Society, making in all a party of forty. The weather being fine, the famous gardens were seen under favourable conditions, and the trip was greatly enjoyed.

GLOUCESTERSHIRE ROSE.

JULY 14.—The twentieth annual exhibition of the Gloucestershire Rose Society was held on the Spa Cricket Ground, Gloucester, on the above date, and proved an all-round success. The entries numbered 150, about the same number as last year. With regard to the quality of the Roses, in many instances it was not so good as last year, the recent heavy rains and boisterous winds having damaged many of the blooms.

For the first time in the history of the Society classes were arranged for Sweet Peas. Most of the leading raisers and growers in the country were represented in this section, and the display was a comprehensive and attractive one.

Mr. W. H. PICKFORD won the piece of Plate given by the Mayor and Corporation of Gloucester for the best display of Roses by an amateur residing in the city. In the Gloucestershire amateur classes, Mr. W. G. BONNOR, of Barnwood, Gloucester, secured the piece of Plate presented by Messrs. JEFFERIES & SON, Cirencester, for 15 varieties. Mr. J. H. CROXFORD was awarded the City High Sheriff's piece of Plate offered to Gloucester amateurs for six varieties of Roses. In the cottagers' classes, pieces of Plate were presented by Mr. Henry Telford, N.C., and Mr. J. H. CROXFORD, and these were won by Mr. A. MORTIMER, Tuffley; Mr. C. NEECHAM, Saintsbridge; and Mr. J. G. ORPIN, Gloucester.

The National Rose Society's Silver Medals for the best Roses exhibited by an amateur were awarded to Mr. R. FOLEY HOBBS, Worcester, for a bloom of Mrs. Theodore Roosevelt; Mrs. BONNOR, Barnwood, for White Maman Cochet; and Mr. J. G. ORPIN, Gloucester, for Pessie Brown.

In the nurserymen's classes Messrs. ALEX. DICKSON & SON, Ltd., Newtownards, and HENRY DREW, Longworth, each carried off a couple of 1st prizes, and Messrs. J. JEFFERIES & SON, Cirencester, the 1st prize for 36 varieties. In the open classes Messrs. ALEX. DICKSON & SON and Messrs. JOHN JEFFERIES & SON each won two first prizes. Messrs. J. JEFFERIES & SON'S Lady M. Bathurst, a new Rose distributed by this firm, and which has received commendation from the National Rose Society, figured conspicuously in Mrs. W. H. PICKFORD'S prize-winning basket.

In the amateur classes (open), Mr. F. DENNISON, Kenilworth, won the 1st prize for 24 varieties, with Mr. R. FOLEY HOBBS, Worcester, and Mr. CONWAY JONES, Gloucester, 2nd and 3rd respectively. For 12 varieties, three blooms of each variety, the prize winners were in the same order, but in the classes for 12 varieties, single blooms, for six Teas and for one bunch of garden Roses, Mr. CONWAY JONES took the three premier honours.

In the Sweet Pea section, the 1st prizes for Gloucestershire amateurs were won by Mr. W. J. THORPE, of Incecloote (18 varieties), and Mr. G. R. BONNOR, Barnwood (12 varieties), and for amateurs residing in Gloucester, Mr. W. H. PICKFORD secured the 1st prize. Miss MRS. G. SANDHURST, Gloucester, was awarded premier honours for the best display of Sweet Peas.

BIRMINGHAM BOTANICAL AND HORTICULTURAL.

JULY 15.—The midsummer flower show of the above Society was held at the Edgbaston Botanical Gardens on this date, and was a great success. The weather was fine, and visitors were more numerous than at any of the Society's previous special shows.

The Right Hon. **JOSEPH CHAMBERLAIN, M.P.**, Highbury, Birmingham (gr. Mr. John Deacon), sent a large and very well-grown group of "Malmaison" and Tree Carnations. The last-named were arranged along the back of the group, and the "Malmaison" varieties were placed in batches of different sizes in front. The flowers were large, shapely, and of good colours. (Gold Medal.)

From Messrs. **BAKER'S**, Wolverhampton, came a grand display of Roses, Sweet Peas, and Gladioli. Of Roses, René André, Captain Hayward, Frau Karl Druschki, Madame Abel Chateau, Marjorie, Countess of Derby, and Blush Rambler were well shown; and of Sweet Peas several excellent varieties were noted, including three new ones named A. B. Bantock, Earl of Plymouth, and G. W. Kerr. (Gold Medal.)

W. BYNG KENRICK, Esq., Somerset Road, Edgbaston (gr. Mr. Jas. Webb), showed a group of flowering plants, comprising double and single-flowered tuberous-rooting Begonias, *Francoa ramosa*, and a very good strain of *Gloxinias*. (Bronze Medal.)

Mr. C. H. HERBERT, Acocks Green, Birmingham, had a very showy group of hardy flowers, in which *Gaillardias*, *Campanulas*, *Liliums*, *Delphiniums*, &c., were shown in excellent condition; also *Verbenas* in variety and *Zonal Pelargonium* Paul Crampel, bearing large handsome trusses of flowers. (Silver-Gilt Medal.)

Mr. A. R. BROWN, Wyehall Lane, King's Norton, sent Roses and a choice selection of Carnations. (Bronze Medal.)

Mr. ROBERT SYDNHAM, Tenby Street, Birmingham, contributed a pleasing display of Gladioli and Sweet Peas. (Silver Medal.)

Mr. W. H. MORIER, Cannon Hill Park, Birmingham, sent three very large plants of *Neprolepis todeoides*. (Vote of Thanks.)

Messrs. W. H. SIMPSON & SON, Monument Road, Birmingham, had a beautiful collection of Sweet Peas, in which the varieties Miss Audrey Crier, Princess Victoria, Mrs. Henry Bell, Nora Unwin, and Frank Dolby were of exceptional merit. (Silver Medal.)

Messrs. RICHARD SMITH & Co., Worcester, sent an extensive group of Roses, Sweet Peas, and miscellaneous border flowers. (Silver Medal.)

Messrs. HEATH & Co., Cheltenham, had an arrangement of Alpine plants and border flowers. (Bronze Medal.)

SWEET PEAS.

In a class provided for nine varieties of Sweet Peas there were six exhibitors. The 1st prize was awarded to **A. HUGHES, Esq.**, Packwood Grange, Knowle (gr. Mr. T. Parry), who had a splendid lot of flowers. 2nd, **Mr. W. MARPLE**, Penkridge.

AWARDS OF MERIT

were granted to a variety of Pink known as Progress; a strong-growing variety, with unusually large, light-purple flowers borne on tall, strong stems; and *Galega officinalis* Her Majesty, which differs from the type by reason of its stronger growth, larger and deeper-coloured flowers borne on very long racemes. These were shown by **Mr. C. H. HERBERT**, Acocks Green.

BRITISH GARDENERS' ASSOCIATION.

The next visit of the London Branch will be to Finsbury and Waterlow Parks on Saturday, August 8. Members will assemble at Station Gates, Finsbury Park, at 3.30 for 3.40 p.m.

All professional gardeners are invited. Those unable to join the party at the appointed hour will on enquiry be informed of the direction which the party has taken.

The visitors expect to arrive at Waterlow Park 6.30 p.m.

Obituary.

RICHARD LOWE.—We regret to record the death of Mr. Richard Lowe, who, for a period of more than half a century, carried on business as a nurseryman and seedsman in Wolverhampton. His death took place on Monday, July 6, at his residence, Sandy Lane, Tettenhall, at the

THE LATE RICHARD LOWE.

advanced age of 81 years. The late Mr. Lowe commenced his business career at a very early age. He went to Wolverhampton as a young man in the early forties to act as assistant to his aunt, Miss Jane Lowe, in the conduct of the old nursery business established by his uncle in Queen Square, and at nurseries in Chapel Ash and North Road, so far back as the year 1785. On the decease of the above-mentioned lady, Mr. Lowe—in conjunction with

THE LATE THOMAS HOGG, WHOSE DEATH WAS RECORDED ON ante p. 32.

a Mr. Mowbray, with whom he entered into partnership—purchased the business from Miss Lowe's executors. They worked together up to the middle of 1862, when the partnership was dissolved, and Mr. Mowbray was succeeded by Mr. Lowe's brother William, the partnership between them lasting until 1871. Mr. Richard Lowe then took over the business and continued

to carry it on in the old shop in Queen Square, and at his nurseries on the North Road, Penn Road, until the month of September, 1890. Deceased was a member of the committee of the old Wolverhampton Horticultural Society, which he largely helped to establish some 50 years ago. He was entrusted with the laying out of Molineux Grounds for the purpose of the Fine Arts and Industrial Exhibition, which was held there in the year 1869, and which proved an unqualified success. In the month of January, 1907, he was elected a pensioner of the Gardeners' Royal Benevolent Institution. He had held the position of honorary secretary of the Wolverhampton Auxiliary of that Institution for several years previously. Deceased was buried in Tettenhall Old Churchyard.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending July 18, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather—Cool and unsettled conditions were experienced over the whole kingdom, and except in the north of Scotland and the English Channel district the rain was extremely heavy. Thunderstorms occurred in almost all localities, but were more common over the eastern half of England than elsewhere.

The temperature was below the average, the deficit being greatest, about 3°, in England S.E. and S.W., and in Scotland E. The highest of the maxima were recorded on somewhat irregular dates, and varied from 74° in England E., 73° in the Midland Counties, and 72° in England S.E., to 67° in England S.W., in the English Channel, and Scotland N. On some days many of the maxima were below 65°, even in the south of England, and below 60° at some stations further north. The lowest of the minima, which were also recorded on irregular dates, ranged from 38° in England S.W. and 40° in Scotland E. and W., to 47° in England S.E., to 50° in England E., and to 51° in the English Channel. As a rule the nights were mild and many of the minimum temperatures were above the normal. The lowest readings reported from the thermometer on the grass were 31° at Llangunnarch Wells, 34° at Cockle Park, Morpeth, 35° at West Linton, and 36° at Burnley.

The mean temperature of the sea.—Compared with the corresponding week of last year the mean temperature of the water was low at nearly all the stations except those on the south and south-east coasts. The actual figures ranged from 62.6° at Margate, 62.4° at Eastbourne, 60.4° at Seaford, and 60.0° at Newquay, to 51° at the north-east coast of England and Wick, and to 50° at Aberdeen.

The rainfall greatly exceeded the average except in Scotland N., where there was very little, and in the English Channel. In many parts of England the fall was more than twice, and in England S.E. and E. more than three the average. Falls of an inch or more in one day were registered over a large portion of England, generally either early in the week or on Thursday. The largest quantities recorded on the ground in the 24 hours were 1.92 inches at Clacton-on-Sea, Felixstowe and Tanbridge Wells, 1.88 inches at Broadstairs, and 1.80 inches at Norwich; and on Thursday 1.37 inches at Clifton, 1.39 inches at Frestwith, and 1.02 inches at Arthington. On the same day 1.92 inches fell at Armagh. The highest totals for the week were 3.51 inches at Felixstowe, and 3.15 inches at Clacton-on-Sea.

The bright sunshine was very deficient generally, the percentage of the possible duration ranging from 33 in the English Channel and 24 in Ireland S., to 15 in the Midland Counties and England E., 12 in Ireland N., 8 in Scotland E., and 7 in Scotland N.

THE WEATHER IN GREAT BRITAIN.

Week ending July 22.

A cool, wet, and very gloomy week.—For nearly three weeks the days have remained cool for the time of year, the highest temperature in the thermometer screen on only three occasions exceeding 60°. The nights, however, during the same period have been mostly warm, the lowest reading indicated by the exposed thermometer being only 40°. Both at Land and 2 feet deep in the ground is at the present time about 4° colder than is reasonable. Rain fell on each of the first four days of the week, to the total depth of 1 inch—equivalent to a watering of nearly five gallons on each square yard of surface in my garden. Of that amount more than three gallons have passed through the bare soil percolation gauge, but the gauge on which short grass is growing has been in no way affected. The record of bright sunshine again proved very deficient, the average daily duration being only 24 hours a day, or less than half the usual quantity at this season. The winds were light, the mean velocity in my garden being 1.1 miles. The average amount of moisture in the air at 3 p.m. exceeded a reasonable quantity for that hour by as much as 10 per cent. *E. M., Berkshire, July 22, 1905.*

SCHEDULES RECEIVED.

Newport and District Chrysanthemum Society's 25th Annual Show, to be held on Thursday, November 5, 1905, in the Gymnasium, Newport. Secretary, Mr. H. Poole, 255, Morden Road, Newport.

The Thirtieth Annual Show of the Atrincham and District Chrysanthemum Society, to be held on Friday and Saturday, November 6 and 7, 1905, in the Drill Hall, Hale.

MARKETS.

COVENT GARDEN, July 22.

(We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.)

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices. Includes items like Alstroemerias, Calla aethiopica, Carnations, and various roses.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and their prices. Includes items like Adiantum cuneatum, Asparagus plumosus, and Berberis.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various plants in pots and their prices. Includes items like Anemolopsis Veitchii, Aralia Sieboldii, and Arcautaria excelsa.

Plants in Pots, &c.: Average Wholesale Prices (Contd.).

Table listing various plants in pots (continued) and their prices. Includes Rhodanthe, Roses, and Verbena.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices. Includes Apples, Apricots, Avocados, and various berries.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices. Includes Artichokes, Beans, Broad, and various cabbages.

REMARKS.—There still continues a good demand for English and French Blackberries and prices have advanced considerably. Cherries are turning a better color, consequently they show a slight improvement in price. A few Apples are arriving from Kent, and a heavy crop of this fruit is anticipated this season. English Lettuce is but a poor dealer, the best samples realizing good prices. Nectarines are scarce and the prices high. There are some excellent samples of dessert Gooseberries packed in small boxes containing 12, on the market, and they are making good prices. The price of Tomatoes is inclined to rise on account of the recent wet weather. English Tomatoes are plentiful, but the supply of foreign is scarce, and it is doubtful whether the average price has been equal to 6d. and 8d. per dozen. English and Guernsey Beans are a poor trade, 3d. and 4d. per lb. are the highest prices obtainable during the present season. The supply of marrow Marrows is exhausted. Trade generally is fairly good. E. H. R., Covent Garden, Wednesday, July 22, 1908.

Potatoes.

Table listing various potato varieties and their prices. Includes Kents, Snowdrops, and Sharpe's Express.

REMARKS.—The supply of old tubers is exhausted. Trade is slow. Edward J. Newbery, Covent Garden and St. Pancras, July 22, 1908.

COVENT GARDEN FLOWER MARKET.

Before the next report appears the market will only be open three days a week for the sale of plants, viz. Tuesdays, Thursdays, and Saturdays, and will be open on by-mornings from 7 to 9 a.m.

POT PLANTS. Fuchsias are most abundant, and Zonal also show or the Pelargoniums are plentiful and good; Ivy-leaved varieties are becoming scarce. White Marguerites which have been plentiful, are now in most instances, of poor quality, and yellow varieties are scarce. The yellow (Crysanthemums) are good, but most growers will have exhausted their stocks by the end of this week. Mignonette is practically over. Rambler Roses are still procurable in medium sized, well-flowered plants. Liliums are good and include L. longiflorum and L. lancifolium (speciosum). Campanula isophylla alba is very good, also the blue variety. Coreopsis in plants is pretty. Heisteria, Collins, and other late spring plants are to be had, but there is little demand for them, and for all foliage plants there will be but little trade until September.

CUT FLOWERS.

The wet weather has been very disastrous for all hardy flowers. Sweet Pea flowers do not keep well after exposed to rains. Roses have suffered, but there are large supplies, and some are very good, yet extra special blooms are few and far between. Carnations are over-abundant and are at present well supplied. Lily of the Valley varies but little. Stephanotis, Tuberoses, etc., are well supplied. Gypsophila paniculata now shows a distinct color in the double variety this morning; G. elegans is also good, and Saponaria vicaria is seen. Spanish Irises are now nearly over, but the English varieties are good. A. H., Covent Garden, Wednesday, July 22, 1908.

DEBATING SOCIETIES.

GARDIFF GARDENERS'. Many members of this Society availed themselves of the invitation of Messrs. William Treseder to visit their City Nurseries, Landaff, on the 20th inst., where they were received and entertained by Messrs. F. and K. Treseder on behalf of the firm. Much time was spent in viewing the forest trees which, with a few exceptions, were raised from seeds sown in the nursery. The Japanese Larch was extremely fine notwithstanding the recent drought. R. T. W.

BURGESS HILL GARDENERS'. The members of this Association paid their annual visit to Cambrian Nurseries, by invitation of Mr. G. A. Hammond, on the 5th inst. The Haywards Heath Gardeners' Association were included in the invitation, and many members of this Society were also present. The attendance, consequently, was a record one. Mr. G. A. Hammond is an enthusiastic rosarian, and the time of the visit was most opportune, as the Roses were seen in their full beauty. Mr. and Mrs. Hammond entertained the members in an enthusiastic lawn, and the weather being delightful, the visit was most enjoyable.

CATALOGUES RECEIVED.

THE HULL CHEMICAL WORKS Co.—Horticultural sundries. GEORGE BUNARD & CO., Ltd., The Royal Nurseries, Maidstone—Straw Berries, Grape Vines, Figs, and other fruits. WILLIAM COOPER & NEPHEWS, Berkhamsstead—Aperite, a preparation for destroying insect and other pests on the soil. CHARLES TRENLER, Strath—Strawberries. G. MALLALY & CO., Cheddar—Bulb list. F. HERBERT CHAPMAN, Ryde—Narcissus.

FOREIGN.

VITAL-BEAUFORT, Boulogne—Horticultural sundries. LEON GAUTHIER, Caen—Strawberries. SOCIETE FRANCAISE DU LYSOL, Cluses, Seine—Lysol Preparations. M. HERNY Via Trivio 24-26, Naples—Bulls and seeds for autumn sowing.

GARDENING APPOINTMENTS.

(Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, it will be placed in our collecting box for the Gardeners' Club Fund, if such a contribution is received, and an acknowledgment made in these columns.) Mr. A. HERBERT, for the past 18 months Foreman in the Gardens at Leigh Park, Havant, under the late Mr. C. C. GARDNER, as Garden Superintendent, is now at the same place. (Thanks for 2s. 6d. for R.G.C. 11.) Mr. J. BLACKMORE, for the past 7 years Gardener to T. SIMPSON, Jany Esq., of Holloway, Putney Hill, London, is now Gardener to W. J. TAYLOR, Esq., The Vicarage, Epsom, near Cardiff. (Thanks for 1s. sent for R.G.C. 11.) Mr. A. COLLINS, for the past 16 months General Foreman at Woodlands Park, Leatherhead, Surrey, is now at Lady SARAH WILSON, Stud House, Hampton Court, Middlesex.

ACETYLENE GAS LIME: *E. P.* This material can be used as a manure to supply the constituent lime, but it should be placed in a heap exposed to the influence of the atmosphere for a month or two before being used. It is more suitable for heavy clay lands than for the lighter and more loamy soils, and it is also more adapted for coarse-growing plants, such as members of the Cabbage family than for Roses, or flowers generally. Another point to be observed is never to apply acetylene gas lime to land planted with P. latos, as it is apt to impart a very unpleasant flavour to the tubers. For Roses growing in a lime-deficient soil, use ordinary quicklime mixed with sulphate of magnesia (Epsom Salts), four parts of lime to one part of magnesia, and apply 6 ozs. of the mixture per square yard any time during the month of March. In using acetylene gas lime for the coarse varieties of plants on land deficient in lime, 8 ozs. per square yard may be trenching in some time previous to planting. We doubt if this substance will kill wireworm in the soil. For this purpose use ordinary gas lime.

A GARDENER AND BAILIFF'S NOTICE: *De Mot En Tib.* (1) Only the employer or some person duly authorised by him can give the notice of dismissal. (2) The employer can give notice without waiting to pay what may be due to you, but under your arrangement you can insist on payment at the end of the month of the amounts disbursed by you, irrespective of whether notice is given by either side. (3) A head gardener is usually entitled to a month's notice, but where he also performs the duties of bailiff, three months' notice does not seem unreasonable. It is, however, purely a question of the custom of the country, and you had better ascertain from other bailiffs what their evidence would be on this point if called upon as witnesses. (4) Your predecessor's agreement is not binding on you, though, possibly, the employer may endeavour to bring it forward as evidence of custom. (5) The proper remedy is to sue in the County Court, and if this becomes necessary you should instruct a local solicitor to issue the summons and represent you. *E. S.* As you are an under gardener and paid weekly, you are only entitled to a week's notice.

CATERPILLAR: *C. B.* The specimen you send is the caterpillar of the Death's Head Hawk Moth.

CHRYSANTHEMUM MRS. THOMPSON: *H. B.* It is now rather late for stopping the shoots, but if required for flowering in January and the plants can be grown under favourable conditions they might be stopped once more. If, however, the plants have already a fair number of shoots it would be safer not to do so. Much depends upon the conditions under which the plants are grown. Last winter many growers failed to flower the late varieties satisfactorily.

DOUBLE PETUNIAS: *G. T.* These may be propagated at any time when good cuttings can be obtained. The ends of the flowering growths be pinched off the plants will make new shoots from the lower part of the stems, and when these are about 2 inches long they will make good cuttings. Insert them in light, sandy loam and place them in a frame where there is a little bottom heat and a cool surface. They will soon root if the frame is kept closed for a time. The usual method of treating Petunias is to keep the plants in a cool house through the winter, and take the cuttings early in February or as soon as the plants have made new growth early in the year. The tops of the young plants may make better cuttings than those afforded by the older plants.

GRAPES DEFICIENT IN COLOUR: *F. H.* An application of iron sulphate will have little or no effect in producing a deeper colour in your black Grapes. The failure of the berries to colour is due to some cultural deficiency,

such as an insufficiency of fresh air in the vicinity or improper ripening of the wood. Train the lateral shoots well apart, so that air may circulate freely amongst the shoots, and do not overcover the vines with foliage. Supply water to the roots carefully, and do not stand pot plants on the borders, as the drainage water from these will do harm. When the Grapes are harvested, open the house to all ventilation possible, so that the wood may become firm and hard. Above all, avoid overcropping, which is the most frequent cause of a constitutional weakness in the vines.

GRAPES DISEASED: *H. H. B.* Some of the berries are affected with the "spot" disease, but most of them exhibit shanking. The latter condition is usually the result of some trouble at the root system, generally a badly-drained border. Renovate part of the border next winter, and be guided by the results as to whether it is advisable to remake the whole of the border in the following season.

INSECTS ON FRUIT TREES: *A. H. D.* We failed to find any of the creatures you describe. Your best plan will be to spray the trees with some arsenical insecticide such as Paris green, and in the winter to syringe them with the caustic soda solution. If you will send us some of the insects in a small box, we will endeavour to help you further.

MONSTERA FRUITS: *Correspondent.* The fruits of the Monstera after attaining their full size are several months before they show signs of ripening, but as you say the plant began to develop fruits twelve months ago these latter should now ripen. The size of the fruits you give is satisfactory; we have seen them larger, but that was on old plants. We would advise you now to keep the plants drier for a short time, and discontinue spraying them overhead; this will induce ripening. Once the fruits show signs of ripening they will finish in a few days. You can readily perceive when the fruits are approaching the ripening stage; they emit a strong but pleasant aroma, somewhat like a ripe Pineapple, and the outer portion of the fruit peels off, beginning at the stalk. The fruits should then be cut and placed on a dry warm shelf for a few days. They have a distinct Pineapple flavour and are very juicy. The only drawback in eating the fruits is that numerous small black spines are attached to the inside portion; these are disagreeable and being minute are difficult to remove; they are apt to cause a prickly or itching sensation in the throat.

NAMES OF FLOWERS, FRUITS AND PLANTS:—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon the time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time; they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *A. M.* *Inula glandulosa*—*Zola*. We do not undertake the naming of Roses. The other plant is *Levestera formosa*.—*Dick* 1, *Pracena marginata gracilis*, 2, *Pracena marginata*, 3, *Adiantum cuneatum* *Facottu*, 4, *Begonia Madame Anna Low*, 5, *Chelidonium majus*—*A. E. S.* *Stupella variegata*—*T. C.* *Tombidge*. *Melilotus officinalis*.—*W. T.* 19, *Campanula* species; 20, *Rhynchosyris retusa* (*Saccolabium guttatum*); 21, *Aerides virens*, very light form; 22 and 23, *Cypripedium barbatum*.—*Young Gardener*, 1, *Begonia argyrostigma*, warm greenhouse plant; 2, *Polystichum angulare*, hardy; 3, *Adiantum cuneatum* *Pacottu*, greenhouse; 4, *Galea officinalis*, hardy. *J. S.* *Onocleangolium inermis*.—*O. S.* 1, *Onocleangolium flexuosum*; 2, *Ocimum triquetrum*; 3, *Brassica verrucosa*; 4, *B. var. vermiculata*; 5, *Anthgonium gracile*; 6, *Dendrobium crispatum*.—*Reader*.

1, *Odontoglossum Adriane*, 2, *Oncidium raniferum*; 3, *Pleurothallis rubens*; 4, *Coclea macrostachya*; 5, *Oncidium sphacelatum*.—*Jury*. *Lyssimachia vulgaris*.—*F. Gray*. The plant could not name with greater certainty were it in flower. There is, however, but little doubt it is *Achillea vulgaris*, and therefore not a Strawberry plant.

PALM ROOT INFESTED WITH MEALY BUG: *IV. B.* The insects resembling mealy bug on the roots of your Palm are known as *Kipseria termitaria*. As yours is such a bad case, we should advise turning the plants out of the pots and washing the roots with warm water, but in the case of plants not so badly affected a little bisulphide of carbon should be poured into the soil. This is done by making holes at intervals with a piece of stout wire into which the liquid is poured. A teaspoonful of the chemical is sufficient for a pot of ordinary size.

PEA MALFORMED: *H. Z.* The example you send exhibits fasciation or fusion of growth. It is an ordinary garden variety. We cannot explain what has caused the abnormality.

SEED FOR NAMING: *R. T. L.* The very large seed is from the pod of a leguminous plant—*Entada scandens*.

TOMATO SPOT DISEASE: *Moseley*. See reply to *H. H.*, page 20, in the issue for July 4. The disease has no connection with the dressing of bonemeal used.

TREE INJURED BY LIGHTNING: *F. F.* As the damage does not appear to have extended for any considerable width, the tree will probably repair the injury by a callus or new growth from the sides of the bark that is split. Paint the wound with tar to exclude the wet and keep spores of fungus diseases from germinating and gaining an entry into the tissue of the tree. Keep the tree under observation, and if any decaying results, fill the crack with Portland cement.

UTILISING FORCING HOUSES: *G. K.* You do not mention whether the houses are span-roofed or lean-to, but, presumably, they are the latter, with a southern aspect, though that also you do not state. Have you had experience in the cultivation of any special produce? If not, a difficult task is before you in obtaining sufficient crops from two houses of the size named to provide you with a living. It would be advisable to take up some speciality and apply yourself to that thoroughly, as a mixture in such a small compass would never give good results, nor would you have sufficient produce for sale in large quantities, and you will find that few salesmen can deal profitably with small consignments of ordinary quality. Do not think of sending plants to London from your district; the cost would be prohibitive, and the markets are already well supplied with such produce. If you can find a good local market, one of the houses might be devoted to either Cucumbers or Carrots, and the other 15 Cucumbers or Tomatoes, making the selection in accordance with your experience as a grower, and with the demand of the district, which you must first ascertain. A portion of the latter house might be utilised for forcing *Seakale*, *Rhubarb*, or *Asparagus* early in the year, and when the plants are cleared from the other house, Cucumbers or Tomatoes could take their place for the late summer months; but there is not much profit in these crops at that season, and you might find it more advantageous to have a succession of Carnations. If you are starting the work without experience, as it would almost appear from your letter, we strongly advise you to have expert advice on the spot, as it may save you considerable expense and disappointment. Reliable salesmen advertise in these columns.

not so difficult to deal with. But what is really wanted is some cheap and really effective method of bird-scaring that can be as well adapted to the cottager's garden as to that of his well-to-do neighbour. Netting, which is practicable enough in some cases but quite impossible in others, is rather a laborious as well as an expensive business, and it is only those who are prepared to lay out a considerable sum of money on their gardens who can afford to adopt the more satisfactory and elaborate process of wiring in their fruit trees and bushes to protect them from the enemy. Ordinary tarred string netting is good so long as it is new, carefully put on and taken off, and arranged so that the crop can be gathered with a minimum of inconvenience, but most of us at one time or another have had trying experiences with closely-netted Strawberries and Gooseberries, or have broken our backs trying to gather the fruit while stooping under the protective canopy arranged overhead. Where large trees such as Cherries have to be protected, or the area of ground to be covered is considerable, netting is too costly or difficult a process to be worthy of consideration. Thread-work protection for seeds, flowers or bush-fruits when in bud is often successful up to a certain point, but here again the labour involved is considerable and the device is not always successful.

A good many of the old-fashioned bird-scarers seem to have gone out of fashion nowadays. We may dismiss the scarecrow at once as being quite out of place and much too disreputable for any well-ordered garden, but where are the terribly fierce-looking hawks that we used to see hovering over the Strawberry and Currant beds, and where are the bright three-cornered bits of looking-glass that used to be suspended amid the branches of the Apple-trees in days gone by? The former, if constantly moved from place to place, were not altogether without effect, especially when their jointed wings clattered in the breeze, and the latter were certainly effective for a time at least. Jingling tins that were hung so that they clanged together in the breeze soon lost their novelty from the birds' point of view, but were perpetually irritating to human ears. The same may be said for the dinner bell hung in the tree and agitated by the junior members of the family from the nursery window. Feathers or bits of coloured rag tied at intervals along a string impart a certain amount of terror to birds when the wind blows, but here again the effect is only fleeting.

Bird-scarers of a noisy character are, of course, the most effective, but even these are apt to lose their efficiency in the course of time. The mechanical gun is all very well, but a tremendous lot of fruit can be devoured between each report if these are only timed four or five to the hour, and if they are more frequent the birds get quite accustomed to them. Ordinary guns want somebody to look after them, and when a charge of shot happens to get in above the powder they are not at all desirable things in a garden where people are wont to wander. Take it on the whole, therefore, there is hardly any method of bird-scaring that is sufficiently effective to leave no room for something novel.

But there is one plan which has been adopted with some success, and since it costs

nothing is worthy of wider adoption. This is the cat system, and consists in the kennelling of the ordinary domestic grimalkin in the fruit bed or orchard. A long wire is strained between posts a considerable distance apart, and to it is attached a running chain or collar which the cat wears round her neck. [See Fig. in Gardeners' Chronicle, March 23, 1907, p. 189.—Ed.] Her bread and milk is placed at one post and her kennel—an old butter-tub with a handful of straw in it—at the other. The cat passes backwards and forwards perpetually, and as she does so rattles her chain and scares the birds. There is no cruelty in the system if the cat is taught to wear a collar when young and trained early, and a good active cat certainly enters into the fun of the thing, scampering along her wire whenever she sees a bird anywhere near. This method of bird-scaring may be recommended as a good one, but there is still room for some mechanical contrivance at a popular price, for even cats neglect their work at times. East Sussex.

NOTES FROM LA MORTOLA.

BRASSICA INSULARIS (MORRIS).

This is certainly one of the finest species of its genus, and can be considered as a highly decorative plant when in flower in early spring. It was first described and figured by Morris in his 77. Sard. 7 (1837), 168, t. xi. The plate, however well engraved, does not convey any idea of the beauty of the plant, as under cultivation in deep, rich soil it grows far more vigorously, and produces an immense quantity of flowers arranged in stout but elegant racemes. The individual flower is a very large one for its genus, and of a pure white. In fact, the whole plant forms a mass of white. Brassica insularis is a native of the Island of Sardinia, where it grows on calcareous or volcanic rocks. Seeds of it were received some time ago from the Botanic Garden at Cagliari, and have been distributed from this garden for several years. It is such a beautiful cabbage that it ought to be more cultivated. It shows off best where it cannot be seen too closely, so that the rather coarse leaves are not visible. Like all its congeners, it likes a rich and well-manured soil; in a barren place it hardly makes any progress. Alwin Berger, La Mortola, Ventimiglia, Italy.

CULTURAL MEMORANDA.

A METHOD OF PROPAGATING SCIADOPITYS.

The usual method of increasing Sciadopitys verticillata is by means of seed, and this is the only one usually mentioned in garden literature; but seeds are comparatively dear, and they vegetate less freely than those of most coniferous plants, besides taking a long period of time, and much attention. Grafting is much to be preferred to seed growing, grafted plants growing readily and making in four months plants equal in size to three-year-old seedlings. Early in March the terminal shoots are taken, and grafted on to pieces of the roots of the same species and bound round with oiled cotton wool; planted in small pots; and placed in a close house or frame having a temperature of 63° to 68° Fahr. When growth is completed, the plants should be hardened off, and by the beginning of the month of July the majority will be fit for planting in the nursery. The usual coating of the graft and root with grafting-wax or placing in an air-tight case are not required. Under this treatment the percentage of failures is very small. F. M.

BIRD-SCARING DEVICES.

CONSIDERING the enormous amount of damage committed by birds in the garden every season, it is somewhat surprising that so little ingenuity appears to have been displayed by inventors in the matter of an effective bird-scarer. One must admit that the subject is one of great difficulty, chiefly for the reason that familiarity breeds contempt, and birds are by no means slow in proving the truth of that well-worn maxim. Most of us have had plenty of experience as to this fact, and a bird's nest in a scarecrow's pocket or in the crown of its dilapidated hat is no uncommon thing. Perhaps the boldest thing of this kind that ever came within the writer's personal knowledge was a thrush's nest in the middle of a cherry-tree, the latter being already covered with a network of black thread to "scare the birds." In this instance, however, the bird paid the penalty of its temerity, for she was found one morning hanging dead in the tree, one of her legs entangled in the threads.

Various devices have, of course, been employed by gardeners from time immemorial to protect their crops from the birds, and where expense is not a consideration the matter is

OZOTHAMNUS ROSMARINIFOLIUS.

ALTHOUGH this pretty Australian evergreen shrub has been cultivated in this country for upwards of eighty years, it is by no means well represented in gardens generally. It forms a neat bush of free growth, with long slender shoots clothed with narrow Rosemary-like leaves about one inch in length, and in June and July bears corymbs or dense clusters of tiny white Aster or Daisy-like flowers at the apex of the branches and branchlets in such profusion as to justify the appellation of "Snow Flower," by which it is sometimes known (see figs. 32 and 33). Unfortunately, this species is not thoroughly hardy throughout the whole of the British Isles, but in the more favoured parts of the country it succeeds in the open air without protection.

By no means fastidious as regards soil, it prefers one consisting of rather stiff loam, to which peat and leaf-mould have been added, which should be made quite firm at planting time. Perfect drainage is essential. The best position is one having a south or south-west aspect, as it is only when the wood becomes thoroughly ripened that the best results are obtained. On no account should a position be selected that is exposed to cold winds, as the plant is apt to suffer in spring while growth is tender. Water should be given freely during hot, dry weather. In cold districts this species may be grown as a pot-plant for the embellishment of the greenhouse. It is very valuable for affording flowers for cutting, and they can be obtained with long stems for vases, being capable of remaining fresh for a long time. T. H.

ACHIMENES COCCINEA.

THIS is one of the original species of Achimenes, and was introduced to our gardens from Jamaica as long ago as 1778. In size of flower it does not approach the numerous garden varieties now in cultivation, but is nevertheless from its brightness of colouring well worthy a place in gardens. It succeeds when treated as a basket plant in a warm greenhouse, and so grown its small bright scarlet flowers render it an object of beauty throughout the summer months. When the highly ornamental flowers and the long blooming season of Achimenes in general are borne in mind, it is a matter for surprise that they are nowadays so little grown. Perhaps the fact that they are not of much value for cutting purposes is answerable for a good deal of this neglect, as invariably the first question asked concerning any new flowering plant is: will it be useful for a supply of cut bloom? W.

The Week's Work.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIBLING, Esq.,
Rear, Perthshire, N.B.

Narcissi for early forcing.—If it is intended to employ bulbs for early forcing, which are now growing in the open borders, these may now be lifted. Select only the best of the bulbs for this purpose. If they are required for decorative purposes the best plan is to put a considerable number of bulbs into an 8-inch pot. Each pot should be well drained and afterwards filled to half its depth with a compost of good loam, leaf-mould and sand. Place as many bulbs on this layer of soil as there is sufficient room for. Then fill up with soil to the top of the bulbs. Afterwards place as many bulbs between the top of the bottom layer as possible, and fill up again with soil, pressing it firmly around them. Although the bulbs in the bottom layer are so much lower in the pot than the others, they will all come into flower at the same time, grow to the same height, and, therefore, there will be a larger number of flowers in a given space. After the potting is completed, apply a good soaking of water, and place the pots in a position where they can be covered overhead with about 6 inches deep of ashes or sand.

Nerine Fothergillii major.—The bulbs which have been quite dry should now receive a little water, and as soon as the flower-spikes appear the supply of water should be increased; later, when the foliage also appears, the loose soil should be picked off from the surface and a

slight top dressing afforded. Nerines do not require to be repotted frequently, but any that do need a fresh rooting medium should be treated directly after the flowering stage is passed, taking the bulbs and shaking the soil away from them and repotting them into a compost of loam, leaf-mould, wood ashes and sand. The pots should be very carefully drained, and during the active growing season the plants may be given a free water supply. Immediately following the operation of repotting, the plants should be placed in a house of an intermediate temperature, where they can be shaded from the sun's rays during very bright weather, and syringed as often as necessary. As soon as the leaves begin to show signs of withering or decay the water supply should be gradually reduced and finally discontinued when the leaves have died quite away, at which time the pots may be

Queen Pineapples.—Plants from which the fruits have been gathered should have their leaves shortened, so that the suckers which have been reserved for the purpose of propagation may have plenty of room for developing. Careful attention must still be given to such routine matters as watering, manuring, syringing, and ventilating. A night temperature of 70° to 75°, with the usual increase by day, should be maintained, the aim being to secure stout, well-matured suckers possessed of short, broad leaves, and fit for potting by the beginning of September. Slender, elongated suckers, which are produced under unduly high and close atmospheric conditions, will not furnish the best fruits. Plants of young Queen Pines intended for fruiting next summer will now be growing freely and forming suckers; these should be removed as

[Photograph by Miss Wallace.]

FIG. 32.—FLOWERING SPRAY OF OZOTHAMNUS ROSMARINIFOLIUS: FLOWERS WHITE.

placed on a shelf exposed to the sunshine in a cool greenhouse, where they may rest until the following season.

FRUITS UNDER GLASS.

By T. COOMER, Gardener to LORD LLANGATTECK,
The Hendre, Monmouthshire.

The late Peach-house.—The fruits having now been finally thinned and the period of stoning passed should be fully exposed to the sun, in order to improve their flavour and colour. Keep the young wood properly thinned and trained, all lateral growths pinched out, and any extra vigorous shoots should be entirely removed. Ventilate the house freely, copiously water the borders as required, using diluted liquid manures often, and do not neglect to use the syringe.

soon as they are large enough to be grasped by a suitable pair of pincers. Examine the plants individually once a week, and water those that are in need of moisture with tepid water in which has been placed a small quantity of gauze. In cases where they are planted out, they must, of course, be watered collectively. Ventilate the pit early and tolerably freely on sunny days. Slightly shade the plants with thin tiffany, maintain a fairly moist atmosphere, and spray between the plants and overhead with tepid water when the house is closed early in the afternoon. It should, however, be borne in mind that much injury results from keeping the soil in the pots very wet, and this may be thoughtlessly done when syringing between and over the heads of the plants. Maintain a bottom heat of about 53°.

THE FLOWER GARDEN.

By W. FIFE, Gardener to Lady WASTAGE, Lockinge Park, Berkshire.

Flower beds.—Recent heavy rains having hardened the surface of the soil, it will be necessary to loosen this in order to prevent the ground cracking, and to admit more air to the roots of the plants. If a light mulching of leaf-mould be afterwards supplied it will be beneficial. Give frequent attention to pegging and tying the growths until the beds are completely finished, and when this has been accomplished continue to pinch and regulate the shoots in places where they are thinner than in other portions, never allowing a particular plant to grow beyond its proper limits. Free-flowering plants such as *Calceolarias*, *Verbenas*, *Violas*, *Lobelias*, require frequent waterings during dry weather. Remove all decayed flowers, never allowing the seeds to develop; thus prevent the plants being allowed to flower over a longer period. It has been necessary to give very careful attention to affording supports to *Dahlias* and other tall-growing plants, as recent winds would otherwise have caused damage. Sub-tropical plants appear vigorous and are very effective this season, and these species particularly need frequent attention in regard to protection from winds.

Winter bedding.—Evergreen shrubs that were removed from the flower beds last spring and will be required again for a similar purpose in the autumn must be given attention in the meantime. If they are constantly maintained in a moist condition, and the roots and the growths regulated and kept clean by syringing, they will lose their decorative appearance.

Lawns.—In dry districts, if the turf is getting brown, the mowing machine had better be discontinued for a time, using only the scythe for removing the coarser growing grasses as they appear above the ordinary level. Just now the Plantain is a conspicuous lawn weed, and should be at once eradicated in order that the bare patches may quickly become furnished with grasses.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. G. L. HOLBORN, C.B.O., G.I.E., Westonsair, Gloucestershire.

Cypripediums.—The species *C. Stoeckii*, *C. Rothschildianum*, *C. Sanderaianum*, *C. Curtisii*, *C. superbiens*, and their hybrids, *C. Lord Derby*, *C. Mrs. Harry Smith*, *C. A. de Laresse*, *C. Veitchii-Morgania*, *C. Youngianum*, *C. Morgania*, &c., all need the temperature of the warmest division. On the contrary, *C. Lawrenceanum*, *C. barbatum*, *C. callosum*, and their hybrids *C. Chapmanii*, *C. Maudiae*, *C. Charles Kitchman*, *C. Gowerianum*, and many others, naturally thrive and usually grow best in the intermediate house. To cultivate these plants successfully, it is essential that the receptacles be well drained, and a porous compost consisting of equal parts turfy loam, peat, and Sphagnum-moss, used as a rooting medium. The present is the most suitable time to examine the plants, and afford new material to those in need of it, as fresh growth commences soon after the flowering period is past. These plants should be given a position where they can be shaded at all seasons from strong sunshine. During the growing season there must be no lack of moisture at the roots or in the atmosphere, and those with tessellated foliage enjoy frequent overhead syringings, especially when the weather is bright.

Succulent kinds.—The dwarf-habited species such as *C. bellatulum* and its variety *album*, *C. niveum*, *C. Godefroyae* and its variety *leucochilum*, *C. concolor* and *C. Sanderae* may be classed amongst the most difficult of Orchids to cultivate, and keep in a healthy state for many years. These plants should not be grown in a warm moist atmosphere, either suspended from the roof or placed on a stage close up to the roof-glass, when they will be free from drip. Careful watering is necessary at all times, and more especially during the winter months, when only sufficient is needed to prevent the succulent leaves from shrivelling. The most suitable time for repotting is soon after the plants have ceased to flower. Disturbance at the roots, however, should not take place unless the compost and drainage make this necessary, but if the surface material is sour, pick out as much as possible without injury to the roots, and replace it with a mixture of two-thirds turfy

loam and one-third each of turfy peat and sphagnum-moss, adding plenty of finely-broken brick, or limestone, and coarse, clean sand. The hybrids derived from this section are very numerous, and while some have good constitution and grow away freely, others are difficult to cultivate, and require careful treatment.

Cooler growing species.—Plants of the late autumn and winter-flowering kinds, which occupy the cool, intermediate house, will now need liberal treatment, as these are growing freely and fast filling their pots with roots. While these *Cypripediums* are shade-loving Orchids, it is well to bear in mind that light and fresh air are necessary for the production of strong, healthy growth, from which alone can well-coloured flowers of good substance be produced. Air should be admitted by the top and bottom ventilators, whenever practicable, admitting air at night if the weather will allow.

Thus treated, there is not that flaccidness in the foliage so noticeable with those plants that are grown too warm, close, and heavily shaded. Providing the drainage is perfect, and rooting material porous, copious supplies of water will now be needed at the roots, and the plants should be kept freely syringed, to keep insect pests in check. Large root-bound specimens will benefit greatly from occasional doses of weak liquid farm-yard manure, but this should be allowed to stand until it is clear before using, for if used in a turbid state, the potting compost will become clogged and sour.

and light may have free access to all parts of the trees. After the pruning is completed, each tree should be thoroughly washed with water from the hose pipe, cleanliness being most essential to health. Stop any growths from shoots that were previously pinched back to two leaves beyond the previous stopping. Pinch out the points of all vigorous extension shoots that are making too much growth, and thus encourage the weaker ones and the development of well-balanced trees.

Gathering fruit.—The weather of late being so unsettled, it has been a difficult matter to catch the fruit in a dry enough condition for gathering. Every opportunity for this work should be seized upon and extra hands employed, so as to get the fruit gathered quickly. If necessary, spread the fruits out in ainery to dry, as another week's wet weather would completely spoil half the crop. The bad weather already experienced has caused many Strawberries to rot and the Black Currants to crack, whilst other fruits have been more or less damaged.

THE KITCHEN GARDEN.

By E. BUCKETT, Gardener to the Hon. VENERABLE GREGG, Aldenham House, Elstree, Hertfordshire.

Seakale.—The plants should now be reduced to one crown, and every care taken to encourage the building up of stout, well-ripened crowns by the autumn. Frequently stir the surface soil with the Dutch hoe; during showery weather a fortnightly application of some patent vegetable

FIG. 33.—*OOTHAMNUS ROSMARINIFOLIUS*: SHOWING DETAILS. (See text on p. 82.)

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to THE DOWAGER LADY NEWBURNHAM, WATERBURY, YORKSHIRE.

Peaches and Nectarines.—These trees should now be frequently examined and all laterals persistently pinched in at the first leaf. The fruits will require full exposure to light and air, and the leaves should therefore be fastened on one side, or, if the trees are in a very healthy condition, a few of the leaves might be removed altogether. Give trees carrying heavy crops of fruit occasional assistance by the application of liquid manure or some approved fertiliser. The best time to apply artificial manures is just before rain is expected. After the fruits have safely passed the stoning period, stimulants may be applied more freely, as the trees then require greater assistance to develop their fruits. Carefully tie in all the growths that are required for next season, removing any others in order to avoid overcrowding, and so give the trees a neat and finished appearance. The trees should be syringed thoroughly with soft water every afternoon about four or five o'clock, in order to keep them healthy and free from red spider, and occasionally spray them with weak No. 11 insecticide. The earliest varieties of Peaches such as *Amsten June*, *Alexander*, and *Waterloo*, will soon be ripening in the southern counties, and in these cases syringing of the trees and application of manures at the roots should be discontinued. The ripe fruits must be most carefully gathered, and handled as little as possible so as to prevent bruising.

Summer pruning.—All summer pruning should be brought to a close as soon as possible. Where early pinching was carried out, according to directions given in previous Calendars, little will now remain to be done, with the exception of removing any superfluous shoots which have been overlooked, so that the sun

manure specially suitable for vegetable crops, will greatly benefit the plants.

Catfishes and Chillies.—These should now be placed in cool pits or frames, fully exposed to the sunshine. Liberally supply the plants with manure water and syringe them freely in the morning and afternoon, closing the lights in good time each afternoon. Every plant should be secured to a stake.

Cucumbers.—During the next few weeks little difficulty will be experienced in procuring excellent fruits both in portable frames and cold pits, but to ensure that the plants will continue to be satisfactory until the end of September (as they certainly should) they must be kept clean and healthy. Overcrowding must be strictly avoided, never allowing the fruits to remain on the plants a day after they are ready for cutting. Prune out the old growths, stop, regulate, and peg down the young shoots twice weekly, and top-dress the roots occasionally with a compost of three parts good turfy loam and one part well decayed horse manure. Failing the latter, add a 3-inch portful of Clay's fertiliser to every half-bushel of loam. Ventilate early in the morning, but close the lights early in the afternoon, and, as the nights become cold and chilly, endeavour to create warmth with good fermenting material placed round the outside; also cover the lights with mats or other suitable material. Sow seeds singly in small 60-sized pots for raising plants to yield a supply during late autumn and early winter. Select a variety which possesses a robust constitution, and which is a prolific fruiter during the short days. For home use, and especially where a continuous supply has to be maintained, those varieties of medium length are far more profitable and frequently of better quality, particularly during the winter. Use a light compost and raise the seedlings in a brisk heat.

REPORT OF THE CONDITION OF THE OUT-DOOR FRUIT CROPS.

[FROM OUR OWN CORRESPONDENTS.]

THE WORDS "AVERAGE," "OVER," OR "UNDER," AS THE CASE MAY BE, INDICATE THE AMOUNT OF THE CROP; AND "GOOD," "VERY GOOD," OR "BAD," DENOTE THE QUALITY.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens or plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, and as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unmailed communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents. Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturalists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Appointments for August.

MONDAY, AUGUST 3—Wellington Fl. Sh. Shirley, Millbrook & Freemantle Hort. Sh.

TUESDAY, AUGUST 4—Roy. Hort. Soc. Coms. meet. Nat. Amateur Gard. Assoc. meet.

WEDNESDAY, AUGUST 5—Roy. Hort. Soc. of Ireland and Nat. Sweet Pea Soc. Sh. at Dublin.

THURSDAY, AUGUST 6—Midland Carnation Soc. Exh. at Birmingham.

WEDNESDAY, AUGUST 12—Taunton Fl. Sh. (2 days).

SATURDAY, AUGUST 15—Sandway and Dist. Fl. Sh.

TUESDAY, AUGUST 18—Roy. Hort. Soc. Coms. meet. British Gard. Assoc. Ex. Council meet. Brighton Fl. Sh. (2 days).

WEDNESDAY, AUGUST 19—Shropshire Hort. Soc. Exh. at Shrewsbury (2 days). Hemel Hempstead Fl. Sh.

THURSDAY, AUGUST 20—Roy. Hort. Soc. of Aberdeen Sh. (3 days). Oxford Autumn Fl. Sh.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—63°.

ACTUAL TEMPERATURES:—LONDON.—Wednesday, July 29 (6 P.M.): Max. 75°; Min. 57°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, July 30 (10 A.M.): Bar. 30.4; Temp. 75°; Weather—Bright sunshine.

PROVINCES.—Wednesday, July 29 (6 P.M.): Max. 71° Guildford; Min. 63° Newcastle.

The Fruit Crops.

In conformity with our usual practice, we have asked a large number of correspondents to send us reports upon the present condition of the fruit crops in their districts. The tabulated information so obligingly sent us we place before our readers in the present issue, reserving the fuller remarks for future publication.

In our review of the crops last year we said that they could not fairly be described as unsatisfactory, notwithstanding that the most important crop, that of Apples, was below the average. It will be remembered that the Apple crop was very deficient, but that Pears were less scarce, and that the outstanding features were the abundant crops of Plums, Cherries, and Apricots, and small fruits, in which term are included Gooseberries, Currants, and Raspberries. In some respects the present crops are opposite to those of last year, but in no instance is this more marked than in the case of Apricots. In 1907 the returns for Apricots were 101 above average, 62 average, and only 20 under average. This year there is not a single return from the United Kingdom or Ireland recording a crop above the average, and there are only eight reports of average crops, whilst the number who return deficient crops is 151.

It is satisfactory to find that the great fruit

crop of the year, namely, the Apple crop, is appreciably better than last year, or even than in 1906. This season there are 185 reports of average or over average crops, and 90 of crops that are less than the average. Last year there were 175 reports below average and only 114 average or above the average, whilst in 1906 there were reports of 109 average crops, 40 over the average, and 104 below the average. But whilst the Apple crop generally is satisfactory, it appears to be very deficient in Scotland, the returns of average crops from Scottish gardens being even fewer than last year.

Pears are certainly less plentiful over the whole kingdom than last year, but the returns are slightly better than in 1906. There is little to complain of in respect to Plums, for whilst there are 146 returns of under average crops, there are 126 who report crops equal to, or above the average. We cannot expect to have every year such abundant crops of Plums as were common last season, and probably most cultivators do not desire them. Such excessive crops of a soft fruit like the Plum are apt to cause the cultivator a great amount of anxiety and labour for very little return, and in any case they invariably lead to waste, because the growers neglect to provide themselves with satisfactory means of conserving the fruits upon the premises for use in the winter season or in the following year if the crops should be deficient. It is remarkable that even a good average crop of Plums should be obtained this year, because it frequently happens that immediately following a season of bountiful crops there is a period of scarcity. Cherries are somewhat less plentiful than last year, but out of 258 returns there are only 85 which indicate crops that are below the average. We have already alluded to Apricots, and it has to be said that out-of-door Peaches and Nectarines are also very deficient. In this case it must be borne in mind that the excellent crops of out-door Peaches and Nectarines were a feature last year. The crops of Currants, Raspberries, and Gooseberries, which are for convenience included in the table under "Small Fruits," are plentiful, and this remark applies with even greater force to Strawberries, for out of 278 returns there are only six which record the crop as below the average yield. We may mention, however, that many of our correspondents have excepted Gooseberries from their returns, and it may be assumed that this crop has been a scant one in many gardens.

The nut crop is not of the same importance as some of those to which we have referred,

but it may be added that nuts are almost as plentiful as they were last year.

Remembering the severe weather experienced in the last week of April, it is satisfactory to know that the fruit crops are as bountiful as our reports indicate, for many of us whilst visiting the Quinquennial Exhibition at Ghent received telegrams which described snowstorms in England of such severity as are rarely experienced even in winter. We suspect it was the weather at that time that ruined the crops of such early blooming fruits as Peaches, Nectarines, and Apricots.

Sweet Peas

Probably no garden flower is capable of creating a more beautiful and varied combination of floral colouring in any one exhibition as is the Sweet Pea. Those who were privileged to see the remarkable display made by the National Sweet Pea Society in the Horticultural Hall, Vincent Square, on the 24th ult. will be likely to admit this much at least. Looking upon the exhibition from the height of the gallery, the effect was one of exceptional beauty. Nowhere was there to be seen a harsh colour, but the softest, most delicate hues predominated, and the harmony of colouring was remarkable. A welcome deviation from the ordinary straight table monotony was furnished by Messrs. Jas. Carter & Co. in their central circular-arched stand, which was picturesquely decorated with baskets and vases of Sweet Peas. If a similar feature could have been placed at each corner of the Hall, the effect would have been even greater, but the exhibit in itself was sufficient to provide a rest for the eye upon entering the exhibition. Several of the trade firms who occupied positions next to the walls of the building had done much to display decorative effect. This was especially seen in a triumphal arch which Messrs. Felton had erected very near to the entrance to the Hall, and it was most brilliantly decked with flowers and foliage.

It is worth remark that in the competitive classes the exhibits represented a very wide range of country. There were flowers from the south-west of Cornwall and from Westmoreland, whilst every intervening county seemed to be more or less represented, as was also the Principality of Wales.

The fine flowers displayed by southern growers afforded the leading feature of the show, especially those exhibited by Sir Randal Baker, from Blandford, Dorset, by Mr. Wellesley, of Woking, in Surrey, and by Messrs. Basile and Stevenson, of Adlestone. The twelve bunches with which Mr. Wellesley won

the Henry Eckford Challenge Cup were probably equal to any that have ever been staged. This speaks volumes for the capacity of Surrey sand and a comparatively dry climate to produce superb flowers, for whilst the flowers from Wales and Ulverston seem, in their long, stout stems, to dominate over others, they appear to produce these stems rather at the expense of the flowers. Another notable fact is the tendency of flowers on long stems to develop long internodes between the flowers, thus to some extent to rob them of that effectiveness which pertains to those more compactly grown. It is clear that the straining after long stems may be carried too far. No one seems to have exhibited Sweet Peas, the produce of seed inoculated by nitro-bacterine. Our enquiries of those growers who had very fine blooms, led to entirely negative answers. Deep culture and ample manuring are old-fashioned aids to culture, but they are the methods of the best growers, and cultivators are careful also to sow the seeds thinly. If seedlings be raised under glass for flowering early, successional sowings should also be made in the open ground, to maintain the supply of flowers. A noteworthy feature of the Sweet Pea Shows is the illustration which they afford of the development of a common garden flower.

In addition to this exhibition, the Midland Sweet Pea Society held a successful show at Wolverhampton on Wednesday last, and at Dublin on the 5th inst. the National Society will hold an exhibition in connection with the annual show held under the auspices of the Royal Horticultural Society of Ireland.

OUR SUPPLEMENTARY ILLUSTRATION represents a batch of two hundred plants of seedling Gloxinias grown at Warsash House Gardens, near Southampton, the residence of G. SHENLEY, Esq. According to our correspondent, Mr. EDWIN MOLYNEUX, the plants displayed excellent culture, and we think our readers will agree with Mr. MOLYNEUX'S appreciation. The plants are luxuriant in foliage, and some of the blooms measure as much as 5 inches in diameter. At the time the photograph was taken, many of the plants were carrying 30 fully-developed blooms. All the plants were obtained from one 5s. packet of seed. The culture practised by Mr. HUNT, the skilful gardener, is as follows: The seed was sown at the end of February, 1907, in a warm, moist house, and the seedlings were potted into 60-sized pots as soon as they were large enough to handle. In these latter pots they were allowed to flower last year, and then fully exposed to the sun in a cool Peach-house, afterwards being stored for the winter on shelves in the potting shed, which is over the stokehole, and consequently calculated to thoroughly dry off the roots. Early in March they were placed in ainery which had been recently started, and as growth commenced they were transferred to jots 4 inches and 5 inches in diameter and placed in a heated pit, kept moist, and carefully watered. Here they remained until the flower stems were showing, then they were removed to a low span-roofed stove to develop their flowers. The plants were about 15 months old when the photograph was taken. For the rooting medium Mr. HUNT uses a compost of turfy loam, decayed manure, and sand. The plants are freely fed with weak guano water after the pots have become filled with roots.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held in the hall at Vincent Square, Westminster, on Tuesday, August 4th.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We are informed that GEORGE W. F. MACNAUGHTON, Esq., M.D., M.R.C.P., F.R.C.S., &c., of 33, Lower Belgrave Street, S.W., has been elected honorary physician to this Institution.

NOTES FROM THE NORTH-WEST.—SIR HERBERT MAXWELL, Bart., writing on July 22, sends us the following interesting note from Monreith, Scotland:—"The vigour of *Buddleia variabilis* is amazing, both as regards the type and its variety *Veitchii superba*. Being in full growth on April 24, it was badly cut by the severe frost of that date, all the young shoots being destroyed, and young plants killed down to the ground. The bushes set to work to repair damages at once. They have made 3 and 4 feet of fresh growth, and the remarkable part of it is that this growth is now (July 22) loaded with flower-buds, so that the display has merely been postponed a couple of months. *Buddleia globosa*, being later in starting growth, did not suffer at all, and the flower is past. *Rubus spectabilis*, which was cut as badly as *B. variabilis*, recovered as freshly, but is producing very few flowers. *R. nobilis* was uninjured by the frost, owing to its later growth in spring. This fine shrub, which I received some years ago from Glasnevin, resembles *R. spectabilis*, but flowers two months later and far more continuously, producing no suckers. The loveliest of all the blue Geraniums is *G. Wallichianum*. It has the spreading habit of *G. sanguineum*, but it continues to flower all through summer and autumn. The blossoms are about the size of a florin; the petals are sky-blue, white towards the claw, and veined with crimson. *G. platyanthum*, recently introduced from China with trumpet-flourish, is a worthless affair, hanging its dingy flower-heads as if ashamed of their inferiority to our own *G. pratense*. Thirty years ago, or thereby, I dug up in the Valtellina Alps a sturdy Composite, which has flourished in the open border ever since, growing 3 feet high, and producing large heads of a fine rose-colour, after the manner of *Centaurea macrocephala*. Hitherto I have failed to get it named; but now Professor ISAAC BAYLEY BALFOUR pronounces it to be *Centaurea Rhaiponticum* (I am not responsible for the concord). If the seed ripens well, I shall be happy to send some to any reader of the *Gardeners' Chronicle*. The plants makes a fine group with Delphinium.

Another charming companion for that fairest of Larkspurs is the Queen of the Prairie—*Spiraea lobata* or *venusta*. It passes my comprehension how anybody can be content with *S. palmata* and neglect this species, which, though equally easy, is infinitely more refined and of purer rose. The common Evening Primrose, *Oenothera biennis*, is usually classed and treated as a biennial; but with me it is more durable than many things. Within ten yards of me as I write is a plant four years old, which has grown into a great bush 6 feet high and 12 feet round, although, in the interest of its neighbours, I have cut it back severely every year. When it behaves like this it is a truly fine thing, and, were it rare and costly, would be as highly esteemed as Romneya Coulteri. A scattering of seed in any bare woodland ground, not too dry, ensures an annual display of showy, lemon-yellow blossom. Another yellow American which has established itself permanently with us is the common Monkey Flower, *Mimulus nitens*. It has escaped from cottage gardens into countless hills and brooks,

taking complete possession of their margins, and lining them, sometimes for a mile and more, with a continuous chain of gold, lasting in flower throughout June and July."

NATIONAL CARNATION AND PICOTEE SOCIETY (NORTHERN SECTION).—We are asked to remind our readers that the annual exhibition of the northern section of the National Carnation and Picotee Society will be held in the White City (late Botanical Gardens), Old Trafford, Manchester, on Saturday the 15th inst.

ROYAL HORTICULTURAL SOCIETY OF IRELAND.—We are asked to publish the following details respecting the provincial show of the National Sweet Pea Society, which will be held at the Royal University, Dublin, on Wednesday, August 5, in conjunction with the autumn show of the Royal Horticultural Society of Ireland. All Sweet Peas in competitive classes must be shown in vases provided by the National Sweet Pea Society. A charge of one penny each will be made, and application for the hire of the vases must be made to the secretary of the Royal Horticultural Society of Ireland, 5, Molesworth Street, Dublin. All the Sweet Peas exhibited must be legibly named on white cards, which will be supplied by the secretary of the Royal Horticultural Society of Ireland, and the use of any other cards will not be permitted.

A GREAT SEED HOUSE.—Under the above heading there appeared in the issue for June 27 of our contemporary *The American Florist*, of Chicago, a descriptive article concerning the famous French firm of VILMORIN, ANDRIEUX & C^{IE}. The article is illustrated by a portrait of M. PH. DE VILMORIN, and the following views of the firm's establishments, viz., the Massay seed farm, the warehouses at Paris, the warehouses at Verrières, the city store and offices, the old shop as it was half a century ago, the warehouse at Neuilly, warehouses and greenhouses at Verrières. The text of the article deals with the business aspects of the VILMORINS, a former article having been devoted to the scientific accomplishments of this illustrious horticultural family. The highest testimony that can be paid to the management of any firm is that contained in the concluding paragraph, which says:—"Clerks having had from 40 to 50 years' experience in the firm are of common occurrence, and men with 30 years of active service may be counted by the score. Many of the clerks have been employed by the firm from grandfather to grandson without a break." Eloquent but simple words these, that go a long way to explain the prosperity of the firm.

THE CARDIFF SHOW.—The annual exhibition of the Cardiff and County Horticultural Society was held on the 22nd ult., and proved very successful. A feature at this show was an excellent collection of Melons, Tomatos, and culinary Peas, contributed by Messrs. SUTTON & SONS, Reading. This exhibit was florally decorated, and thus made doubly attractive. It was awarded a Gold Medal. Messrs. ED. WEBB & SONS, Worsley, were also awarded a Gold Medal for a meritorious exhibit of vegetables, Melons, and Sweet Peas.

SWEET PEA AUTHOR HONOURED.—A short time ago Mr. G. D. CLARK, of Dover, wrote a little treatise on the culture of the Sweet Pea (*Les pois de senteur*) in the French language, and for this he has recently been awarded the Silver Medal of the National Horticultural Society of France.

FRANCO-BRITISH EXHIBITION.—We notice that our correspondent, Mr. HARMAN PAYNE, is writing a series of interesting articles on horticulture at the Franco-British Exhibition in the columns of our French contemporary *Le Jardin*, of Paris.

COURS LA REINE GREENHOUSES.—Horticultural visitors to Paris will learn with regret that the demolition of the two large greenhouses in which the National Horticultural Society of France has held its spring and autumn shows for the past eight years has definitely been decided upon. We may well enquire, with our excellent contemporary *Le Jardin*, where will the horticultural shows be held in the future?

its perusal to all who are interested in the subject. The first few lines in the author's preface give some reason for writing on the subject. He says: "A strong conviction that the recent endeavours to work up a 'milk scare' are both groundless and mischievous, has induced me to publish this pamphlet." The more important points which Sir WALTER GIBBEY sets forth in the 42 pages of his pamphlet

The tuberculin test for cows he considers to be of "very doubtful utility." The pamphlet is both interesting and instructive, as it contains a great amount of information about the milk supply not only of the United Kingdom but of other countries.

THE LAVENDER HARVEST.—The Lavender farms at Mitcham and other districts in Surrey have produced a good crop, and the harvest

FIG. 14.—*MALVASTRUM HYPOMADARUM* GROWING IN THE ROYAL BOTANIC GARDEN, EDINBURGH. THE PLANTS EXCEED 5 FEET IN HEIGHT.

* **MILK AND MILCH ANIMALS.**—We have received a copy of a pamphlet dealing mainly with the milk supply of the United Kingdom, written by that high authority Sir WALTER GIBBEY, Bart., and we recommend

* *Milk and Milch Animals*. VINTON & Co., Bream's Buildings, London.

may briefly be summarised. He agrees that every possible means should be taken to ensure the cleanliness of the milk, which should be consumed in its natural condition, without being "Pasteurised" or sterilised. He holds that tuberculosis is not communicated to man through the milk in the manner urged by some

promises to be a record one. Large bundles of Lavender are being retailed in the London streets at 2d. each.

MR. R. BROWN, for the past 94 years gardener to W. STANBURY HUNTER, Esq., of Gilling Castle, Yorkshire, is leaving Gilling in order to take up farming in Roxburghshire, Scotland.

MALVASTRUM HYPOMADARUM IN EDINBURGH.

The opportunity was taken during a recent visit to Edinburgh of examining the specimen of *Malvastrum Hypomadarum* (M. corollariaefolium) which is growing in the corridor of the plant-houses in the Royal Botanic Garden. This plant is of special interest, inasmuch as it represents the stock from which the specimen figured in the *Gardener's Chronicle* for June 20, 1908, on p. 324, was indirectly derived; and as there appear to be some features in which it nevertheless differs from the plant kindly supplied by Messrs. James Veitch & Sons for the purpose of our former illustration, we reproduce a photograph (fig. 34) of the plant which reached us through the courtesy of Prof. Bayley Balfour.

The differences, although rather striking, seem to be due mainly, if not entirely, to the different methods of cultivation adopted. The Edinburgh example is growing planted out in a bed in the corridor, and is trained up the wall, where it may attain to a height of as much as 10 feet. The internodes are longer, the leaves are less downy and also less clearly lobed than in the Veitchian plant, which was grown in a pot; but the most striking difference lay in the presence of but a single flower in the axil of each leaf, a feature which is said to be constant in the Edinburgh specimen. But the fact that the flower may be replaced by an axillary shoot which itself continues to bear single axillary flowers, explains the apparent difference, for examination of the London specimens shows that the apparent clustering of the flowers is merely due to the suppression of the internodes of an axillary floriferous shoot. This is clearly proved by the appearance and position of the small bracts which accompany the younger flowers of a cluster.

The Edinburgh plant sets fruit (see fig. 35) very freely, though it appears that artificial pollination is necessary in order that it may do so. By the kindness of the Regius Keeper, in sending the material, we are able to illustrate the fruit, which is enclosed in the persistent calyx and epicalyx.

THE ROSARY.

CULTURAL HINTS FOR AUGUST.

UNTIL the recent rains, it has been almost impossible to bud Roses effectively, but now that the conditions are more favourable, the work can be resumed. With the exception of the stocks of *R. multiflora* and *Manetti*, budding should be brought to a finish during the present month. I should like to draw attention to some of the remarks made last month on budding generally, for if these are intelligently followed there will be few failures. One point is very necessary, and that is not to shorten the shoots of the briar after budding, until it is seen that there is a good callus and that the union is completed, otherwise a considerable check will be given at the wrong moment, and weakly buds may die in consequence.

Established plants after flowering early in the month can be cut back a little, and if fed with weak liquid manure, will be capable of flowering again in the autumn; varieties of the Tea, Hybrid Tea, China, and Bourbon sections are most valuable for this purpose, the flowering shoots upon pillar and rambling roses may be shortened or cut right away as soon as the blooms have passed, in order to provide room for layering the young shoots, which are now growing too quickly from the base. The climbing Teas and Noisettes after their first flowering, are more of a perpetual character, and all that is now necessary is to shorten the old wood a little and cut out weakly and unripe growth, removing all

seed pods and spent flowers. Plants in active growth may be afforded surface mulchings of manure, and occasional applications of liquid manure.

Examine the early-budded Briars and loosen any ties that appear to be cutting into the bark, but it is too early to remove such ties altogether.

The Multiflora stock is especially valuable for the working of strong-growing varieties of climbing Noisettes, Hybrid Teas, and Ramblers. The following varieties are especially good and free climbers, whether for planting out of doors or under glass:—*Aimée Vibert*, *Alister Stella Gray*, *Climbing Niphetos*, *Belle Lyonnaise*, *Belle Siebrecht*, *Bouquet d'Or*, *Cheshunt Hybrid*, *Climbing Devonensis*, *Gloire Lyonnaise*, *Ophiric*, *Madame Alfred Carrière*, *Madame Ernest Levasseur*, *Reine Marie Henriette*, *Gloire de Dijon*, *Dorothy Perkins*, and *Kaiserin Frederick Victoria*. Insert the buds as low down as possible upon the stocks, and it may be remembered that such Roses may be budded upon the Multiflora stock as late as the end of the first week of September. If some of the early buds have failed fresh ones may be put in as near to the main stem, or the axis of the shoot as possible.

The present is a suitable time to increase the stock of any desirable variety by layering the shoots, provided the ground is in a good condition, or, failing this, it is possible to apply frequent soakings of water to thoroughly moisten the soil to the depth of one foot, keeping it in

FIG. 35. FRUITS OF MALVASTRUM HYPOMADARUM FROM THE ROYAL BOTANIC GARDEN, EDINBURGH

this condition until the layers show signs of making growth.

Shoots which have matured out-of-doors are the best for this purpose, and should be at least one foot in length. Make a sloping trench 10 inches deep and dig into the bottom a good layer of sandy grit, burnt earth and leaf-mould, for the rooting medium. Make an incision one inch long half-way through the shoot, giving it a slight twist and placing it carefully against the trench on the compost; make the shoot firm with a hooked peg, fill in the trench and level the soil, treading it firm before applying a good watering. Afford the surface of the ground a liberal mulch.

Pot Roses that were forced early and that have been placed out-of-doors should be examined for the purpose of cleansing them from all insect pests, but the rotting or top-dressing may be deterred until September. If pot plants were stopped in July for the last time they should now be cleansed from insects and mildew, preparatory to housing them in an unheated house at the end of September. If the plants have been well disbudded and properly looked after they will provide a valuable quantity of flowers during autumn.

Roses that are planted out under glass have had a hard time of it, excepting those which are cultivated in houses having movable top lights, in which cases the lights are best removed altogether during such weather as we have recently experienced. The borders should now receive a mulching of cow manure and soot, together with ground bones, applying an abundant watering

afterwards. Syringe also an insecticide into the heads of the plants by means of the garden engine, and thus thoroughly cleanse the foliage from dirt and insect pests. The most forward plants may be pruned during August, leaving only the strongest and ripest growths. Ventilate the houses to the fullest extent both night and day. Climbing and pillar varieties trained to the posts and roofs of the houses require pruning in a lesser degree, leaving in these cases the rods of this season's growth intact, but shortening the thinner and less vigorous shoots. The Hybrid Teas give the best results when planted out in borders; they flower more freely and have a more or less perpetual character. Excellent varieties include *Lady Battersea*, *La France*, *Caroline Testout*, *Duchess of Albany*, *Killarney*, *Mrs. W. J. Grant*, *Mildred Grant*, *Perle des Jardins*, *Niphetos*, *Safrano*, *Liberty*, *Madame Abel Chateau*, and *Kaiserin Augusta Victoria*.
J. D. G.

NOTES FROM A "FRENCH" GARDEN.

AT the beginning of July we removed the lights from the Melons, but owing to heavy rains we have had to replace them, leaving, however, the lights open at nights, because the Cauliflowers that are growing amongst the Melons require air both by day and night. The first batch of Melons planted at the end of March is practically exhausted, and we are taking the frames from them for the protection of other Melons planted at the end of June, which have been sheltered up to the present time by cloches. We are now planting *Endive La Ruffec* in the open ground; this batch will be ready in October. *Endive* always give excellent results at that time and are superior in quality to those cultivated earlier in the season. The last batch of *Cos Lettuce* to be sown this season has just been put in, and if the weather in autumn is very wet we shall have to shelter the plants with cloches in order to obtain satisfactory results. The consignments of horse manure for early use next season have commenced to arrive. We stack it in heaps 12 to 15 feet wide and 20 to 22 feet long, leaving three apertures in the centre of each stack for the escape of gases; care has to be taken to watch the manure, for in the event of the heat becoming excessive, the stack must be pulled down and remade, otherwise the manure will slowly smoulder away into ashes.

In the new garden, where the quantity of well-decayed manure is short, it is advisable to sow on an old manure bed some Spinach or plant some Cabbage Lettuces, but the bed may be cleared again by September, and thus be available for the sowing of Cabbages, Cauliflowers, and Lettuces. If there is no decayed manure to be obtained, all the spare time should be spent in making fine soil for these different crops. For this purpose good fine loam, mixed with half its quantity of well broken up manure, should be stacked together; the heap will have to be turned over occasionally and broken up with the back of a fork. *P. Aquatics*, *Moyland*, *Essex*.

TREES AND SHRUBS.

TRICUSPIDARIA LANCEOLATA

I HAVE had the privilege for a number of years of seeing a good specimen of this shrub in the garden of Mr. W. D. Robinson-Douglas, at Orchardton, Castle Douglas, Kirkcubrightshire, and on the occasion of a visit a few days ago, I was glad to observe that it had withstood the severe weather of the spring better than I had anticipated, although many of the flower-buds had dropped. The foliage was, however, unimpaired, and was in itself pleasing, even without the few flowers of deep crimson which nestled among it. The plant at Orchardton is on rock-work and faces almost due south-west, and is now more than 6 feet high, and about as many feet through. Orchardton lies close to the Solway, and is in a mild part of the county, but there are many places in similar districts where this fine plant might well find a place, seeing that it also thrives well on the Ayrshire and West-Lothian coast. *S. Arnott*.

STRAWBERRIES IN POTS.

HARDLY is the business of one Strawberry season over and done with than it is necessary to begin making preparations for the next. By the middle of August those who believe in making new beds in the summer rather than in the spring will be busy, but before then the plants which are to be forced next season will need to be seen to. The usual custom is to layer the first plants of the runners into small pots filled with soil, detaching them when well rooted, and transferring them into their fruiting pots before the end of September. Most people, ignorant perhaps that there is a better, if somewhat more elaborate plan of preparing Strawberries for forcing, are content to pursue the old method, but since in gardening no plan is good enough if there happens to be a better, it may be interesting to explain an improved system of preparing the plants that deserves to be more widely practised.

The first thing to do is to mark with stakes the most prolific plants on the bed from which the runners are intended to be taken. This is easily done, of course, during the fruiting season, or soon afterwards, since the fruit stems left on the plant are a good enough guide to its productivity. If, however, it is inconvenient or difficult to determine which of the plants in the old bed are the most fruitful, the selection of runners may safely be deferred till the spring. In the first case, the most prolific plants having been selected, it only remains to layer the strongest runners into pots, pinching off all the rest, and transplanting the former into a nicely-prepared bed of rich, but not recently manured, soil by the end of August. Otherwise, when the selection of runners is deferred till the spring, the strongest of the young plants will be allowed to root themselves on the old bed. So soon as the parent plants begin to bloom, it will be easy to pick out the most prolific among them and select only those runners that are attached to such plants. The runners must now be severed from their parents and transplanted carefully in moist weather, or, after a good watering, with a good ball of soil, to a new bed. At the same time every bit of bloom that the young plants are showing must be nipped off, and any subsequent blossom must be treated in similar fashion. Whether the plants have been set out in their fresh quarters in the autumn or spring matters but little if the work be carefully done, and by the time that June arrives each will be well established and making good growth. The treatment from June onwards is precisely the same in either case, the chief things to attend to being the keeping the land free from weeds, removing runners from the plants, watering in dry weather (or, better still, slight mulching) and the nipping off of all flower-buds directly they appear.

During the last week of July, or, at any rate, not later than the first week in August, the plants should be lifted and potted into their fruiting pots, which need never be larger than 6-inch (32's), the "crowns" being kept well above the soil and the roots carefully spread out while being potted, and the soil well rammed afterwards. The soil for potting should consist of two parts turfy loam, half a part of well-decayed manure, and half a part leaf-mould, with a good handful of coarse sand. After potting, the plants should be treated exactly as other Strawberries prepared for forcing.

The advantages of this system of preparing plants are many. In the first place the exclusion of all "blind" plants is assured, the presence of which adds so greatly to one's labours all through the season and deprives one of much valuable space all to no purpose. Secondly, only the very best and most fruitful plants are selected. Thirdly, the plants being in their second year, instead of mere runners, are much more vigorous and capable of carrying a heavy crop. And, fourthly, they are practically established plants by the time they are lifted into their fruiting-pots, thereby ensuring an abundance of roots—the keynote of success in Strawberry forcing. These advantages certainly compensate for any extra trouble which this more elaborate system of preparation may entail. E. S.

LAW NOTE.

LOSS OF £400 ON ORCHIDS.

At the London Bankruptcy Court recently, the first meeting of creditors was held before Mr. Savill, Official Receiver, under a receiving order made in the case of G. A. Jackson Burton, of Leighside Hall, Lewes, market gardener.

It appeared that the debtor was formerly in the Army, and afterwards in the Colonial service. He stated that he went to Lewes eight years ago, and started horticulture as a hobby; but about two years ago he began to make it more of a business. He estimated that he had incurred a loss of £300 on the purchase of Lilies, and expenditure in exploiting the same, also a loss of £400 in respect of some £900 worth of Orchids. A statement of affairs was filed, showing liabilities £9,620, of which £8,406 were expected to rank, and assets valued at £7,176, including an estimated surplus of £6,925 from securities held by creditors. The Official Receiver was informed that the liabilities were considerably under-estimated, and that the security (valued at £8,000) held by a creditor, consisting of a mortgage of the lease of Leighside Hall, and the general effects of the business, was probably much over-estimated.

Mr. Lawson Lewis, of Eastbourne, asked for an adjournment in order that an arrangement might be made for the bringing in of capital and the nursing in of the estate, with a view to the ultimate payment of a composition of 10s. in the pound.

The creditors, however, passed a resolution for bankruptcy, and appointed Mr. J. G. Fowler, chartered accountant, trustee of the estate together with a committee of inspection.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE R.H.S. EXHIBITIONS.—At the Royal Horticultural Society's Exhibitions some official pushes the exhibitors' cards amongst the exhibits, and, in many cases, they are so hidden from view that visitors are unable to see what awards have been made. A society like the R.H.S. should not leave it to the lecturer to find a chairman for his meeting from amongst the visitors assembling to hear the lecture. Surely, from the council and committees a chairman from these bodies could be elected before the day on which the meeting is to be held. John Carvill, F.R.H.S.

THE FLOWERS OF SPENSER.—I owe Canon Ellacombe an apology for my offhand and over-confident note on the word *aqueleia*. What he has written since (p. 73) makes me content to leave the derivation a still open question, though with a somewhat strong inclination to *aqueleia*. The transition of the "i" into "e"—*aqueleia*, *aqueleia*, *aqueleia*, is seemingly a strong point, but I do not feel sure that there is actual literary evidence of these forms. Scientific etymology is entirely modern, and derivations given by the early writers, from Pliny down to Linnaeus, can seldom be taken seriously. To them *aqueleia* would superficially but naturally suggest *aqueila*, and their explanations would follow suit. Linnaeus's statement has no separate value, as he simply repeats Bauhin. G. H. Englemant.

PLANTS IN FLOWER AT LEONAROSLEE.—The beautiful evergreen plant *Mitrasira coccinea* is now flowering for the second time this season, and occasionally the flowers may be found upon the plant until the end of September. It is a shrub and grows from 2 to 3 feet in height, and has bright scarlet tube-shaped flowers. The plant requires a somewhat moist position, sheltered from winds. It is very attractive in the rock-garden. Another plant in flower is *Platanus buxifolia*, a small evergreen plant, that in similar conditions succeeds very satisfactorily. It is exceedingly beautiful and perfectly hardy. The flowers, which are crimson and wax-like, resemble *Lagerflora rosea*; they continue to be produced for several months. The plant requires a certain amount of shade, but not overhead, and a little peat and good leaf-soil should be

used when planting. *Desfontainia spinosa* is a charming and beautiful Holly-like shrub, dense in habit, with opposite leaves. The flowers are axillary, and about 2 inches long. They are crimson-scarlet, tipped with yellow. The plant requires a shady and well-drained position, but there are several specimens here which succeed well in the Alpine garden exposed to sunshine. During very severe frost in winter it is advisable to cover them with heather, bracken, or similar material. *Olearia macrodonia* passed through last winter without harm, and has flowered more profusely than ever. Large plants having a diameter of 8 or 10 feet have been much admired. *Escallonia rubra* flowers with delightful freedom. It grows in any good garden soil, and may be propagated very easily from cuttings. *Cornus japonica* has presented a remarkable sight for several weeks, its large white flowers showing up to great advantage amongst such plants as *Acers* and *Arundinaria*. *Fendlera rugifolia* has also bloomed very freely. *Cissaria chinii* has been lovely. At a distance the large plants having a diameter of 6 or 8 feet had the appearance of being a snow-white cloth. *O. myrsinoides* is more rare, but it has flowered equally well. *Metrosideros floribunda* has flowered freely, and the red and the white varieties when planted together are most effective. W. A. Cook, Leonaroslee Garden, Horsham.

YELLOW-FLOWERED TREE PÆONIES.—The anticipations indulged in when *Pæonia lutea* was first introduced, namely, that it might in the hands of the hybridist give rise to a new race of Tree Pæonies, have been realised, and we may now before long hope to see some of them in our gardens. The varieties obtained by M. Louis Henry, which are referred to by Mr. W. E. Gumbleton, on p. 73, are apparently not the only ones in cultivation, for on this point I have received a most interesting communication from M. Lemoine, of Nancy, which I venture to reproduce for the benefit of the readers of the *Gardeners' Chronicle*. M. Lemoine writes: "You are probably aware that the Museum of Natural History at Paris possesses a new double yellow Tree Pæony, a cross of *Pæonia lutea*. This variety, which flowered for the first time in May, 1908, received the name *Souvenir du Professeur Maxime Cornu*. It may perhaps interest you to know that we had long ago succeeded in effecting a similar cross, and that we have a variety of no lesser merit than the plant obtained by M. Louis Henry. [We had the opportunity of seeing the latter when in bloom in May.] Our plant has the habit of a true Tree Pæony or *Pæonia Moutan*, the flowers are large, full, and of a colour which reminds one of the well-known *Rose Soleil d'Or*. It flowered this year for the third time." With M. Lemoine's long experience of propagating uncommon plants, there is great hope of this striking Pæony being put into commerce before many years. W.

XANTHORHIZA APHIFOLIA.—Amateurs who may be induced by the note in the *Gardeners' Chronicle* of July 23 to give a place in the flower border to this strange plant will be disappointed in the result, for it is far from ornamental. Interesting botanically as being the only shrubby member of the Ranunculaceae order, except the Clematis, it has not a single feature to recommend it as a decorative subject. It may serve as undergrowth in woodland, where, in a moist climate, it spreads freely and makes good game cover. At Cumloden, near Newton Stewart, there is an open wood filled with it. There is such a bewildering abundance of beautiful flowering shrubs to choose from, that there is much need of warning against planting things of indifferent merit. Herbert Maxwell, Monreith. July 25.

DWARFING STOCKS.—In the notes on Dwarfing stocks it should have been remarked that Gerarde had the Paradise Apple, though it was not used as a stock. *Mirogardenis* should be *Nurgardenis*, a variety named only by Austin. B.

FREMONTIA CALIFORNICA.—Quite recently in the gardens of East Burnham Park, the country home of Mr. H. J. Veitch, near Slough, was seen a notable example in flower of this comparatively rare deciduous flowering shrub. Originally planted at the base of a high wall, the specimen in question has long since exceeded the wall in

height, and many erect growths of some 4 feet or 5 feet in length were crowded with a profusion of the rich yellow blossoms, few, if any, appearing on that portion of the tree sheltered by the wall. At no period of the year can our garden boast of a great wealth of trees or shrubs having yellow flowers, and it would therefore appear desirable that the merits of this species in an unprotected position should be much more widely known. If one might judge from the flowering of this free-growing specimen, it would almost appear that severe pruning and training are alike unsuited to the plant, and that a better result generally might be anticipated were sheltered positions in the open selected. Nearer the coast, and generally in favoured localities, good flowering examples of *F. californica* may be seen more or less frequently, but one was not quite prepared to see a handsome tree 10 feet or 12 feet in height flowering so profusely in an inland garden. There is a wider sphere of usefulness for the *Fremontia* in our gardens than is generally supposed, and it should not be overlooked by intending planters of rare flowering trees. *E. H. Jenkins.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

JULY 21.—*Present:* E. A. Bowles, Esq., B.A., F.L.S. (in the chair), Prof. G. S. Boulger, Rev. W. Wilks, Messrs. Townsett, Hales, Worsdell, Bennett-Pot, Fraser, and Clitenden (secretary).

Floric Pansy.—Mr. HALES exhibited flowers of Pansy showing regular peloria. Many had but four petals, others had five, and each petal was spurred. Only one plant out of a batch of seedlings had exhibited this phenomenon, which appears to be very rare in the Pansy, though well known in *Linaria*, &c.

Myosotis.—Mr. BOWLES exhibited an inflorescence of the common Forget-me-not from the plant which he showed last year, and which then had the calyx much enlarged; this year, however, the calyx was of normal size.

Cypripedium with double lip.—From H. J. ALLWOOD, Esq., of Acocks Green, came a specimen of *Cypripedium Lawrenceanum*, normal in all respects except in the labellum, which was double, as though it had been cleft deeply in its very early stages of growth. This, and a curious form of *Cattleya Harrisonii*, were handed to Mr. Worsdell for further examination.

Blue Sweet Peas.—Mrs. BIFFEN, of The Gables, Histon, Cambridge, sent specimens illustrating blue forms of the "Spencer" type of Sweet Pea, together with an account of their pedigree:—

The various blue shades of waved Peas have resulted from crosses between *Zoe*, a medium blue Pea, and *Paradise*, *John Ingman*, and an unnamed rose-coloured variety practically identical with the original Countess Spencer. A similar series as far as colour goes, but less waved, has been given by a cross between *Zoe* and *Gladys Unwin*. Navy Blue crossed with *Paradise* has also given the same series, and it is probable that any shade of pink or deep rose and Navy Blue would also give them. In each case the first generation was a deep purple blue with deep blue wings. The selfed seeds from these purple hybrids (*Zoe* x *John Ingman*) gave a rather complex generation consisting of bronze purple, purple with blue purple wings, navy blue, *Zoe* blue, *Zephyr* blue, pale blue, lavender (probably Mrs. C. Foster), *John Ingman* colour, deep rose, pale rose (various shades of), tinged white. These various colours were present in both flat and waved forms, and farther as flakes on a white ground. The cultures raised were not sufficiently large to give reliable statistics, so the figures are not quoted here.

THIRD GENERATION.

The behaviour of each of the types mentioned has been traced in some detail, but attention is only called here to the blue shades. Anyone who has grown the mixtures known as Prince of Asturias, Rosie Adams,

The Marquis, Silas Cole, &c., can readily trace the genetic constitution of the heterozygous purples, whilst the pink and rose shades behaved much as the first stocks of Countess Spencer. It should be noted, though, that each of these purples can apparently be obtained in a fixed form.

The various blue shades either bred true to type or yielded a series of "sports" in definite proportions. The analysis of the whole set of statistics has not been completed yet, but the colours are given in the order of their frequency.

Zoe shade.—(1) Breaks into *Zoe*, navy, *Zephyr*, bluish pink, pale blue, and pale pink. (2) Gives the blue series just mentioned and no pinks. (3) Breeds true (*Zoe*, Countess form of), specimens exhibited).

Navy shade.—(1) Breaks into navy, *Zephyr*, and the same two pink shades as the above. (2) Gives navy and *Zephyr*. (3) Breed true (specimens exhibited).

Zephyr shade.—(1) Breaks into *Zephyr* and pale pink only. (2) Breeds true (specimens exhibited).

Pale blue.—(1) ? throws *Zephyr* (no case yet met with). (2) Breeds true (specimens exhibited).

The Spencer, the Unwin, and the flat standard types all behave in the same fashion, and what evidence has been obtained at present shows that the corresponding flaked colours give the same results. A few of the flaked types were exhibited for comparison with the whole colours. It should be noted that this is not viable in either parent. When it appears it has always acted as a simple recessive to the corresponding whole colour. Thus a deep purple flake might split into purple, blue, and pink types, but each would be flaked and no self colours would occur.

It is rather a curious fact that whilst a long series of pinks, orange, white and yellow shades are known in a fixed condition, no waved blues have yet appeared in commerce with the exception of Mrs. C. Foster. This latter is heterozygous, and may be left out of account. It would seem to point to the fact that the Spencer forms are not so readily cross fertilised by bees as is generally stated. If they were so we might fairly expect that the blue shades would be as well, or, knowing the partiality of bees for blue flowers, better represented than the pinks.

HEREFORD AND WEST OF ENGLAND ROSE.

JULY 15.—The Hereford Rose Show was held this year on the above date in the Shire Hall, Hereford, and attracted a large attendance. The hall presented a handsome appearance, the large centre tables being filled with Roses, and the Sweet Peas and Hardy cut flowers arranged against the walls, while the table decorations were very effective in the centre corridor and lower hall, where also the hall pieces, baskets of Roses, and buttonholes were exhibited.

In the class for 72 varieties, the 1st prize was won by Messrs. DICKSON & SONS with a very fine display of Roses, the 2nd prize falling to the KING'S ACRE NURSERY CO., LTD., Hereford.

The 1st prize for 36 varieties was won by the KING'S ACRE NURSERY, and the 2nd prize by Messrs. TOWNSEND & SONS.

For 24 varieties the 1st prize was won by Messrs. DICKSON & SONS, the 2nd prize by the KING'S ACRE NURSERY, and the 3rd prize by Messrs. TOWNSEND & SONS.

In the amateur classes for 24 varieties, FOLEY R. HOBBS, Esq., won the 1st prize, and CONWAY JONES, Esq., the 2nd prize, both having fine displays of Roses.

In the class for 18 varieties the best exhibit was from JARRATT W. THORPE, Esq. WILLIAM REED, Esq., won the 2nd prize.

FOLEY R. HOBBS, Esq., won the 1st prize in the class for 12 varieties (trebles) and in that for six varieties of Hybrid Teas.

In the class for 18 varieties, Captain R. KILBEE STUART won the 1st prize, and he also gained the Silver Medal for the best bloom with Helen Keller, the 2nd prize falling to H. GRAYSTONE, Esq.

In the Tea and Noisette division (nurserymen),

Mr. HENRY DREW won the 1st prize for 18 varieties, and the KING'S ACRE NURSERY the 2nd prize.

Messrs. TOWNSEND & SONS had the best exhibit of 12 Teas and Noisettes, and in a similar class reserved for amateurs, FOLEY R. HOBBS, Esq., won the 1st prize.

The Silver Medal for the best Tea or Noisette bloom was awarded to CONWAY JONES, Esq., for a "White Maman Cochet," and he also won the Silver Medal for the best H.P. bloom with an excellent specimen of "Victor Hugo."

Hardy border flowers were particularly good, and the magnificent display evoked a great deal of admiration. Two extra prizes were given.

The Sweet Pea classes were well filled, a very good 1st prize winner in the class for 18 varieties being Mrs. G. W. DAVEY, and in that for 12 varieties Mrs. G. CHILD won the chief honour.

The baskets of Roses were not quite so good as usual, but the table decorations were extremely pretty and uncommon in many cases. Miss BATTISCOMBE won the 1st prize with a table decorated with mauve Clematis and pale yellow British Roses. *F. A. S.*

BRIITISH GARDENERS' ASSOCIATION.

JULY 21.—At the last meeting of the executive council of this association, Mr. E. F. Hawes in the chair, 17 new members were elected, bringing the total up to 1,325. The solicitors were instructed to proceed with the case in which a member was entitled to £11 as wages. Grants of £2 each were made to the London and Blackburn branches to carry on propaganda work. The cases of lapsed members were considered, and it was decided to strike them off the list of members. They were comparatively few. *J. W.*

NATIONAL ROSE.

EXHIBITION AT MANCHESTER.

JULY 21.—Six shows of the National Rose Society have been held in the spacious grounds of the Royal Botanical Society during the last 28 years. The exhibits on Tuesday last were satisfactory, although the blooms generally showed the stress of weather that they had passed through during the last few days. The weather was highly satisfactory, and the competition throughout keen. The blooms generally were in fair condition, the dark varieties being admirable in colour and form.

NURSERYMEN'S CLASSES.

In the class for 36 blooms, in which the Challenge Trophy was offered, the Trophy and 1st prize were won by Mr. HUGH DICKSON, of Bedford, who staged excellent blooms of *Gustave Pigeaneau*, Mrs. S. Clark, Earl Dufferin, *Comte de Ludre*, *Caroline Testout*, *Horace Vermet*, *Hugh Dickson*, *Mildred Grant*, *Frau Karl Druschki*, *Manie*, *Chas. J. Graham*, *Mrs. Theodore Roosevelt*, and others; 2nd, Messrs. A. DICKSON & SONS, Newtownards, with many fine blooms; and Messrs. R. HARKNESS & Co. were 3rd.

For 72 blooms, distinct varieties, Mr. HUGH DICKSON was again the 1st prizewinner, having remarkable blooms of *Duke of Wellington*, *Comte du Ludre*, *Killarney*, *Ulrich Brunner*, *Vermet*, *Vermet*, *Liberty*, *Victor Hugo*, *Beauty of Waltham*, *Marquise Litta*, *J. B. Clark*, and others. Messrs. A. DICKSON & SONS again followed closely with a fine stand; Messrs. FRANK CANT & Co. were 3rd.

In the class for 24 distinct varieties, three blooms of each variety, Messrs. A. DICKSON & SONS took the lead, having many noteworthy examples; Messrs. FRANK CANT & Co. were 2nd, and Mr. HUGH DICKSON 3rd.

In a class for 36 blooms, distinct varieties, the winners were Mr. W. H. FRETtingham, Nottingham, the KING'S ACRE NURSERY CO., Hereford, and Messrs. G. & W. H. BERTH, in the order in which they are named.

Mr. W. H. FRETtingham was again to the fore in the class for six varieties, three blooms of each, having fine blooms of *Horace Vermet*, *Duchess of Bedford*, and *Lord Macartney*; Messrs. G. & W. H. BERTH and the KING'S ACRE NURSERY CO. followed in this order.

For 18 Tea or Noisette varieties, Mr. G. PRINCE was to the fore with beautiful blooms, of which the best were *Bridesmaid*, *Mrs.*

Edward Mawley, Media, Comtesse de Nadailac, and Golden Gate. The 2nd and 3rd prizes were won by Messrs. FRANK CANT & Co. and Mr. H. DREW, Longworth.

Mr. J. MATCOCK, New Headington, Oxford, won the 1st prize for 12 Tea or Noisette varieties, distinct, having bright blooms of Bridesmaid and Mrs. E. Mawley, these being particularly noteworthy.

OPEN CLASSES.

A class for 12 new Roses was strongly contested, and Messrs. FRANK CANT & Co. proved the victors. They had noteworthy blooms of the varieties William Shean and Countess Amesley. Messrs. A. DICKSON & SONS followed closely, and Messrs. BEN CANT & SONS were awarded the 3rd prize.

The best exhibit of 12 blooms of any white or yellow Rose was one from Messrs. FRANK CANT & Co., who had good blooms of White Maman Cochet. Messrs. A. DICKSON & SONS won the 2nd prize with Frau Karl Druschki; and the KING'S ACRE NURSERY Co. were 3rd with the same variety.

Mr. HUGH DICKSON had the best dozen blooms of a light pink variety in Mrs. Theodore Roosevelt. The KING'S ACRE NURSERY Co. were 2nd with the variety Mrs. J. Laing; and Messrs. FRANK CANT & Co. 3rd with Dean Hole.

Mr. HUGH DICKSON won 1st prize for a crimson variety, and showed blooms of Hugh Dickson; the KING'S ACRE NURSERY Co. were 2nd, with Alfred Colomb; and Messrs. G. & W. H. BURCH 3rd with Horace Vernet.

A class for 12 roses, containing five blooms each, was well won by Messrs. A. DICKSON & SONS, who included a vase of richly-coloured flowers of Duke of Wellington; Messrs. D. PRIOR & SONS were 2nd; and Messrs. G. & W. H. BURCH 3rd.

For 12 distinct Tea or Noisette varieties, three blooms of each, Messrs. FRANK CANT & Co. won the 1st prize.

The best exhibit of 18 distinct varieties of decorative Roses, to include not more than seven trusses of each variety, was one from Messrs. FRANK CANT & Co., in which Hiawatha, Minnehaha, Perle d'Or, and Ideal were most pleasing.

AMATEURS.

The Challenge Trophy was offered in a class for 24 blooms, distinct, and the 1st prize was secured by Mr. E. B. LINDELL, Hitchin, who staged especially good blooms of Alfred Colomb, Duchess of Bedford, Mrs. Mawley, A. K. Williams, and Mrs. J. Laing. The remaining awards went to Mr. W. BOYES and Mr. N. DENNIS, Kenilworth.

For 36 blooms, distinct, Mr. R. L. PARK led with good flowers of Horace Vernet, Victor Hugo, Mildred Grant, and Liberty; the Rev. J. H. PENBERTON being 2nd, and Mr. H. C. MACHIN 3rd.

The best exhibit of nine blooms of any one Rose, except Tea or Noisette, was one from Mr. H. DENNIS, who had well-coloured blooms of Horace Vernet.

For six blooms, distinct varieties (trebles), Mr. C. S. SPREIGHT won the 1st prize; and the same exhibitor had 1st prize for six blooms of any Rose, except Tea or Noisette, showing good blooms of Her Majesty.

There were also classes for growers of a limited number of plants, and others reserved for local cultivators.

SILVER MEDALS.

SILVER MEDALS were awarded to Mr. HUGH DICKSON for the best hybrid Tea in Lyon Rose; and for any variety other than Tea, Noisette, or hybrid Tea, the winning flower being a fine bloom of Hugh Dickson. These were in the nurseryman's section. In the amateurs' classes Mr. E. B. LINDELL was awarded a Medal for the best Tea or Noisette, showing a fine bloom of Mrs. Mawley; Mr. W. BOYES for the best hybrid Tea in a fine specimen of Mildred Grant; and Mr. H. MACHIN for any other variety than Hybrid Tea, Noisette, or Tea.

NEW ROSES.

GOLD MEDALS were awarded to Messrs. A. DICKSON & SONS for a charming crimson-coloured hybrid Tea named G. E. Waud; to Mr. HUGH DICKSON for a large pure single white flower named Simplicity; and to Messrs. B. R. CANT & Co. for white Dorothy Perkins.

NATIONAL CARNATION & PICOTEE.

JULY 22.—The annual show held at the Royal Horticultural Hall, Vincent Square, on the above date was one of the best displays of Carnations we have seen. In the competitive classes the blooms were excellent, and the trade exhibits were largely supplemented by those staged at the Royal Horticultural Society's meeting on the previous day.

Mr. W. H. PAGE, Hampton, exhibited two good seedlings (unnamed). One of these, a pink variety, was of a pretty shade, and a white variety with red stripes was also good.

Messrs. PHILLIPS & TAYLOR contributed a good group, and were also successful in some of the competitive classes.

Mr. W. SYDENHAM made a good display of border varieties, and exhibited some unnamed seedlings.

In reference to the trade exhibits which remained over from the previous day, it may be remarked that in all instances the blooms had kept well, and visitors who rarely go to the ordinary fortnight meetings had an opportunity of seeing the American varieties which are not officially recognised by the National Carnation Society.

In the competitive classes the weakest point was the groups of pot plants, there being only one competitor in each class, yet it must be said that these were both of high quality. In the class for a group occupying not less than 50 square feet, the president, MARTIN R. SMITH, Esq. (gr. C. Blick), put up a fine group of varieties of high quality.

In the class for groups to occupy 30 square feet, Mr. CHAS. TERNER, Slough, exhibited a very good group of plants, not arranged so formally as in previous years, when the flowers were all fixed out on wires.

In the classes for nine blooms of separate colours, Mr. J. DOUGLAS, Great Bookham, led the way, being first in several classes, and he was also a most successful exhibitor in other classes. Miranda secured the first prize offered for a pink variety, Amy Robsart for white, Agnes Stroll for dark red, Bedford for yellow, New Premier for scab, and Marmon for a buff self. It should be noted that this Marmon is quite distinct from Mr. Burnett's Marmon, which is now such a popular variety, and was well shown in several trade groups.

In the class for dressed blooms on cards, Mr. R. G. RUD, King's Norton, was first for 12 selfs, and also for 12 fancies.

Mr. C. H. HERBERT, Acocks Green, Birmingham, secured the 1st prize for 12 white ground Picotees, and Messrs. PHILLIPS & TAYLOR were 1st for 12 yellow ground Picotees.

In the class for bizarre or flaked Carnations, Mr. BROWN was 1st with Mrs. T. Lord, a very pretty variety, and the same exhibitor was 1st for six blooms of any white ground Picotee with good blooms of Mrs. C. Hornby.

In the class for 18 bizarres or flakes, Mr. A. R. BROWN, Birmingham, was 1st with very good blooms.

For 18 selfs, Mr. MATHIAS obtained the 1st prize for very bright blooms.

In the competition for fancy varieties, MARTIN R. SMITH, Esq., won the premier honours, and also for yellow ground and white ground varieties, Mr. BROWN and Mr. MATHIAS being good exhibitors in the same classes.

The table decoration shown by Mr. C. BLICK was very pretty. For a vase of Carnations Mr. MATHIAS was 1st with a good arrangement.

In the class for five undressed blooms (selfs) Mr. R. MARTON won the 1st prize.

It was interesting to note that there were more classes for blooms on long stems in vases, and it is evident that these exhibits appeal to the public more than those dressed and shown with the paper collars; there is little doubt but that in the near future this artificial way of showing flowers will be discontinued.

An American gentleman who visited the Society's show last year could hardly find words sufficiently condemnatory the practice of showing flowers with paper collars.

The most important groups left over from the previous day were from the following exhibitors:—Messrs. CUTBUSH & SONS had a large group arranged on the floor with some tall stands, showing above vases of good blooms beneath.

Messrs. H. Low & Co., Enfield, added some additional blooms to the display made the day before.

Mr. A. F. DUTTON, Iver, Bucks also made a good display of the American varieties.

It may be of interest to note that some of the most active supporters of the Winter Flowering Carnation Society also support the older Society.

NATIONAL SWEET PEA

JULY 24.—The eighth annual exhibition was held on the above date in the Royal Horticultural Hall, Vincent Square, Westminster. The elimination of the single vase classes was responsible for a smaller show, but their passing was not regretted, for it prevented monotony. The hall and annexes were quite full. Great interest was centred round the various challenge cups, while the stand from Messrs. CARTER & Co. (see fig. 36) attracted much attention from the visitors, as did the arch decorated by Messrs. FELTON & Co.; both exhibits formed distinctly conspicuous features. Visitors were so numerous at times as to make locomotion difficult.

SPECIAL AUDIT CLASS.

This was for fifteen bunches of Sweet Peas, distinct, to be selected from the following varieties:—King Edward VII., John Ingman, Countess Spencer, Helen Lewis, Lord Nelson, Sykes, Daisy, America, Princess of Wales, Mrs. Collier, Jeannie Gordon, Navy Blue, Mrs. W. Wright, Duke of Westminster, Black Knight, Frank Dolby, Dorothy Eckford, Sybil Eckford, Geo. Gordon, Helen Pierce, and Cecilia. The 1st prize carried the Sutton Challenge Cup and the Gold Medal of the National Sweet Pea Society—trade excluded. The cup changed hands, for Sir RANDOLPH L. BAKER, Bart. (gr. Mr. A. E. Usher), Ranston House, Blandford, was adjudged the winner in a fine competition. The flowers were large, very fine in colour, and well arranged. The varieties employed were King Edward VII., Dorothy Eckford, Mrs. Collier (very fine in colour), America, Black Knight, Navy Blue, Helen Lewis, Frank Dolby, Mrs. H. Sykes, Sybil Eckford, John Ingman, Geo. Gordon, Helen Pierce, and Countess Spencer (a grand vase). The redoubtable Mr. T. JONES, of Ruabon, proved a good 2nd, the same position he occupied last year. His best bunches were Dorothy Eckford, John Ingman, Mrs. H. Sykes, Helen Lewis, Helen Pierce, Cecilia, King Edward VII., and Daisy; long bouquet wires were pushed up the stems of the flowers, perhaps not against rule, but it is doubtful if all the exhibitors know that can manipulate their blooms in this way, and it is self-evident that the flowers can be more easily and effectively arranged if these means are employed. Last year's champion, Mr. G. Stevenson (gr. to Mr. MOCATT, Woburn Place, Adlestone) had to take 3rd place, doubtless the unfavourable weather before the show was accountable for this, while Mr. VICKERS (gr. to Mr. W. H. RAWNSLEY, Alford, Lincs.) was placed 4th.

Class 2 was for 24 bunches, distinct, and again a keen contest resulted; Mr. T. VICKERS, however, proved the victor, with a fine bold display. The varieties employed were Mrs. A. Watkins, Horace Wright, Etta Dyke, Helen Lewis, Cream Spencer, Mrs. W. Rawnsley, Duke of Westminster, John Ingman, Marbled Blue, King Edward VII., Lord Nelson, H. Eckford, A. J. Cook, Queen Alexandra, Emperor, Evelyn Hemus, James Grieve (in perfect colour), Janet Scott, America, Frank Dolby, Sybil Eckford, Evelyn Byatt, Betty and Mrs. W. Wright, Mr. J. T. TRUB, Oakbrook, Seale, Sevenoaks, was 2nd, with fine examples of Mrs. Collier, Helen Lewis, Lord Nelson, Nora Unwin, Countess Spencer and Queen Alexandra; while the 3rd position was awarded Mrs. A. J. MORRIS (gr. Mr. S. HORSFIELD, Long-shaw, Chipstead, Kent).

THE HENRY ECKFORD MEMORIAL CLASS.

Here exhibitors had a distinct surprise, for Mr. F. A. WILLESLEY (gr. Mr. W. Hopkins, Westfield, Woking, stepped in and lifted the cup at the first time of asking, no mean feat, which we remember the names of the other exhibitors in the class. It was won in no unmistakable fashion either. The twelve varieties were John Ingman, Lord Nelson, King Edward VII., Helen

Pierce, Mrs. H. Sykes, Mrs. Collier, Nora Unwin, Miss Audrey Crier, Prince of Asturias, Helen Lewis, Frank Dolby, and St. George; the whole exhibit was most pleasing and well staged. Mr. T. JONES was a good 2nd, having, as his best bunches, John Ingman, Queen Alexandra, Mrs. H. Bell, Miss Audrey Crier, Helen Lewis, Black Knight, and Etta Dyke. Mr. A. E. USHER and Mr. G. STARK, Stevenson taking the other prizes in the order named.

"HORACE WRIGHT" CHALLENGE BOWL.

This trophy is offered to draw special attention to varieties most suitable for garden decoration, and competitors must select their varieties from the following sorts:—America, Beacon, Blush Queen, Countess Spencer, Dora Breadmore, Dorothy Eckford, Flora Norton, Helen Pierce, Janet Scott, Jeannie Gordon, John Ingman, King Edward VII., Lady G. Hamilton, Mrs. W. Wright, Prince of Wales, Queen Alexandra, Romolo Pizzani and Shasta. It is necessary to win the cup three times, but not necessarily in succession. Last year Mr. A. BASILE (gr. to the Rev. T. McMURDIE, Woburn Park, Addlestone) secured the coveted trophy, and on this occasion again inscribed his name on the cup as the result of a beautiful exhibit, the varieties being Countess Spencer, Jeannie Gordon, John Ingman, Dora Breadmore, King Edward VII., Janet Scott, Helen Pierce, Dorothy Eckford, and Mrs. Walter Wright. The stems were very fine and the arrangement good. Mr. E. KEITH was in good form for 2nd place, with fine bunches of Helen Lewis, Miss Audrey Crier, Elsie Herbert and Prince of Asturias.

For six bunches distinct, to include at least three of the following sorts: The Marquis, Princess Victoria, Prince Olaf, Menie Christie, and Hannah Dale, Mr. E. BROAD (gr. Mr. W. H. PROPHET), St. Blagey, Cornwall, was 1st with good examples of John Ingman, Mrs. Harcastle, Sykes, The Marquis, Menie Christie, St. George, Prince Olaf, and Mrs. Collier. Mr. A. E. USHER was 2nd, with equally fine flowers, though lacking in richness of colour.

The class for six bunches produced an enormous competition. Mr. W. J. PROPHET won the 1st prize with George Herbert, Mrs. C. Foster, Evelyn Hemus, Lord Nelson, and Etta Dyke. Mrs. A. TIGWELL was 2nd and Mr. W. E. H. PELLIER, Abbotskerswell, 3rd.

CLASSIFICATION CLASS (OPEN).

This is a class to illustrate the colour distinctions in the Society's classification, and to bring into prominence the best varieties in the several colours. Here, Mr. A. E. USHER proved the victor. His most striking bunches were Mrs. Walter Wright, Mrs. Harcastle Sykes, America, Horace Wright, Dorothy Eckford, Frank Dolby, Black Knight, John Ingman, Helen Pierce, Jeannie Gordon, and Romolo Pizzani. Mr. CHAS. W. BREADMORE, 120, High Street, Winchester, had a nicely-arranged exhibit for 2nd prize. The most striking varieties were George Herbert, Evelyn Hemus, Lord Nelson, Countess Spencer, and Queen Alexandra, while Messrs. SALTMARSH & SON, Chelmsford, were third with a nice display.

For 24 bunches of Sweet Peas distinct there was a good entry. Mr. C. W. BREADMORE won the 1st prize with a really fine collection, which included bunches of Mrs. C. W. Breadmore, Navy Blue, Spencer, Waved Mrs. Kenyon, Helen Eckford, Mrs. H. Sykes, Helen Pierce, Kathleen MacGowan, and King Alfonso. Messrs. BAKER & SON were awarded the 2nd prize, while Messrs. G. STARK & SON, Great Ryburgh, were placed 3rd.

SWEET PEAS WITH WAVED STANDARDS.

Five classes were offered in this section to draw special attention to the varieties that have waved standards, such as Countess Spencer, Helen Lewis, and others of similar form. In Class 16, which was for 12 bunches, to include at least six of the varieties enumerated in the schedule, the 1st prize being a silver rose bowl. The prize was secured by Mr. A. E. USHER, who staged excellent examples of Evelyn Hemus, Paradise Carmine, White Paradise, Marjorie Willis, St. George, Dudley Lees, Hester, Sartorius's Queen, Helen Lewis, Lucy Hemus, Paradise Regained, and King Edward VII. Mr. T. JONES obtained the Silver Vase offered as 2nd prize, with some very choice bunches.

THE BURPEE CHALLENGE CUP.

This cup, value 15 guineas, is presented by Mr. W. Atlee Burpee, of Philadelphia, for a display of Sweet Peas arranged on a table 4 feet by 3 feet and not to exceed 3 feet in height. The class is to encourage the development of the waved or Countess Spencer type. The 1st prize was won by Mr. R. BOLTON, Carnforth, who put up a splendid exhibit, and thus secured this handsome trophy. The varieties were Tom Bolton, Countess Spencer, Evelyn Hemus, Mrs. Chas. Foster, John Ingman, Miss Audrey Crier, Nancy Perkins, The Marquis, Mrs. Harcastle Sykes, and two seedlings. Mr. SILAS COLE was 2nd, having Althorp Cream, G. C. Naud, Pink Countess Spencer, Althorp White, and Gladys Cole, while Mr. A. E. USHER was 3rd.

In the class for six bunches, to include at least one each of Burpee's White Spencer, Primrose Spencer, and Countess Spencer, the competitors staged some attractive exhibits. Mr. SILAS COLE won the 1st prize, with nine clean specimens of Silas Cole, Countess Spencer,

NON-COMPETITIVE EXHIBITS.

The exhibits of Messrs. J. CARTER & Co, who occupied a large circular space, presented a fine display of baskets, vases, &c., in all the best varieties, the effect being greatly enhanced by the Smilax, Asparagus, and other light foliage employed (see fig. 36). Displays of Sweet Peas were also exhibited by Messrs. WEBB & SONS, Wordsley (Silver-Gilt Medal); Messrs. JARMAN & Co., Chard (Silver Medal); Mr. R. SYDENHAM (Silver Medal); Mr. W. J. UNWIN (Silver-Gilt Medal); Messrs. G. and A. CLARK, LTD., Dover (Silver Medal); Messrs. HOBBISS, LTD., Dereham (Gold Medal); Messrs. DOBBIE & Co., Rothesay (Gold Medal); Messrs. G. STARK & SON, Great Ryburgh (Gold Medal); Messrs. E. W. KING & Co., Coggeshall (Gold Medal); Messrs. JONES & SONS, Shrewsbury (Large Silver Medal); Mr. W. J. GODFREY, Exmouth (Silver Medal); Mr. W. DEAL, Kelvedon (Silver Medal); Messrs. H. CANNELL & SONS, Swanley (Gold Medal); Mr. C. W. BREADMORE, Win-

FIG. 36.—EXHIBIT MADE BY MESSRS. J. CARTER AND CO AT THE LAST MEETING OF THE ROYAL HORTICULTURAL SOCIETY, AND REARRANGED FOR THE SHOW OF THE NATIONAL SWEET PEA SOCIETY.

Cream Spencer, John Ingman, Lord Althorp, and White Spencer.

For a bunch each of Burpee's White and Primrose Spencer, Mr. A. BASILE obtained the 1st prize with splendid flowers, followed by Mr. T. JONES and Mr. W. HOOKINS in the order named.

SPECIAL DIVISION FOR SMALL GROWERS.

Six classes were relegated to amateurs who do not employ a gardener regularly, and the result was pleasing.

The chief varieties judged in the smaller classes were Helen Lewis, George Herbert, Evelyn Hemus, Frank Dolby, Constance Oliver, Elsie Herbert, and Mrs. Harcastle Sykes.

FLORAL DECORATIONS.

These classes were as popular as ever, and some very effective arrangements were displayed. Miss COLE, The Vineyard, Feltham, was awarded the 1st prize for the dinner-table arrangement.

chester (Silver-Gilt Medal), Messrs. BAKERS, Wolverhampton (Gold Medal); Mr. H. ECKFORD, Wem (Large Silver Medal).

NEW VARIETIES.

The following varieties were awarded First-Class Certificates or Awards of Merit by the Floral Committee when judged in the trials at Reading College Garden, but it is convenient to append the descriptions here.

W. A. Ireland may best be described as a waved, but far superior, form of Jeannie Gordon. From Messrs. DOBBIE & Co., Rothesay. (First-Class Certificate.)

Paradise Ivory.—A light buff variety with a good waved standard. From Miss H. HEMUS, Upton-on-Severn. (Award of Merit.)

Miss Constance Oliver.—A cream and pink-coloured variety, deeper in colour than Mrs. H. Bell, a very dainty variety. From Mr. W. LUMLEY, Havant. (Award of Merit.)

George Stark.—A very fine scarlet variety, having a good, bold, erect standard, the inflorescence being of large size. From Messrs. G. STARK & SONS, Great Ryburgh. (First-Class Certificate.)

Mrs. H. Bell.—A very attractive cream-coloured flower, edged with pink; it will become very popular. From Mr. R. BOLFOX, Carnforth. (First-Class Certificate.)

NATIONAL CHRYSANTHEMUM.

JULY 27.—The annual outing of this Society took place on the above date. By special permission a party of nearly 200 visited the Royal Gardens, Frogmore. Mr. McKellar and his foreman, Mr. Edwards, conducted the party over the gardens, which happened to be just in their prime after the recent rains. The herbaceous borders received unstinted praise. Notwithstanding the heat (75° in the shade) the party walked about the gardens and greenhouses for nearly three hours. The fruit houses, stoves and greenhouses, Rose garden, fruit and kitchen garden all received the attention, and one could not but admire the excellent state in which everything was found.

Lunch was taken at Laxton's Restaurant in Windsor, and was presided over by the president of the Society, Sir Albert Rollit, supported by his Worship the Mayor of Windsor on one hand and the secretary, Mr. R. A. Witty, on the other.

Sir Albert Rollit proposed three toasts: (1) the King and Royal Family; (2) the National Chrysanthemum Society; and (3) the Mayor of Windsor.

After lunch the party proceeded by a special steamer, "La Marguerite," as far as Maidenhead, where, after a two-hours' trip, tea was served at the Dumb-Bell Restaurant. The party re-embarked at 6.30, and left Windsor for home at 8.28 p.m., bringing a glorious day to a close. J. H.

SOUTHAMPTON ROYAL HORTICULTURAL.

JULY 28.—The 10th annual exhibition of Carnations, conducted under the auspices of the above Society, was held on this date in the Pavilion of the Royal Pier, Southampton. The building was filled with a general display of flowers, there being, in addition to Carnations, groups of Sweet Peas, Roses, hardy garden flowers, &c. A notable feature was a group of *Disa grandiflora* shown by Miss RASHLEIGH, Netley Abbey, the plants being very large and magnificently flowered. Several new plants were presented for certificate: this distinction was granted to two new Sweet Peas and a yellow self Carnation. The weather was delightful, and many visitors attended the show. The number of entries in the classes for Carnations was not so large as last year, this being accounted for by these flowers being exceptionally early this season.

The classes for Carnations were open to all comers, the only restriction being that trade growers were required to show in the classes in which twelve blooms are required, there being in each section a class for twelve flowers and another for six.

Flakes and Bizarres.—In the largest class there were five exhibitors, the 1st prize being won by Mr. C. H. HERBERT, nurseryman, Acock's Green, Birmingham. He showed only slightly superior blooms to Mr. CHAS. F. THURSTON, Penn Fields, Walsleyhampton, who was placed 2nd, Mr. A. R. BROWN, Compton Nurseries, King's Norton, winning the 3rd prize. Mr. HERBERT showed Master Fred, Gordon Lewis, Meteor, J. S. Hedderley, W. Skirring, Lord Salisbury, Geo. Rudd, Arthur, Sportsman, Robert Houlgrave, Guardsman and Admiral Curzon, and these varieties were representative of those in the other exhibits. Mr. THURSTON had a magnificent bloom of Geo. Melville. The best of two exhibits in the class for six blooms was shown by Mr. JAMES FAIRLIE, Acton, London, W.

White Ground Picotees.—There were the same number of exhibits in this as in the first-mentioned class, the exhibitors being the same.

Mr. BROWN, Compton Nurseries, King's Norton, was adjudged the winner of the 1st prize with W. E. Dickson, Pride of Leyton, Fortrose Brunette (a refined bloom), Lavinia, Lady Sybil, Myra, Lucy Maud Brown, Thos. William, Lady Louisa and John Smith. Mr. THURSTON was close 2nd, and Mr. HERBERT 3rd.

There were four entrants in the class for six blooms, the 1st prize being won by Mr. FAIRLIE with good examples of Fair Maud, a seedling in the style of Amy Robsart; Little Phil, Somerhill, Grace Darling and Amy Robsart. 2nd, F. W. FLIGHT, Esq., Cornistles, Twyford (gr. Mr. W. Neville).

Yellow-ground Picotees.—Again Messrs. TAYLOR, HERBERT, MATHIAS, BROWN and THURSTON competed, but they had another rival in the firm of Messrs. PHILLIPS & TAYLOR, Bracknell, Berks., who secured the 4th prize. The 1st was won by Mr. BROWN, King's Norton, with refined blooms, all with a richly-coloured ground. 2nd, Mr. H. MATHIAS, Medhurst, Hants.

In the smaller class for six blooms, there were seven exhibitors; the best was shown by Mr. J. J. KEEN, a local grower. He showed Leonora especially well; 2nd, J. A. FORT, Esq., Kingsgate, Winchester (gr. Mr. G. Cousins).

Fancy Carnations.—Messrs. HERBERT, MATHIAS, BROWN, THURSTON, TAYLOR, and Capt. R. ALLBERT, Sherwood Mount, Kenley, were the competitors in the largest class for fancy Carnations, the four first-named winning the prizes in the order in which their names are given. There was not a great deal to choose between the whole of these exhibitors, for all were very fine. Mr. HERBERT had good blooms of Sam Weller, Iris, Eldorado, and Earl King. Mr. MATHIAS showed a very regular set, Highland Lass, Lord Steyne, and Plato being a selection of his best flowers.

In the class for six blooms, Mr. KEEN was successful in competition with five other growers, his blooms being very large and brightly coloured. He showed Elaine, Mandarin, Lord Steyne, Sam Weller, Highland Lass, and Rony Buchanan; 2nd, Mr. FAIRLIE; 3rd, Mr. FORT.

Sells.—The same competitors as in the class for twelve yellow-ground Picotees contested in this. Mr. MATHIAS winning the premier prize with an admirable dozen, three of which were seedlings, W. H. Parton, Mrs. Flight, Caraba, Miss Willmott, Daffodil, and a pink-coloured seedling being his best blooms. 2nd, Mr. THURSTON, with smaller but highly-refined blooms, especially fine being the variety named after Miss Willmott.

Seven good displays were seen in the class for six blooms of self Carnations, Mr. FAIRLIE having the best in his flowers of Mrs. M. V. Charrington, W. H. Parton, Etna, Jno. Pope, Benbow and Mrs. Flight. 2nd, Dr. A. H. BEADLES, 38, Silverdale, Sydenham.

UNDRESSED OR BORDER VARIETIES.

A class was provided for twelve distinct varieties of self-coloured or fancy Carnation or yellow-ground Picotees. The schedule called for six blooms of each variety to be arranged in vases with their own foliage. Much the best exhibit was shown by Mr. HAYWOOD MATHIAS, who had Baldur, Highland Lassie, Plato, King Solomon, Agnes Trent and others in fine form. 2nd, Mr. A. R. BROWN. There was also a similar but smaller class for six distinct varieties, the best of four exhibits being shown by H. R. TAYLOR, Esq., Oakleigh, Cheam, Surrey; 2nd, Sir R. BAKER, Bart., Ranston House, Blandford (gr. Mr. A. E. Usher).

Several classes were allotted for varieties of distinct colours. The best vase of a white variety was shown by Mr. A. R. BROWN, who had Snowdrift; the best blush or pink variety was adjudged to be Mrs. Flight, shown by F. W. FLIGHT, Esq. (gr. Mr. Neville); the best vase of a rose or salmon self Carnation was shown by H. R. TAYLOR, Esq., Oakleigh, Cheam, Surrey. This flower was adjudged the premier bloom of a Self Carnation in the section for undressed blooms. Mr. FAIRLIE won in the class for a vase of scarlet self Carnations with the variety Duke of Norfolk. The best yellow self was Cecelia, shown by Mr. A. R. BROWN, whilst Benbow, shown by Mr. FAIRLIE, secured the premier award in the class for buff or terra cotta

varieties. The best vase of a dark self Carnation was shown by Mr. A. R. BROWN, who had W. H. Parton in good form.

Mrs. W. Heriot, shown by C. A. LINZEE, Esq., Alresford (gr. Mr. R. Ransom), won the 1st prize for a yellow-ground Picotee, and the best vase of a fancy Carnation was a variety not labelled, shown by H. R. TAYLOR, Esq., Cheam.

PREMIER BLOOMS.

Bizarre: R. Houlgrave, shown by Mr. C. A. LINZEE. *Flake*: Meteor, shown by Mr. C. H. HERBERT. *Sell*: Maud Allan, a new variety, shown by Mr. TAYLOR. *Fancy*: King Solomon, shown by Mr. A. R. BROWN. *Heavy-edged white Picotee*: Lady Sybil, shown by Mr. A. R. BROWN. *Light-edged white Picotee*: Mrs. C. H. HERBERT, shown by Mr. HERBERT. *Heavy-edged yellow Picotee*: Togo, shown by Mr. MATHIAS. *Light-edged yellow Picotee*: Leonora, shown by Mr. BROWN.

NOVELTIES.

CERTIFICATES were awarded to Carnation Maud Allan, a yellow self, shown by Mr. H. R. TAYLOR; and to Sweet Peas Kathleen Macgowan, a pale blue or heliotrope variety with large waved standards, and Magnificent, a flower with reddish-orange mottling on a white ground, the white only showing near the margins of the petals. They were shown by Mr. C. W. BREADMORE, Winchester, and Mr. S. MILLER, Newport, I. of W., respectively.

NON-COMPETITIVE EXHIBITS.

Messrs. B. LADHAMS, LTD., Shirley, Southampton, filled a large table with an assortment of hardy flowers, Gallardias being especially fine. Messrs. LADHAMS also showed a separate exhibit of Roses, with Begonias, Gloxinias, and suitable foliage plants interspersed. (Silver-Gilt Medal.)

Mr. E. WILLS, Shirley, Southampton, displayed Ferns and other foliage plants, flowering plants in pots of Lillium longiflorum, and, at the entrance to the Pavilion, an assortment of decorative plants.

Mr. A. F. DUTTON, Iver, Bucks., exhibited vases of Carnations relieved with trails of Asparagus. The varieties were of the winter-flowering type, and were shown in first-class style. (Silver-Gilt Medal.)

Mr. H. BURNETT, Guernsey, showed beautiful blooms of Carnations in tall glass vases. The stems were of remarkable length and the flowers excellent in every respect. (Gold Medal.)

Messrs. PHILLIPS & TAYLOR, Bracknell, Berks., showed border Carnations in variety. (Silver Medal.)

Mr. JAMES DOUGLAS, Great Bookham, Surrey, showed a border Carnations in superb style, especially fine being The Nizam, Daffodil, Cardinal, Pasha, Harlequin, and Liberté. (Silver Medal.)

Mr. F. G. BEALING, Burgess Street, Bassett, showed a pretty exhibit of Begonias, Heliotropiums, Liliums, and other flowers in a setting of Ferns, Cocos Palms, Codiaums, &c.

Messrs. TOOGOOD & SONS, Southampton, showed 60 varieties of Sweet Peas, representative of all the best kinds in commerce. (Silver-Gilt Medal.)

Another fine display of these flowers was staged by Mr. C. BREADMORE, Winchester. (Silver-Gilt Medal.)

G. R. PICTON THWAITE, Esq., Glenlieh, The Avenue, Southampton, showed vases of Sweet Peas.

Miss RASHLEIGH, Abbey House, Netley Abbey (gr. Mr. T. Jenkins), showed a group of *Disa grandiflora*. They were magnificent plants, the largest being in 15-inch pots and carrying 50 flower-spikes each. Some of the inflorescences had as many as six large, richly-coloured blooms. (Silver-Gilt Medal.)

Mr. F. G. BEALING, Burgess Street, Bassett, showed *Celosia pyramidalis* arranged amongst Ferns.

Vases of tuberous-rooting Begonia flowers were staged by Messrs. B. R. DAVIS & SONS, Yeovil. (Silver-Gilt Medal.)

Messrs. W. H. ROGERS & SONS, LTD., Red Lodge Nurseries, Southampton, displayed excellent blooms of Roses in many varieties. (Silver-Gilt Medal.)

THE WEATHER. MARKETS.

THE FOLLOWING SUMMARY RECORD OF THE weather throughout the British Islands, for the week ending July 25, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS. The weather... Over England the week was generally very fine, almost the whole of the north and north-western districts on Saturday. In Ireland and Scotland the weather was less settled, but the rains were of a calm of little value. Thunder was heard at Monaghan on Wednesday, a thunderstorm occurred at Aspatria and Rounton on Saturday, and thunder at Dublin, while lightning was observed at Brighton.

The temperature was rather above the average over the United Kingdom generally, but slightly below it in England S.E. and the English Channel, and also in Ireland and Scotland W. The highest of the maxima were recorded on rather irregular dates between the 21st and 25th, the readings ranged from 83° in the Midland Counties, and 82° in England S.E., to 78° in Ireland N., and to 72° in Scotland N. The lowest of the minima were registered early in the week, and varied from 38° in England S.W. and 39° in Ireland N. to 46° in England E., and to 51° in the English Channel. The lowest grass temperature readings reported were 31° at Llangamath Wells and Markree Castle, 34° at Cribes and 35° at West Linton.

The mean temperature of the sea... The water was rather warmer than usual for the time of the year, but rather cooler on the coast, but cooler in most localities, than during the corresponding week in last year. The actual figures ranged from 63° at Margate, 62° at Falmouth, and about 60° at the Shipwash Lightship and Seaford to 55° and less on the Scottish coasts generally, and to 51° at Aberdeen. The rainfall was less than the average in all districts excepting Scotland, where many stations in England the week was entirely without rain.

The bright sunshine was rather in excess of the average generally, but below in Scotland N. and W., and in Ireland N. The percentage of bright sunshine was 50 in England S.W., 46 in England S.E., 45 in England S.W. to 22 in Ireland N., and to 14 in Scotland N.

THE WEATHER IN WEST HERTS.

Week ending July 29. A warm, dry and sunny week... A warm, dry and sunny week... during the daytime, for most of the nights were only about a seasonable temperature. On each day the highest reading in the thermometer screen rose to, or exceeded, 75°, and on the warmest day rose to 78°. The ground is now about 1° warmer at 2 feet deep, and about 2° warmer at 1 foot deep, than is seasonable. No rain has now fallen for 10 days, nevertheless, only a few drops of rain-water came through the 24 feet of soil in the bare soil-temperature gauge. The sun shone on an average for 8 hours a day during the week, which is 24 hours a day longer than usual at this season. Calms and light airs alone prevailed for the last eleven days. The mean amount of moisture in the air at 3 o'clock in the afternoon fell short of a seasonable quantity for each hour by 7 per cent. E.M., Barkhamsted, July 29, 1908.

COVENT GARDEN, July 29. [We cannot accept any responsibility for the unjoined reports. They are furnished to us regularly every week by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the produce, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—E.M.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices. Includes items like Lily of the Valley, Alstromera, Asters, Calla, Carnations, Mignonette, Pyrethrum, and others with prices in s.d. and s.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and their prices. Includes items like Adiantum, Asparagus, Ferns, Croton, and others with prices in s.d. and s.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various plants in pots and their prices. Includes items like Ferns, Pelargonium, and others with prices in s.d. and s.

Plants in Pots, &c.: Average Wholesale Prices (Contd.). Table listing various plants in pots and their prices, including Rhodanthe, Roses, and others.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices. Includes items like Apples, Apricots, Avocado Pears, Bananas, Cherries, and others with prices in s.d. and s.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices. Includes items like Artichokes, Beans, Broccoli, Cabbages, Carrots, Cauliflowers, Celery, and others with prices in s.d. and s.

REMARKS.—Tomatoes are coming in more plentifully. There is no improvement in the trade for vegetables. Peaches and Nectarines are very scarce, both small and large fruits, and a great demand exists for them. Grapes are a slow trade, as also are foreign and English Melons. Trade generally is moderate. E. H. K., Covent Garden Market, Wednesday, July 29, 1908.

GARDENING APPOINTMENTS.

- List of gardening appointments and services. Includes Mr. J. CRANE, Mr. J. C. ELKINS, Mr. WILLIAM KINNEAR, Mr. G. W. BELLAMY, Mr. G. B. JACKSON, Mr. E. G. RENDALL, Mr. H. J. BARNETT, Mr. THOMAS YOUNG, and Mr. H. PRESTON.

COVENT GARDEN FLOWER MARKET.

During the next few weeks trade will be very uncertain, and many salesmen will be away for holidays. To ensure supplies all orders from the provinces should be sent as early as possible.

POT PLANTS.

In flowering plants *Lilium* are prominent, and *L. longiflorum* in various sizes is very good. *L. lancifolium* is rather tall. *Fuchsias* are good, but many are from late-rooted cuttings, and though well-flowered, are small. *Marguerites* are not quite so good as usual. The yellow *Chrysanthemums* are still plentiful; some are dwarf and remarkably well-flowered. *Hydrangeas* are good, especially *H. Hortensia* and *H. paniculata*. *Spiras* from retarded stock are good, but they are not much appreciated. Most growers seem to have large quantities of *Zonal Pelargonium in flower*; they do not sell very readily. Ivy-leaved and show or decorative varieties are also plentiful. *Mignonette* is now nearly over for the season. Small *Petunias* are plentiful, but they are of uncertain quality. Some very good doubles in 4's are seen. Among *Ferocis*, *Pteris tremula* in 3's only make about the same price as those in 4's did a few years ago. *Nephrrolepis cordifolia* may be seen as low as ordinary *Pterises*, but good plants of *N. exaltata* maintain their price. Good *Adiantums* also keep up in price, but several growers have been sending plants that are not fit to grow for some time for cuttings, and these are sold at any price they will make. *Palms* very little. Good *Latanias* make better prices than those from the provinces, but good *Weddelliana* in various sizes are cheaper. *Kentias* maintain good prices, and are likely to be dearer.

CUT FLOWERS.

Supplies are now very uncertain. *Lilium longiflorum* and *L. lancifolium* of best quality have advanced in price. *Roses* now vary much in quality—some have good foliage, but in many instances midrib is apparent. *Carnations* are abundant, and though large quantities of the English border sorts are seen, the American varieties are preferred. I tried fresh cut blooms of *Ruby Castle* last week and found that they do not last half so long as blooms of Mrs. F. W. Lawton or other American varieties. Sweet Peas are now of uncertain quality, but some growers are sending in very fine blooms. It is difficult to find fine specimens of those who make the best prices must cut with long stems and avoid those flowers which are too far advanced. They should be cut before the terminal buds are fully expanded, and the stamens are over, but there are some very pretty English varieties. *Gypsophila paniculata* is seen in large wagon loads. *G. elegans* is also plentiful. *A. H., Covent Garden, Wednesday, July 29, 1908.*

APPLE COX'S ORANGE PIPPIN: *L. F.* There is no fungus disease present in the fruits, and the cracking must be attributed to weather conditions, or unsuitability of soil or aspect.

ASTERS: *F. D. & Co.* We are unable to say what is the cause of failure.

BEGONIA LEAVES: *F. Bishop.* There is no insect or fungus disease present. The spots have probably been caused by concentration of moisture on the leaves. Ventilate a little earlier in the morning and syringe the plants before the sun's rays shine upon the roof of the house.

BOOKS: *Hobart.* We know of no English work on the subject of hybridisation of particular plants.

CARNATION: *Exter.* We have failed to find any evidence of the *Helminthosporium* or other fungus disease in your plant. It appears to have failed through some cultural detail being unsuitable. The plant sent for name is *Teucrium variegatum*.

COVENT GARDEN MARKET PRICES. *H. O. B.* There is no definite system of regulating the prices in the market. All salesmen know what may be expected to arrive, but they cannot estimate the demand. When there is a fair supply prices may be started low, but if the demand is larger than usual, prices may rise. Two weeks ago, for instance, melons advanced in price late in the morning fully 6s. per dozen. In respect to foreign importations, the brokers know beforehand what is on the way, and buyers also get some information. Most importations are sold by auction, and are bought by the wholesale dealers. If it is found a few days later that further supplies may fall short, the dealers advance their prices for what they have in stock accordingly, or if they know that large supplies will arrive, they clear out at a small profit, or perhaps at a loss. In regard to *Tasmanian Apples*, the last consignment for this season arrived about a month ago, but there are still some on the market

which have been kept in cold storage; usually at the end of the season prices depreciate, but this season they have advanced. *Sturmer Pippin* is the only sort of much value on the market at the present time.

CUCUMBER: *S. C.* We frequently receive fruits with leaves growing upon them. An interesting malformation in a Cucumber was illustrated in the *Gardeners' Chronicle* for September 5, 1903, p. 170.

GARDENER'S NOTICE: *H. D.* Kindly read the reply to *De Mal Lu Tis* and *E. S. S.* in the last issue.

GRAPES AND NECTARINES: *A Constant Reader.* Both vine and Nectarine foliage are badly affected with thrips and other insect pests. Owing to the presence of these destructive agencies the leaves are not able to perform their normal functions, and consequently the fruit is ill-supported, the Grapes being shanked. The skin of the Nectarines is also much disfigured by the thrips. From information contained in your letter it is probable that the border needs to be remade and fresh vines planted. You would do well to obtain a copy of the *Book of the Grape*, by H. W. Ward, also of the *Book of Garden Pests and Plant Diseases*, by R. Hooper Pearson, both of which are obtainable at this office at the price of 2s. 9d. for the former and 2s. 10d. the latter, post free.

GRUBS IN SOIL: *S. G.* The withered specimens received appear to belong to what are known as surface caterpillars, but which we are unable to determine. The remedies you are using appear to be all that are required.—*H. W.* A species of surface caterpillar, but too withered for determination.

INFLORESCENCE OF WILD CARROT: *C. C.* It is not unusual to find a single-colour flower in otherwise white soil; resemblances of the common Carrot and similar umbelliferous plants, but we are not aware that its significance has been determined.

LARGEST EXHIBITION: *A. B. C.* The exhibition of the Shropshire Horticultural Society is certainly the largest competitive horticultural exhibition usually held in this country. The Royal Horticultural Society's Shows, held in the Temple Gardens, and Holland House, Kensington, are the largest non-competitive exhibitions.

LILIUM CANDIDUM: *R. S. I. A. D.* The common Lily disease, *Botrytis cinerea*, has killed the stems, but the fungus is not present in the bulbs. It would be wise to dust the bulbs with sulphur to kill any mycelium that may be present among the scales.

LOAM: *E. G.* Your loam may be infested with julus worms, but we are unable to find any present in the sample sent for examination. In cases where the soil contains wireworm, millipedes, or julus worms, you might try the treatment with bisulphide of carbon which was mentioned in this column last week.

MELON: *J. C.* The plants have been given too much water at the roots. This has caused the fruits to crack very slightly, upon which fungi have settled in the cracks and caused rotting.

NAMES OF PLANTS: *A. C., Boscovic.* *Carthamus tinctorius.*—*J. K., Douglis.* The flowering Ash received is *Fraxinus Ornus* (*Ornus europaea*)—*G. J. W.* 1, *Omphalodes linifolia*; 2, *Spergula* sp., too withered for identification.—*A. H.* *Cephalaria tartarica*—*H. J. P.* 1, *Lantana*, garden-raised variety; 2, *Peperomia redolens*—*J. W.* 1, *Asparagus myriocladus*; 2, *Eriobotrya japonica*—*W. K.* 1, *Linaria* (*Antirrhinum*) *vulgaris*; 2, *Agrimonia Eupatori.*—*J. H. T. W.* 1, *Fuchsia boliviana*; 2, A garden hybrid of *Fuchsia corymbiflora*; 3, *Heliotropium*, garden-raised variety.—*J. K.* We cannot undertake to name varieties of *Carnation*.—*R. H. W.* *Phaius albus*, called *Thunia alba* in gardens.—*Foseman.* 1, *Sigmatostalys radicans*; 2, *Epidendrum prismatocarpum*; 3, *Oncidium leucocentrum*; 4, *Sarcantium teretifolium*—*W. H.* *Cattleya grandiosa*; *R. M.* 1, *Cochlidia sanguinea*; 2, *Promena stapeloides*; 3, *Saccolabium curvifolium*; 4, *Selaginella umbrosa*;

5, *Pteris longifolia*; 6, *Pteris aquilina* (common Bracken), which frequently comes up from the Peat in the Orchid pots.—*J. S.* *Tradescantia virginica*.—*W. W.* *Lychnis* sp., but the flower is perished.

PEAR BEURRÉ DIEP: *G. H. T.* This variety only succeeds perfectly when cultivated in sheltered positions in favourable localities, or upon walls facing to the south or south-west in less favoured localities. We expect the fruits have cracked in your instance through adverse climatic conditions.

PELARGONIUM: *W. H. S.* The plants have been killed by a fungus present in the soil. Leaf-mould should always have a sprinkling of kaint mixed with it before being used for *Pelargoniums* and similar soft-wooded plants.

PLANE LEAVES: *W. P.* The excrescences on the leaves are small galls produced by minute insects known as *Eriophyes*.

RECORD WEIGHT OF GRAPES: *W. H., Fonthill.* The largest bunch of Grapes we have on record is the white Grape (*Trebbiano*), shown by Mr. Currot, at Edinburgh, September 16, 1875, one single bunch of which weighed as much as 26 lbs. 4 ozs. With regard to Lord Hastings Grapes shown at Shrewsbury last year the weights were not given.

ROSE LEAVES: *Amateur.* These are affected with the common mildew. Flowers of sulphur is a good remedy, if applied either as a powder or mixed with water and syringed on to the foliage. If your rosary has movable lights it would be as well to expose the plants fully to the weather during this month and the next.

ROSES: *D. A. N., Lorne.* Your Roses are attacked by a parasitic *Rose* canker. The fungus which is under observation causes an outgrowth of the parenchyma cells, which produce the cancerous tumours. Cut away all parts and burn them. Protect the plants from frost in early spring. We will name the disease as soon as our research is concluded.

TO DESTROY NETTLES AND IMPROVE THE SOIL OF A BANK: *M. W.* The most effective way of getting rid of Nettles is to fork out the roots and burn them. If this is too big a job, cut the tops off with a scythe or sickle when they are quite young. If you allow the plants to flower and seed, the trouble will be increased. Respecting the bank for flowering shrubs and herbaceous plants, the whole length should be deeply dug in early autumn and exposed to frost, &c., during winter. If the soil is shallow, fresh loam should be added in March, which time planting should be given attention.

TOMATO FRUITS: *F. E. S. & Co.* There is nothing in the fruit to explain the reason of the splitting. It is probable that it has to do with the supply of moisture and heat. If there is any fungus disease present you will observe black patches on the fruits, and possibly some disfigurement of the foliage. If either condition is noticed, and you will send us specimens we will endeavour to help you in the matter.

TOMATO LEAF: *J. H.* From the miserable specimen received it would appear the younger plant is affected with *Cladosporium fulvum*. Cut off any diseased portions and burn them. Ventilate the structure more freely, and syringe the plants with a weak dilution of the Bordeaux mixture or of potassium sulphide.—*H. N. H.* The leaf is too withered for examination.

VINE LEAVES: *E. B.* The leaves are affected with red spider, and there is also some indication of intumescence. Adopt the usual remedies for red spider and take greater care in ventilating the house and supplying moisture in the atmosphere.

COMMUNICATIONS RECEIVED.—A. B., County Clare—A. D. B.—*Jas. D.*—W. B. H.—*Enquire*—W. C.—F. J. W.—A. B.—T. B. D. & Co. (too late for present issue)—*Rev. E. S.*—*Ebel M. E.*—W. B. SMALL HOLDINGS AND ALLOTMENTS.

MR. JOHNSTON is, perhaps, a little late in the field with his book on *Small Holdings and Allotments*, but the delay is amply justified by the completeness with which the subject has been treated. Most writers who have set out to explain the complications of this branch of the law have obviously experienced considerable difficulty in deciding whether to treat the subject from the point of view of the lawyer or, alternatively, from that of the layman, and there have been some who, in attempting to make a judicious compromise between the two, have failed to give satisfaction to either class. Mr. Johnston has neatly evaded the difficulty by dealing with his subject from various stand-points in their turn. He discusses the outlook

* *Small Holdings and Allotments*. The Law relating thereto, by George Arthur Johnston, M.A., Barrister-at-Law. E. P. Dutton & Co. 16s. net.

successively from the point of view of the Government departments, the County Council, the land owner, the small holder, the tenant farmer and the labourer, following this up by a concise and lucid outline of the law itself.

We would especially direct attention to the introductory chapter, covering nearly 50 pages, in which, from these several points of view, the position created by recent legislation is discussed. In a style which is admirably clear and untechnical, the author lays bare the various difficulties which must be encountered by those who may propose to respond to the invitation put forth under the new Act. Practical warning is given to intending tenants that, when bad seasons arrive (as must inevitably be the case), they must not expect to be shown any great indulgence by the public body (i.e., the County Council), whose tenants they will become. It is further pointed out that among the qualifications needed to assure success are business ability, industry, thrift and adequate capital as well as knowledge of the soil and capacity for organisation and co-operation. There is, in fact, much to agree with in the author's dictum that "Successful farmers cannot be made by Act of Parliament, and there is much inherent talent, besides acquired knowledge, required for growing fruit, raising poultry or managing a herd of cows, as there is for painting an Academy picture."

The author has also a word of sympathy for the landlord, a portion of whose land may be compulsorily taken over by the County Council, only to find it thrown back upon his hands a few years later saddled with a claim for a host of so-called "improvements," many of which may be entirely useless to him for future purposes. Perhaps the following further extract may serve to illustrate the style of breezy common-sense in which the non-technical portion of the book is written. Commenting on the danger of undue optimism, Mr. Johnston says: "You may read in some poultry manual of the hen who is to lay 200 eggs a year, but the hen which may fall to your lot will probably fall lamentably from the high standard set for her. The sow who is to produce for your profit a fine litter, ten or twelve strong twice a year, has before now been found to be barren. It is not every cow who will give you 600 gallons of milk a year—even if you know how to extract it from her, and do you know the value of the butter that you can make from that quantity of milk? The young Apple tree, which is to be in full bearing in three years' time, has a miserable way of then only presenting you with half-a-dozen fruits. Beware how you answer the call of 'Back to the land!'"

The mind of the intending small holder is next disabused of the popular delusion that he will have to pay less than the full price for his farm, or that he will be able to obtain for his own occupation any particular plot of land that he may happen to covet. In the latter connection, we are glad to note that the author avoids a pitfall (previously pointed out in these columns) which has not always been evaded by his fellow-writers, by reminding us that the County Council cannot acquire land compulsorily unless they find themselves unable to acquire, by agreement and on reasonable terms, other land suitable for their

purpose, and, in any case, the Council has no power to acquire compulsorily land for resale to intending small holders. Expert readers may, perhaps, be interested to consider a conundrum which is thus put by the author: "Prices are, in the long run, ever controlled by supply and demand. Glass, well managed, pays, but, supposing half of the applicants for these 144,000 acres intend to devote themselves to that part of the industry, what, for instance, would be the price of Tomatos then?"

The later portions of the book should prove of considerable service to the legal practitioner; the various Acts are set out with voluminous comments and explanatory notes, and these are followed by other statutes, to which reference must necessarily be made from time to time, such as the Local Government Act, 1904, the Lands Clauses Consolidation Act, 1865, and the Land Transfer Acts of 1875 and 1903, together with the rules made thereunder. The various circulars issued by the Board of Agriculture subsequent to the Small Holdings Act, 1907, are also usefully incorporated.

The volume is one which will be read with interest as well as profit by all who, in whatever capacity, are likely to find themselves in practical touch with these matters; intending applicants for land would certainly do well to expend 10s. in the purchase of Mr. Johnston's book, before risking their limited capital. We venture to predict that this volume will come to be regarded as one of the standard works on the subject, and we are especially glad to recognise in Mr. Johnston a member of that growing band of legal writers, whose aim is to interest and instruct rather than to impress their readers with the profundity of their own knowledge or the intricacy of their subject. H. M. V.

NEW OR NOTEWORTHY PLANTS.

THE GENUS *DIPELTA*.

IN 1877 the late J. Maximowicz founded the genus *Dipelta* on specimens of a shrub collected by the Russian traveller, Dr. Iasieczki, in Shensi,

* *DIPELTA VENTRICOSA* (Hemsl.)—A speciesibus tribus hactenus descriptis differt imprimis corolla usque ad basin late infundibuliformi. *Fructus* 2-5 mm. albus, habitus foliisque. *Diospyros* specibus nonnullis simillimus, novellus puberulus; ramis novigeri graciles, recti, internodiis minus l-bis brevioribus. *Folia* opposita, exstipulata, breviter petiolata, ovata, decidua, lanceolata vel ovato-lanceolata, 6-15 cm. longa, sed saepius ceteris lo, longe caudatula-angustata, basi rotundata, margine primario remote mucronato glanduloso-denticulato, secundario serrato, parvissemine striguloso, subtus pallidiora, pro parte seces costam venaeque pilosula; venae primariae utriusque ceteris 7, lineae, albus, cr. brevisculatus, petioli graciles, longiores vix 1 cm. longi. *Radix* cr. avillares et terminalis, gracillima, 1-2 vel pluriflori, brevi sed petiolis excedentes. *Pedicelli* capillares, 1-2 cm. longi, ut bracteolae floresque minute glandulosi-pubescentes, hactenus 6 valde difformibus instructi. *Bractee* dum adsumt filiformes, 2-3 mm. longae. *Bracteolae* 2 minime infra pedicellum medium postice oppositae, 4 angulae, persistentes, iuxta ovaria basin caeteris caeteris, 2 exterioribus, inaequales, ovales vel ovatae, nirore, lobum florale et axin apicantes, et 2 int. rivas laterales, angustiores, per anthesin longius exsertas, 2-3 mm. longae ad 15 cm. longae. *Calyptrae* segmenta subaequalia, linearilanceolata, aurantia 8 mm. longa. *Corolla* tubulosa, bilobata, ceteris 3 cm. longae, extra rubra, intus pura, intus albo-aurantiaca, tubus latus, rectus, usque ad basin infundibuliformis, leviter compressus, anthe basi breviter gibbosa, postice basi bilobuliformi-lanceolato bilobata, labio superiore bilobata, lobis vix distinctis subulcratis, labio inferiore paulo longiore intus leviter bilobato trilobato, lobis leviter recurvis. *Stamina* 4, didynamia, postica 2, fere brevioribus, exteriora, glaberrima bilobuliformis corollae basi natis. *Ovarium* inferum, glanduliferum, 4-loculare; loculi 2-3-fidus, uniloculari, 2 sterilibus, ovula plura imperforata, includentes; stylus filiformis, glaber, stamina aequans. *Fructus* alycis segmentis coronatus et bracteolis accrescentibus appressis absconditus, cum bracteolis ceteris 2-5 cm. diametro. *Legit.* E. H. B.

Western China. It is nearly related to the familiar genus *Dryas* (Weigela), from which it differs in having a two-lipped corolla and four didynamous stamens, but more strikingly in the bracteoles at the base of the ovary, which are persistent and grow out, forming dry wings to the fruit, from half to three-quarters of an inch across.

three species, and in each case it is dry, like that of the Elm and that of *Dodonaea*.

Of *D. floribunda*, Maxim., there is a figure and description in the *Gardeners' Chronicle* for July 6, 1907, p. 2, by Mr. H. Spooner. It was introduced into cultivation by Mr. E. H. Wilson, who sent living roots to Messrs. Jas. Veitch & Sons in 1902 and in 1904 a supply of seeds,

namely, *D. yunnanensis*, Franchet (*Revue Horticole*, 1891, p. 246, with a figure in the text), and *D. elegans*, Batalin (*Acta Horti Petropolitani*, 1898, vol. xiv., p. 174), neither of which is, I believe, in cultivation; but both are represented in the Kew Herbarium.

Messrs. Veitch now send fresh specimens of an apparently undescribed species, collected by

Dr. Dipelta ventricosa
29. 2. 1908.

FIG. 37.—*DIPELTA VENTRICOSA*.

A, barren branch of *Dipelta ventricosa*, Hemsl.; B, flowering-branch of the same; C, flower-bud, entire and in section, magn. 2 diam.; D, section of an expanded flower, magn. 2 diam.; E and F, fruit subtended by bracteoles; G, pollen, magn. 300 diam.

With reference to the fruit, Maximowicz must have described it from the notes of the collector, which, in part at least, referred to that of some other plant. The fruit, he says, "is said to be a red, edible berry." We have now fruit of

gathered on Wa Shan, at an elevation of about 4,800 feet. There are specimens of this species in the Kew Herbarium collected at Patung, Hupeh, at an elevation of 3,000 feet. Two other species of *Dipelta* have since been described,

Mr. E. H. Wilson, for which I propose the name *ventricosa*,* as it differs from the other three species mentioned, in having a corolla which is broadly inflated to the base. The name *Dipelta* was given in allusion to the large, shield-

like petlate bracteoles of the original species; but in *D. yunnanensis* and *D. ventricosa* the corresponding bracteoles are ear-shaped and attached by the margin. All the species are very similar in habit and foliage, but there are fruiting specimens in the Kew Herbarium, collected by Dr. A. Henry, 6,558, and Mr. Wilson, 268, which the former describes as a tree 10 to 40 feet high, whereas Wilson gives it the same number as his fruiting specimens of *D. floribunda*.

D. ventricosa is a shrub 7 to 15 feet high, with long, straight, slender-flowering branches, and opposite, thin, ovate leaves, mostly 3 to 5 inches long, tapering into a very slender tip. The flowers are solitary or geminate in the axils of the leaves, or in clusters of three to seven at the tips of short branches. They are borne on exceedingly slender stalks, and the larger clusters are only about half as long as the leaves; they are very pretty, but I am not in a position to say what the effect of a full-grown plant is in flower. The individual corollas are about 1 1/2 in. long, and they are two-lipped, with a broad, bulging tube, purple-red outside, and white, with bright orange markings on the lower face of the inside. Mr. Wilson collected it at an elevation of 8,400 feet. *W. Botting Hemslay.*

VEGETABLES.

CARROTS

It is a good plan to make at least two sowings of horned Carrots during July and early August for a supply of young roots during the spring months. The seeds should be sown on land with a south aspect that has been recently cleared of early Potatoes or some other spring crop. The land should be forked, and, if the soil is dry, made moderately firm, by treading. Draw the drills at 10 inches apart, an inch deep, and fully 6 inches wide, so that good broad rows may be had, thus may the plants be protected during the winter months should the weather prove severe. I have for many years adopted this method of growing spring Carrots, and have obtained small, tender, useful roots at a time when Carrots have been in demand. During very cold weather, the rows need covering over with coal ashes, leaf-mould, or some sandy soil to save the tiny roots from injury. Useful varieties for this crop are Early Nantes, Early Short Horn, and Sutton's Champion Horn. In spring, when growth has commenced afresh, the supply of roots may be prolonged by digging them up and placing them in trenches on a cool north border. In this way I have kept them in a sweet and crisp condition for several weeks, and almost till the ordinary early crop was ready.

SUTTON'S HARDY SPROUTING KALE

Amongst Kales grown in these gardens last winter, I had none to equal the above-named variety. For hardiness and productiveness I consider it one of the finest of all Kales, and it should be extensively planted where the demand for winter vegetables is extensive. Last year many of our Kales were killed by frost, also Broccoli and other winter greens, but in a large breadth not one plant of the Kale under notice was killed. The plants are of sturdy habit; the sprouts large, and these are produced in abundance from the bottom to the top of the stem. When cooked, this variety is very tender and of delicious flavour.

CELERY

Cutbush's dwarf solid red Celery is a very useful, sturdy Celery of good, edible qualities, being sweet and crisp. If planted not too early, the stalks remain firm till late in the spring. The variety suits our soil admirably.

Dwarf Crystal White is another excellent variety. I have grown this kind for several seasons. Formerly I grew the old Sandringham White, which I have discarded. *H. Markham, Wrotham Park Gardens.*

FLOWERS OF SPENSER.

(Continued from p. 65.)

MAPLE.

1. The Maple seldom inward sound.
F.O., I. i. 9.
2. Her wrinkled skin as tough as Maple rind.
F.O., I. viii. 47.
3. A mazer wrought of the maple warre.
Shepherds Calendar, August.

Spenser must have been well acquainted with the Maple of English hedgerows, so I do not understand why he should have given it the bad character of "seldom inward sound." All writers from the Romans to Evelyn praise its beautiful hard grain, so well fitted for turning, and in his day and before the wood was sought after for mazer bowls as in the third quotation.

MARIGOLD.

1. The Marigolde and cheerful Rosemarie.
Virgils Gnat, 54.
2. Faire Marigoldes, and bees-alluring Thyme.
Maiopalmos.

The name was applied to many yellow flowers, but especially to those which were supposed always to have their flowers open to the sun, hence called *solssequium* or *grasool*.

MARJORAM

Sweet Marjoram and Daisies decking Pryme.
Maiopalmos.

The wild British Marjoram was a favourite plant in the herb gardens of Spenser's time, and was a special favourite of the poets, who compared ladies "with margerom gentle, the flower of goodwillhead" (Skelton).

MOLY.

And sweet is Moly but his root is ill.
Amoretti, xxvi.

Moly is the Onion or Leek. Spenser got the name from Homer, but his description is scarcely true. No part of the Onion or Leek can be described as sweet, except that the flowers are so in a few South European species, of which certainly Spenser had no knowledge.

MULBERRY.

With love-juice stamed the Mulberry,
The fruit that dewes the poets braine.
An Elegie, 3.

The Mulberry was introduced into England from the South of France long before Spenser's time, but it was not a common tree in gardens. Shakespeare tells us (in *Mid. N.D.*) that love-juice was a drop from some flower squeezed into the eye to ensure constancy in love. Spenser probably gave this character to the Mulberry from its mention by Ovid in the story of Pyramus and Thisbe.

MYRTLE.

1. Beside the same a dainty place there lay,
Planted with myrtle trees, and laurels greene.
F.O., III. v. 40.
2. Right in the midst of the Paradise
There stood a stately Mount on whose proud top
A gloomy grove of myrtle trees did rise.
F.O., III. vi. 45.
3. Next did the Myrtle tree to her approach,
Not yet unmindful of her olde reproach.
Virgils Gnat, 28.
4. The Spartan Myrtle whence sweet gumb does flowe.
Virgils Gnat, 84.
5. Compare with Myrtle and the Bay.
An Elegie, 18.
6. The woode with Paphian myrtles peopled.
Britains Ida, II. 2.
7. While some cool myrtle shade did entertain him.
Britains Ida, V. 1.

The Myrtle, though abundant in Southern Europe, was very little grown in English gardens in Spenser's time, and his knowledge of it seems to have entirely come from the Greek and Latin authors only.

NARCISSUS.

Foolish Narcisse that likes the watry shore.
F.O., III. vi. 45.
(See Daffodils.)

NUT.

1. And gather nuttes to make the Christmas games.
Shepherds Calendar, December.
 2. Sweet is the Nut, but bitter in his pill.
Amoretti 26.
- (See Filbert and Hazel.)

OAK

1. The builder Oak, sole King of forests all.
F.O., I. i. 8.
2. Upon a snaggy Oke.
F.O., I. viii. 10.
3. As hoary frost with spangles doth attire
The mossy branches of an Oke halfe dead.
F.O., I. x. 48.
4. But she no more was moved with that might
Than it had lighted on an aged Oke.
F.O., III. vii. 41.
5. Like an old Oke whose pith and sap is scare,
At puff of every storme doth stagger here
and there.
F.O., IV. iii. 9.
6. With oaken leaves atrapt,
F.O., IV. iv. 30.
7. And in his hand a tall young Oke he bare.
F.O., IV. vii. 7.
8. As when the flashing Levin haps to light
Upon two stubborn Oakes.
F.O., V. vi. 40.
9. How often have I scaled the craggie Oke
All to dislodge the Raven of her nest.
Shepherds Calendar, December.
10. And his high head
He with an Oaken girldon now doth tire.
F.O., VII. vii. 11.
11. Whom als accompanied the Oke . . .
The Oke, whose acornes were our foode,
before
That Ceres seede of mortal men were knowne.
Virgils Gnat, 26.
12. Th' Okes deep grounded in the earthly molde.
Virgils Gnat 57.
13. The durefall Oake, whose sap is not drede,
Is long ere it conceive the kindling fyre.
Amoretti, vi.
14. The ske-bred Eagle, roiall bird
Perch there upon an Oke above.
An Elegie, 31.
15. He that hath seen a great Oke drie and dead
Lifting to Heaven her aged horie head
Who such an Oke hath seeme, let him record.
Ruines of Rome, 28.

The oak is the recognised symbol of strength and endurance, and as such it is used by Spenser; and there is nothing in any of the passages quoted to show that he had any appreciation of its beauty.

OATS.

1. The Romish Tityrus, I heare,
Through his Mæneas left his oaten reele,
Whereon he erst had taught his flocks to feede,
And laboured lands to yield the timely eare.
Shepherds Calendar, 1, October.
2. be thou deigne to heare
Rude ditties, tuned to shepherdes oaten reede.
Shepherds Calendar, December.

OLIVE.

1. The fruitful Olive.
F.O., I. i. 9.
2. Do worship her as Queene with olive girldon crownd.
F.O., I. vi. 15.
3. Like that sacred Hill, whose head full he,
Abord with fruitfull Olives all around.
F.O., I. v. 51.
4. She winnes an Olive Girldon for her nice 18.
F.O., II. ii. 31.
5. And both were with one Olive garland crownd.
F.O., IV. iii. 41.
6. And for her girldon olive branches beate.
Shepherds Calendar, November.

7. Chloris, that is the chiefest nymph of all of Olive branches, beares a Coronall; Olives bene for peace, When warres do successe.

Shepherds Calendar, April.

8. His left the palme tree stout His right hand did the peacefull Olive wild And head with Lawrell garisht was about, Sudden both Palme and Olive fell away.

Visions of Bellay, 9.

9. She smote the ground, the which straight forth the did yield A fruitful Olive tree with berries spredd, That all the Gods admired; then all the storie She compact with a wreath of Olives boarie.

Muioptomos.

It is very doubtful if the Olive was grown in England in Spenser's day, but it may have been grown as a curiosity in a few gardens, and so he may have seen it; but his accounts are all founded on his knowledge of the tree in the Latin and Greek writers and in the Bible.

ORIGANE.

Bathing herself in origane and thyme.

F.O., T. II. 40.

Origane is the Anglicised form of *Origanum*, a name that was given to many plants, but chiefly to the wild Marjoram. (See Marjoram.)

ORPEN.

Cool Violets, and Orpine growing still.

Muioptomos.

Orpen is the old name for our House-leek or Stonecrop. Spenser's "growing still" is shown in its other names, Sengreen and Livlong.

PALM.

1. There he, Lord of himselfe, with palm bedight,

His looser locks doth wrap in wreath of vine.

Virgils Gnat, 15.

2 For first the high Palme-trees with branches faire,

Out of the lowly vallies did arise,

And high shoopt up their heads into the skyes.

Virgils Gnat, 24.

3 His left the Palme tree stout His right hand did the peacefull Olive wild Sudden both Palme and Olive fell away.

Visions of Bellay, 9.

4 The Palme that monarchs do obtaine.

An Elegie, 51.

In these passages two different plants are named. In the first the Palm named is the Willow tree, of which the catkins were commonly called Palme in Spenser's time, and were used in the decoration of churches on Palm Sunday. Spenser could have known nothing of the true Palm except what he had seen of it in pictures, or read of it in books, especially, perhaps, the Bible. It was not introduced into England as a living tree till long after his time.

PANSY.

1. Fragrant Violets and Pannes trim

F.O., III. i. 30.

2. The one a Pounce, the other a sweet broct.

F.O., III. xi. 37.

3. The pretie Pounce and the Chevisaune

Shepherds Calendar, April.

Pounce is the old variant for Pansy, and the name seems to have been applied both to the wild species and to the garden varieties.

PEAR.

He him caught upon a day

Entangled in a fowling net,

Which he for carrion Crows had set

That in our Peare-trees haunted.

Shepherds Calendar, Mar.

—H. N. Ellacombe.

(To be continued.)

BERLIN HORTICULTURAL EXHIBITION.

THE preliminary programme for the great international horticultural exhibition to be held in Berlin under the auspices of the Society for the Promotion of Horticulture in the Royal Prussian States, has just been issued. The show will be held in the Exhibition Halls, Zoological Gardens, from April 2 to 13, 1909, under the patronage of the Emperor. His Excellency von Arnim-Crieven, Minister of Agriculture, is the honorary chairman. In order to give the design of the exhibition a coherent character, the Horticultural Society has instituted a public competition for the best scheme relative to the combined structure. It has been determined that the exhibits of horticultural products shall not be placed in ordinary rows or groups, but an attempt will be made "to show by small, self-contained, impressive, and decorative pictures what striking paintings, views, and landscapes" can result from a harmonious combination of horticulture and art. It is specially hoped there may be obtained for the decorative division representations of some parts of house and roof gardens, decorations of verandas and balconies, decorations for particular occasions, a decorative arrangement of ordinary market plants, &c. Horticultural implements and appliances not yet on the market or which have been placed on the market since the year 1906 will be included in the division for novelties. The programme con-

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, ante, pp. 84-90.)

0. SCOTLAND, N.

ORKNEYS.—The reason Apples and Pears are under average is the prolonged period of wet weather which prevailed whilst the trees were in bloom, and a poor set of fruit. Other fruits are suffering from drought at present and cold north-east and east winds. *William Liddell, Balfeur Castle Gardens, via Kirkcuball, N.B.*

1. SCOTLAND, E.

ABERDEENSHIRE.—I have never seen Apples a worse crop than this season, and Gooseberries are scarce. Strawberries, Raspberries, and Black Currants, however, are very plentiful. *James Grant, Rothiemorman Gardens.*

—The hardy fruit crops in this district are promising, with the exception of Plums and Pears. Plums are almost a failure, excepting the variety Victoria. Apples will be an average crop. The bullfinches and sparrows were very troublesome early in the spring. *John Brown, Delgaty Castle Gardens, Turriff.*

BERWICKSHIRE.—Fruit crops here are decidedly good, and rain has come just at an opportune time. *J. R. Redpath, Castle Gardens, Duns.*

EAST LOTHIAN.—Of Peaches, Apricots, Gooseberries, and other small fruits in many gardens here there are practically none. Apples, Pears, Cherries, and Plums are not quite failures, but, as a crop, each is very poor. Strawberries, on the contrary, are abundant and fine. The failure of fruit is undoubtedly due to the intense frosts and cold winds in the third week of April. *R. P. Brotherton, Tynninghame, Prestonkirk.*

—The irregularity of the fruit crop in this district may be said to be mainly due to the severe frost we had on the morning of April 25, when the thermometer registered 16° of frost. At that time Peaches, Nectarines, early Pears, Gooseberries, Red and Black Currants were in flower, and many were destroyed. Although Apricots had already set, they were frosted, and Raspberries and some early Strawberries suffered. Late varieties of Pears, Gooseberries, and Currants are very fine, and the Strawberry crop has been a splendid one. The Apple crop suffered to some extent from the frost, for, although not in flower, the centre of the flower-truss was frosted, leaving only one or two flowers on each truss, which, where they have set well, is quite sufficient to form an average crop. *Wm. Galloway, Gosford Gardens, Longniddry.*

FIFEHIRE.—Seventeen degrees of frost on April 24, and the badly-ripened wood of last season account for the failure of hardy fruit crops this year. *W. Henderson, Balbirnie Gardens, Markinch.*

FORKSHIRE.—Most of the fruit trees and bushes showed an abundance of blossom; but, owing to unfavourable weather, they did not set so well as their appearance when in flower seemed to promise. The very low temperatures in April ruined some of the bush fruits, particularly Gooseberries in some gardens; but in most gardens in this district, they are quite an average crop. *Thos. Wilson, Glamis Castle Gardens.*

KINCARDINESHIRE.—Owing to excessive rain and lack of sunshine in 1907, the wood of most wall trees did not ripen properly, consequently the blossom came rather weak, and that, coupled with 20° of frost about the middle of April, completed the destruction. *John M. Brown, Blackhall Castle Gardens, Banchory.*

MIDLOTHIAN.—Apricots and Peaches are complete failures, owing to the severe frosts that occurred when the trees were in bloom. We applied protection, but 18° of frost is difficult to exclude. Gooseberries are a heavy crop, although in many gardens in this district they are nearly a failure. *Wm. G. Pirie, Dalhousie Castle Gardens, Bonnyrigg.*

—The fall of snow and 14° frost in the last week of April destroyed the stone fruits then in flower, and even the crop of Peaches in the glass case, unprovided with artificial heat, was

FIG 38.—MAIN ENTRANCE TO THE EXHIBITION HALLS IN BERLIN

tains 725 competitions for hot-house plants, greenhouse plants, Conifers, Ferns, Palms, Orchids, forced decorative shrubs, Azaleas and Rhododendrons, Roses, bulbous and tuberiferous plants, Cactuses and succulents, water plants, cut flowers, hardy herbaceous plants, exhibits illustrating the art of binding, pomology or culture of fruits, vegetable culture, marketing of fruits and vegetables, nursery stock, and industrial products.

All enquiries respecting the exhibition should be addressed to the General Secretary's office, Berlin, N. 4, Invalidenstrasse 42

CULTURAL MEMORANDA.

GRAFTING ARALIA VEITCHII.

THOSE persons who are not already aware of the fact, may be interested to learn that Panax Victoria makes a suitable stock for grafting *Aralia Veitchii* and similar species. As is well known, this Panax is easily propagated from cuttings. In using it as a stock for *Aralias* the union should be made close down to the roots, for if made higher a disfigurement would result, from the fact of the stock swelling more freely than the scion. *T. Coomber*

partially destroyed. Pears and Apples are disappointing crops, notwithstanding the trees showed abundant blossom. In a succession of bad fruit seasons this is one of the worst. *James Whytock, Dalkeith Gardens.*

PERTHSHIRE.—The Apple crop in this district

DUMFRIESHIRE.—Only five out of 32 varieties of Apples are in bearing, and these have average crops. They are Bramley's Seedling, Duchess of Oldenburgh, Lord Grosvenor, Pearsgood's Nonsuch and Tower of Glamis. Strawberries are a large crop, and the fruit is of excellent

end of April. Gooseberries and Raspberries are average crops. *Thomas Lunt, Ardgowan Garden, Inverkip.*

STIRLINGSHIRE.—With the exception of small fruits, the crops have been very disappointing. There was a fine show of blossom on all trees, but all set badly. Small fruits are plentiful and of good quality. Strawberries are excellent, with large fruits of superior quality. Our soil is heavy and rich. *Henry Henderson, Bantaskin, Falkirk.*

WIGTONSHIRE.—The fruit crops throughout are disappointing. Apples, Pears, and Plums are below the average. Cherries are very poor. Peaches, Nectarines, Apricots, and Figs almost failures. Strawberries are very good, likewise Red and White Currants, also Raspberries. Black Currants are not more than half the usual crop. *James Day, Galloway House, Gartleston.*

—The trees promised well in April, but on April 24 and 25 we had 16° of frost on each morning. On June 12 we had 1° of frost. *John Brydon, Dunragit Gardens, Dunragit.*

2, ENGLAND, N.E.

DURHAM.—Apples and Pears are about an average quantity. The trees are free from blight, and the foliage is clean of all insect pests. The trees are making good growths, although the season has been very dry. *R. Draper, Seaham Hall, Seaham Harbour.*

—The fruit crop is probably the worst in seven years. Apples and Pears are much below the average and are of poor quality. Small fruits are better, particularly Strawberries, which are good; but quantities have been lost through damp caused by thunderstorms. The cause of failure in Apples and Pears I attribute to a sunless autumn and badly-ripened wood. Sharp frosts were almost nightly occurrences when the trees were in bloom; these, together with cold winds, had much to do with the failure of our fruit crops. *James Macfar, Smelt House Gardens, Howden-le-Wear.*

YORKSHIRE.—Considering the dull, wet summer of 1907, there was more blossom on Apples, Pears, and Plums than one expected. Fortunately the cold, wet April of this year kept it back, hence, with some varieties of Apples and Plums, there are very fair crops. Apples Keswick Codlin, Cockpit, Ecklinville, and King of the Pippins are excellent. An orchard of Vic-

FIG. 39.—EXHIBITION HALLS, BERLIN; VIEW OF THE INTERIOR OF HALL NO. I. (See text on p. 104.)

is a complete failure, the blossom buds being all destroyed with frost in April. Gooseberries, being in flower at the time, were also destroyed. Fruit trees and bushes in general are all very healthy at the present time in this district. *J. Farquharson, The Gardens, Kinfauns Castle.*

—All small fruits are good in quality and crop, except Black Currants, which are scarce, owing to the severe frost in the third week of April, when we registered in three nights 10°, 15°, and 16° of frost respectively. Wall fruit is also scarce. Plums and Cherries set fairly well, but have dropped badly since. Apples and Pears are exceptionally few. Strawberries are a good crop, and have ripened ten days earlier this year than usual. *T. Lunt, Keir Gardens, Dunblane.*

6, SCOTLAND, W.

ARGYLLSHIRE.—The excessively severe weather in the last week of April severely injured Pear and Plum blossom. Black Currants also suffered badly, and many of the flowers dropped. Red and White Currants are plentiful, and good; Strawberries are excellent in quantity and quality, and Gooseberries abundant. Sweet and Morello Cherries have cropped well. *D. S. Mettelle, Pottalloch Gardens, Lochgilphead.*

AYRSHIRE.—The severe frost at the end of April destroyed nearly all Plum blossom and much of the Gooseberry and Currant blossom also. Apples and Pears did not set well, although there was abundance of bloom. *William Priest, Eglinton Gardens, Kilwinning.*

—All kinds of fruit promised well here in the early part of the season, and any failure is due to the severe frosts of April 24 and 25, when 14° and 15° of frost were registered on the respective mornings. Insects were troublesome for a time, but, with the use of insecticides and the assistance of the recent heavy rains, fruit trees and bushes are now clean and healthy. *D. Buchanan, Bargany Gardens, Dailly.*

DUMBERTONSHIRE.—On April 24 and 25 we registered 14° of frost, which considerably injured all early fruit crops, especially that of Raspberries. *D. Stewart, Knockderry Castle Gardens, Cove.*

flavour. *John Urquhart, Hoddon Castle Gardens, Ecclefechan.*

—On bush trees Apples and Pears are almost total failures. On wall trees the crop is light, but the fruits good. Gooseberries are a heavy crop, but Currants are only a fair average, especially Black Currants. Raspberries have cropped well; they never fail here. Plums are but moderate, whilst Cherries are an average crop. *Jas. McDonald, Dryfeholme Gardens, Lockerbie.*

KIRKCUDBRIGHTSHIRE.—In this district Gooseberries, Red Currants, Black Currants, and

FIG. 40.—GENERAL VIEW OF THE EXHIBITION HALLS, BERLIN. THE ROOFED AREA ADAPTED FOR EXHIBITION PURPOSES IS UPWARDS OF 12,000 SQUARE METRES. (See text on p. 104.)

Strawberries are very good crops, considering the 26° of frost which was experienced on April 26. Apples and Pears are much below the average. *Wm. Skinner, Glentworth Gardens, New Galloway.*

RENFREWSHIRE.—Black and Red Currants were very much injured with frost at the latter

part. Plums close here, which cropped heavily last year, is again full of fruit. Some standard trees of Jargonelle and Hesse Pears are also well cropped. Strawberries are the fruit crop of the year, heavy crops being the rule all round. Most of the market growers stick to Sir Joseph Paxton

as their main crop, although several of them have tried some of the newer varieties. On the whole, fruit trees and bushes are healthy and free from disease; they are consequently laying a good foundation for next year's crops. The sun-heat in June warmed the soil more than for nearly two years, and abundant rains have since fallen. *H. J. Clayton, Wiarje Bank, Ullersby.*

—All kinds of fruit trees flowered splendidly. Apples will be a very good average crop, but Pears are disappointing. Raspberries and Gooseberries are good crops; Currants (Red and Black) very poor. Peaches and Apricots are good crops; Strawberries could not be better. *G. P. Bond, Grimsdon Park, Tadcaster.*

—The fruit crops in this district are very uneven. Apples and Plums are average crops; Pears are a very thin crop; small fruits have been good in quality and plentiful, especially Strawberries. It is difficult to account for the failure in some districts; the bloom was abundant, but soft to the touch, and the wood buds, as a rule, were too far forward. We had no severe frosts in May; the wood may have been imperfectly matured after the sunless season of 1907. Maggots are one of the chief causes of failure in Pears. They also attacked Apples and Plums, and their ravages will weaken the trees. *F. Jordan, Warton Priory, York.*

—Apples are an average crop in this district; Lane's Prince Albert, Worcester Pearmain, James Grieve, Domingo, Keswick Codlin, and Warner's King are carrying heavy crops, others only moderate. Pears are very poor. Apricots and Peaches are failures; all small fruits are abundant, and Strawberries very good. *A. E. Sutton, Castle Howard Gardens, Welburn.*

3, ENGLAND, E.

CAMBRIDGESHIRE.—There was an abundance of bloom on both Apple and Pear trees, but a great number of the fruits dropped off, especially the Apples, owing chiefly to a bad attack of the winter moth caterpillar. They denuded some of the young trees in the orchard, and would have done more damage had they not been picked off. Some fruits were completely picked through the centre. All the trees were sprayed twice during the winter months with the caustic alkali wash. *T. W. Birkinshaw, Hatley Park Gardens, Garmington.*

—Apples here are a good, clean crop, particularly early and mid-season varieties. Pears are good; the varieties Jargonelle, Louise Bonne of Jersey, Marie Louise, Durondeau, and Doyenne du Commerce being heavily loaded. Plums are scarce; all bush fruits, including Raspberries, are good and plentiful. Strawberries were abundant and of good quality. The soil of this garden is very light, on a bed of chalk, consequently we benefit by showery weather. *B. Goodwin, Monton Paddock, Neosport.*

—The sharp frost (12) which occurred on the morning of April 23 ruined the Apricot, Damson, and Plum crops, as the trees were in full bloom at the time. Strawberries and Apples were not in flower, and thus escaped injury. The late varieties of Strawberries have been much affected by the drought. The soil is of a heavy loam, with clay subsoil. *W. J. Snell, Wimpole Hall Gardens, Nr. Royston.*

ESSEX.—On the whole, the fruit crop is not so good in quantity as I had hoped it would have been. Apples, Pears and Plums, when in bloom, gave the promise of a good heavy season, but the flowers set badly, and later many fruits, being imperfectly set, dropped. Splendid growth has been made on all fruit trees this season. *A. Bullock, Copford Hall Gardens, Epping.*

—Small birds did so much damage to the buds of Currants, Gooseberries, and Plums in this district that they partly ruined the crops. *W. R. Johnson, Stoney Hill Gardens, Nr. Colchester.*

—Owing to a heavy fall of snow, lasting 18 hours, on April 23 and 24, followed by 11 $\frac{1}{2}$ of frost on the 25th of that month, Apples, Plums, Apricots, and Nuts suffered considerably. *James Vert, Audley End Gardens, Suffolk Walden.*

—Although the heavy hailstorm which we experienced in the early part of June severely thinned the fruits on some of the heavily-cropped trees of Apples and Pears, the fruit

crops for 1908 will nevertheless be good in this district. Among other varieties of the Apple that are bearing heavy crops of fine, clean fruits may be mentioned King of the Pippins, Norfolk Beefing, and Hambleton's Deux Ans. Gooseberries and Black Currants and Raspberries are immense crops. Strawberries have also been a heavy crop. The Loganberry is bearing freely, and making plenty of growths for producing fruit next year, the large, conical-shaped, dark-coloured fruit possessing a pleasant sub-acid flavour. *H. W. Ward, Lime House, Rayleigh.*

LINCOLNSHIRE.—Pears are the most disappointing crop this year, although there was an abundance of blossom. But the low temperature prevailing at the flowering period and subsequently (not that there was any sharp frost) seemed too much for them, as the greater number of the fruits dropped off. Apples are a splendid crop, the fruits clean and growing well. Peaches suffered much from the dull, cold weather last year, the wood being soft and devoid of the usual supply of fruit buds, but the trees are growing well, and have suffered less from pests than usual. Plums are a good crop, which is rather surprising after the very heavy crop last year. *H. Vindon, Marlston Manor, Grantham.*

—The Peaches and Nectarines, also Apricots outside, are practically a failure, due to insufficiently-ripened wood, the result of last year's fall, sunless summer months, the flowers falling even to properly expand. *E. C. Stainby, The Gardens, Brocklesby Park.*

—Peaches, Nectarines, and Apricots are the only crops below average. I think the wood was not sufficiently ripened last year, so the buds did not mature properly, with the result that there were few perfect flowers on the trees. Strawberries have been very plentiful and good in quality. *F. Barton, Hainton Hall Gardens, Linsith.*

—Apple crops are good, although a great many dropped off, owing, I think, to the cold and dry months of May and June. Apricots are almost a failure. Plums, on the whole, are good, especially in sheltered places; they are over the average. Loganberries are a heavy crop. Wineberries, although only in bloom, are also showing well. *John Hoop, Kimbly Hall, Grantham.*

NORFOLK.—The fruit crop in Norfolk promised to be a record one, for although the summer of 1907 was wet, cold, and sunless, some good weather was experienced in September and October, which was very beneficial for ripening the wood of all fruit trees and bushes, and everything promised well. March set in with cold, damp, sunless days, with slight frost by night, which retarded the buds. In the first and second week in April the weather improved with fine, sunny days: the result was a wealth of bloom on Plums, Pears, Cherries, Apricots, Peaches, Currants, and Gooseberries, with the flower clusters of Apples and Strawberries advancing rapidly, until the fatal evening of April 22, when snow began to fall, and continued for 36 hours without ceasing. On the nights of the 23rd and 24th we experienced 8° and 9° of frost, which destroyed most of the advancing bloom except in very sheltered spots. The result is a thin crop throughout. Strawberries and Raspberries have also suffered from drought, and the season is thereby shortened. *Isabel Smith, Shotsham Park Gardens, Nr. Norwich.*

SUFFOLK.—Owing to a very backward spring in this district, Apple and Pear trees were late in coming into blossom, and the flowers were very scarce on some varieties, owing, no doubt, to late season being so cold and sunless, resulting in unripened wood. Another cause of failure in the Apple crop was a plague of caterpillars just at the time the flowers opened, which nibbled petals and leaves. An orchard near here at one time had not a leaf on the trees; all of them were eaten off. Small fruits and Strawberries have been abundant and good crops. We are still picking (July 26) plenty of Givon's late Profuse Strawberry. Peaches, and Nectarines are good on south walls, and there is very little blight this year. *Tom Simpson, Hunsay Gardens, Wangford, Suffolk.*

(To be continued.)

PLANT NOTES.

EPISCIA FULGIDA.

THOUGH this, I believe, is the correct name of this pretty Gesneraceous plant, it is far better known in gardens and nurseries as *Cyrtodeira fulgida*. When confined to a single stem it forms a Gloxinia-like plant, whose stem is well furnished with leaves oblong in shape and from 6 to 8 inches long. They are of a deep metallic green colour, with the midrib and principal veins of a silvery whiteness, and consequently they stand out in a most conspicuous manner against the darkened surface of the rest of the leaf, which is curiously wrinkled. The flowers, borne on stalks about 2 inches in length, are tubular in shape, with the five-lobed expanded mouth a little more than one inch across, and of a very pleasing shade of bright rosy-scarlet. A succession of these flowers is kept up for a considerable time. To confine the plant to a single stem, the stout runners, which are freely produced, must be kept cut off. If allowed to develop, they form young plants on the points, so that, grown in a suspended basket, a very pretty effect is produced. This *Episcia* was introduced from Columbia about 30 years ago, at which time ornamental-colored plants were very popular. A blue-flowered species, *Episcia chontalensis*, was introduced from Nicaragua by the late Dr. Berthold Seemann in 1867. It is pretty, but less showy than *E. fulgida*. The roots of these *Episcias* are not tuberous, but strictly fibrous.

CROSSANDRA UNDULEFOLIA.

THIS is an extremely pretty warm house plant, and one that flowers at any time during the summer months. It is a member of the large order Acanthaceae, and though the arrangement of the blossoms is much the same as in many of its allies, their colour is, as far as I know, quite distinct from any of them. Like the *Apelandras* and others of its immediate relatives, this *Crossandra* forms an erect-growing half-shrubby plant, whose upright stems are clothed with ovate-acuminate leaves, about 6 inches long, and of a deep, shining green, with waxy edges. The individual flowers are about 1 inch across and of a rich orange-salmon tint. The flowers are borne in a terminal spike-like head, from which a succession is kept up for some considerable time. It is of easy propagation and culture, for cuttings of the young shoots make roots without difficulty during the spring months, and the young plants thrive in ordinary potting compost. Like most members of the order Acanthaceae, the stoutest cuttings are preferable, as the young plants must not be stopped, for it is the stout, sturdy shoots which bear the finest heads of blossoms. Though a certain amount of heat is necessary to its well-doing, this species succeeds better in the intermediate house than in the stove. It is a native of India, and was first distributed by the late Mr. William Bull, of Chelsea, in 1881, under the name of *Crossandra intundibuliformis*. *W.*

AMERICAN NOTES.

ROSE MY MARYLAND.

THIS variety, which was exhibited last season, is apparently an excellent grower. Notwithstanding the intense heat of the past few weeks, young stock, including both grafted plants and others upon their own roots, look exceptionally well, the growth being clean, healthy and full of vigour, with no sign of mildew or spot.

CATLEVAS AS CUT FLOWERS.

CATLEVAS are becoming increasingly popular as summer flowers for funeral decorations, and the reason is plain. When, owing to the great heat, the Roses, Carnations and other popular flowers are soft and poor in colour the flowers of *Catleva Gaskelliana* and *C. gigas* are at their best, capable of lasting well and giving the greatest satisfaction. The plants make a remarkably fine growth here, and they have a great future before them as market flowers. *H. R. R.*

NURSERY NOTES.

TANGLEY NURSERIES, HAMPTON.

DURING the past year or two Mr. W. H. Page has been a prominent exhibitor of Carnations, Lilliums, and other flowers, but though it is only recently that he has exhibited at flower shows, Mr. Page has long been a grower of the Carnation, and he was one of the first to cultivate the variety Miss Jolliffe in large quantities for market.

It was to see how Mr. Page cultivated Lis Carnations that I paid him a visit in May, and his nurseries I found full of interest.

The Carnation houses are something over 100 feet long and 30 feet wide. The best flowering plants were from two to three years old. All the plants are grown in pots, the largest recep-

Striped Lawson. Some of the plants were reserved for stock purposes; these had produced flowers of a brighter colour than the ordinary type. Amongst the plants of Enchantress, the white and also the rose-pink varieties have appeared, and many plants have produced flowers of a very deep shade of bluish-pink. The centre of one house was filled with plants of the variety Queen Louise; many of the specimens were upwards of 5 feet in height, and they had furnished a succession of flowers since last October, and looked promising for a still further supply of bloom. My Maryland had proved the most prolific bloomer during the winter, and the flowers had been of the best quality. White Perfection is found to be a reliable variety for winter flowering. Amongst crimson-coloured varieties, President Roosevelt was flowering freely; this has given a more regular succes-

the bulk of the stock consisted of *L. longiflorum* giganteum.

Narcissi are another feature of these nurseries. About 660,000 bulbs of *N. ornatus* were forced during last spring. Other varieties are also forced in large quantities, and all the bulbs are raised in the nursery. About 30,000 Roses are grown in large pots for forcing, and many are panted out. The portable or travelling glasshouses are found useful for Roses. Three sections of the Rose beds are covered successively. I enquired if any difficulty was experienced in moving the houses, and was told that they moved easily; the rails are laid in a good bed of concrete. The varieties of Roses most extensively grown are Frau Karl Druschki, Liberty, Mrs. Sharman Crawford, Mrs. J. Laing, Capt. Hayward, and General Jacquiminet. *A. Hemslcy.*

FIG. 41.—A BOUQUET OF CARNATION ENCHANTRESS AS EXHIBITED BY MR. W. H. PAGE, TANGLEY NURSERIES, HAMPTON.

tacles being 8 inches in diameter. The stock consists of more than 50,000 plants, and immense quantities are raised yearly, some for sale and others for succeeding those that are worn out. The oldest plants seemed to be giving the best results, for they were flowering freely, and the blooms were of large size and good in all respects. Two of the largest houses were filled with the variety Mrs. T. W. Lawson, which is a favourite kind with Mr. Page. In a house containing three-years-old plants, my attention was directed to some sports, and Mr. Page remarked that it was only amongst the older plants that he had found variations, not only in the case of Mrs. Lawson, but other varieties also. The white variety of Mrs. T. W. Lawson was of the best type; others of these variations included one which appeared almost identical with Winsor, and there were some which resembled Melody, Prosperity, and I

son of blooms than Harlowarden, which is also grown extensively in this nursery. In a house devoted to Britannia I noted a plant which had sported, one portion having produced flowers of a beautiful shade of salmon-pink; it should prove a valuable addition to existing varieties. All the new American sorts are being tried. The potting of young plants into 5-inch pots was in progress at the time of my visit. It may be of interest to note that some of the old plants, which were left out in the open until the end of October last, flowered well after they were taken in, and they were quite free from disease, whilst others, which were housed early, did not entirely escape the rust fungus.

Lilliums are another great feature at Mr. Page's nursery, and upwards of 100,000 bulbs of *L. longiflorum* are grown annually. All those in flower, when I saw them, were from retarded bulbs. The variety formosum was very fine, but

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. G. L. HOLFORD, C.V.O., C.L.E., Westonbirt, Gloucestershire.

Burlingtonia.—The plants of this genus are amongst the most beautiful of small-flowered Orchids. They are easily grown, have a free-flowering and compact habit of growth, and the flowers are capable of lasting some weeks in beauty if kept free from damp. These dwarf epiphytes thrive best in small baskets, or pans, and the plants should be suspended from the roof rafters in an intermediate temperature, such as the Cattleya house affords, where, owing to the amount of light and air available the plants usually make satisfactory progress. With regard to the rooting medium, an ordinary mixture of *Osunda* root, or *Polypodium* fibre and *Sphagnum*-moss suits these plants well. The drainage should be ample, and each plant

surfaced with clean chopped sphagnum-moss. During the season of growth a very free supply of water is necessary, but when the plants are resting this may be greatly diminished, yet not altogether withheld, for if allowed to get dusty at the roots, the plants will make but weak growths in the following season. Small white scale is the worst insect enemy, and it is very difficult to thoroughly eradicate, though it may be kept in check by timely sponging with some safe insecticide.

Zella rubescens (pedunculata).—This species is a charming, compact-habited, dwarf-growing plant, and one that flowers during the dull winter months. The plants grow best in shallow pans, or baskets suspended in the intermediate house. As new roots are about to be made from the base of the young growths fresh rooting material may be afforded those that are in need of it. Make use of a similar compost to that advised above for Burlingtonias, supplying liberal drainage, so that water may be applied freely when the plants are in full growth and developing their little pseudo-bulbs.

Heating of boiler.—The present month affords a suitable time for the overhauling of the heating apparatus, putting the same in good working order ready for winter. A careful examination should be made of all joints, and any that leak must be made good. The valves and air taps should be examined and made easily removable. Boilers that are old and worn should be replaced with new ones while the weather is favourable for such work being done without much risk of injury to the plants. If boilers are left until they completely break down, there is always the risk of this happening during severe weather in winter. As I have pointed out already in these columns, I prefer the sectional type of the many good boilers now on the market.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq.,
Kear, Peatshshire, N.E.

Panacratium fragrans.—Many bulbs are now showing for flower, and a number of them may be placed in a cooler atmosphere, such as that of a warm greenhouse, which, serving to retard the flowering, will prolong the season of bloom. During the time they are in the cooler atmosphere water must be only sparingly given, in order that they may not suffer from the changed conditions. As soon as the plants have flowered they should be removed into heat again, and any that require to be re-potted should be given attention. A suitable compost is one similar to that recommended for Nerines, but the loam in this case may be a shade heavier in texture. As a rule, Panacratiums are best grown singly in 6 or 7-inch pots, but if cuttings are wanted for exhibition purposes in pots of larger size, two or more bulbs must be put together, taking care to select bulbs that flower at the same time, otherwise they will not be satisfactory, for the bulbs cannot be induced to flower at the same period unless it is natural to them. Panacratiums require free waterings during the period of growth, therefore the pots should be well drained in every instance.

Crinum Moerei.—In order that this Crinum may flower in autumn the plants should be kept all the season in a cool greenhouse and treated much in the same manner as described in last week's Calendar for Nerines. When re-potting is necessary, use a richer and heavier soil than for Nerines, but Crinums succeed best if not disturbed frequently. Shake out the bulbs carefully, and put one large bulb in an 8-inch pot. Place them in an intermediate house until growth is completed; then dry them off and place them in a greenhouse, withholding all water. Re-potting should not be done until the plants have flowered.

Show and decorative Pelargoniums.—Plants that have done flowering if not turned out-of-doors should be placed in a position exposed to full sunshine. Water should be very sparingly given at this period, decreasing the supply until it is withheld altogether. After that stage has been reached the plants should be laid on their sides for a period of rest until the wood is quite ripe, after which time old plants should be pruned hard back. Younger plants should have the wood left rather longer so as to form larger plants next year. If young stock is desired, the present is a good time to take a batch of cut-

tings; they will root quickly at this season. Select firm, ripened wood for the cuttings, and insert them in sandy soil, making them firm. Place them in an unheated frame fully exposed to the sun. As soon as they have rooted they should be potted off singly into 3-inch pots, using as a compost good fibrous loam, leaf-soil, and enough sand to keep the whole porous. A few very small bones may be added, these being more lasting and better than dung. In potting make the soil moderately firm. The pots must be well drained, as Pelargoniums in autumn and winter will perish if water persists in the pot. They should be kept rather on the dry side, and during the winter water should be very sparingly given. As soon as growth becomes active after re-potting, the point or top of the shoot should be pinched out so as to induce the shoot to break and throw out three or four side growths. These side growths as soon as long enough to handle should be carefully tied down to the sides of the pot, so as to form a compact bushy plant. Pelargoniums being very subject to green fly, the house should be fumigated on its first appearance. If there is not a house that can be devoted to the plants, place them on a shelf close to the glass in a greenhouse, or in an unheated frame fully exposed to the sun.

Chrysanthemums.—Plants cultivated for supplying large blooms are now setting their flower buds, and all buds should be secured by the middle of August. Great care should be exercised in removing the wood buds around the flower bud, destroying them gradually, at different times, down from the flower bud. At this date the plants should be top-dressed with a compost much the same as that used for potting, adding a favourite artificial manure. From this date onwards feed the roots at regular periods, but feeding must be discontinued before the plants are housed in September.

THE FLOWER GARDEN.

By W. FIFE, Gardener to Lady WASTAGE, Lochline
Park, Dorkshire.

The propagation of Zonal Pelargoniums and other bedding plants must soon be given attention. Pelargoniums may be rooted in boxes placed out-of-doors, early and well-rooted cuttings, if hardened by exposure before being placed under glass for the winter, always give the best results. The more tender plants, such as Coleus, Iresine, and others, will require to be rooted in a frame or pit kept somewhat close for a few days and shaded from sunshine. Cuttings should always be selected from healthy plants, choosing only the best varieties, and from moderately well-ripened and firm parts of the plants. Cuttings of young, unripened stems are apt to decay. In shoots that are very old and dried make roots with the greatest difficulty. A few of the lower leaves should be taken off, and the stems cut immediately under a joint. Sharp, sandy soil is the best, and the holes should be made with a blunt-pointed dibber rather thicker than the cuttings to be inserted. Press the soil gently but firmly round the base of each cutting, firm enough to prevent the cuttings coming out readily when gently pulled with the finger and thumb. The receptacles for containing the cuttings should be clean and well drained. When roots have been made the little plants may be separated singly or as desired.

Plants in tubs.—Sweet Peas are very suitable subjects for cultivation in tubs placed close to the mansion or dwelling-house. In a somewhat shaded position the colours of the flowers last longer. Close attention is necessary to watering and feeding the roots, and to the removal of all decayed flowers before seeds form. Clumps from 8 to 10 feet in height, if well flowered, are very attractive. *Alyxia cutirodora* is esteemed for its fragrance, and when well cared for assumes considerable proportions. Cuttings rooted here in 1892 have long since attained the limit in size imposed by the necessity for housing them in winter, being 12 feet in height, with a diameter of 8 feet and of pyramidal outline. Slight winter protection alone is necessary, and all growth is made in the open. The plants being now in full flower, are abundantly supplied with water and occasional stimulants. The Myrtle is another favourite for cultivation in tubs, and is much admired in the month of

August when in full flower, especially if the specimens are, say, 10 feet in height and 6 feet in diameter. Cuttings rooted here six years ago are nearly that size, and they are now in full bud. Myrtles should be firmly potted in rich, loamy soil with leaf-mould and sand. Scented-leaved Pelargoniums, like the low-leaved varieties, are attractive as pyramids. The specimens should be such as measure from 7 to 8 feet in height and 3½ feet in diameter. When they have attained these dimensions the prunings are useful for mixing with cut flowers, to which they add a most pleasant odour.

Campulida corpicata and the variety *alba* are very useful at this season as border or rock plants, the profusion of their flowers at the present time being a feature worthy of remark. The hardness of this species is in its favour, and the stock may be easily increased by division, by seeds or by cuttings, but cuttings inserted early in spring are to be preferred if a limited stock only is required. If pushed out into sandy soil in a cold frame, they will soon make roots.

Spanish Brown.—*Genista hispanica* is a very effective feature in the borders or shrubberies at this season; the effect is especially good when the *Genista* is associated with *Prunus Issardii*. Plants may be easily raised from seeds, which are produced in great quantities and should be gathered before they are quite ripe. Let the seeds be grown in the open ground, but they may not appear above the soil until the following spring.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to THE DOWAGER LADY
NORBENBOLM, Watter Vicoy, Yorkshire.

Vines against walls.—A very warm, sunny season is absolutely necessary to ripen out-of-door Grapes, and these conditions are seldom obtained. The foliage is ornamental, however, in every season. In order to give the Grapes a chance to ripen proper attention should be given to the shortening and thinning of the growths, stopping the shoots at one leaf beyond each bunch, and the laterals and sub-laterals also at one leaf. If a little attention can be given to moderately thinning the bunches so much the better. Leading shoots for extension and for covering bare wall space may be allowed to extend 5 or 6 feet before being stopped. Keep a sharp look-out for mildew, and immediately it is seen dust the leaves with flowers of sulphur. A good watering with liquid manure will be helpful to vines growing in a hot or dry position, and bearing a moderate crop of fruit.

Strawberries.—As soon as the fruit has been gathered from young plants that will be cultivated another season, let the plants be cleared of all runners and damaged and useless leaves, cleaning the ground of weeds at the same time. If the best can be done, the ground by means of the hose-pipe, to encourage fresh growth, that the plants may become furnished with healthy foliage before winter. If the plants have suffered badly from mildew, remove the mulching or other refuse to the fire heap, but I do not advocate the removal of too much foliage, as this tends to weaken the crowns. Dust the beds over with a mixture of soot and lime. Let old plants which are exhausted be cleared from the ground without delay, that the soil may be broken up or planted with winter Brocoli or similar crop. Runners that were layered as recommended in a previous Calendar will now be rooted and ready for planting out. Early varieties should be planted as soon as possible, for provided the weather is favourable and the soil in good condition the present is the most favourable season to make new beds. If the ground was prepared as recommended in the Calendar for July 11, insert the plants at distances of 1 foot apart in the lines and allow 2 feet apart between the rows. A few plants should be put out at 1 foot apart each way on a warm border, and if frames be placed over them next spring they will give good returns for little trouble. All planting should be completed by the end of August if possible.

American Night.—Keep a sharp look-out on the fruit trees for this pest, and rub over the affected parts with a stiff brush dipped in methylated spirits. In bad cases, and especially if the trees are not bearing crops, syringe the trees with a strong insecticide, repeating the application again when necessary.

FRUITS UNDER GLASS.

By 1. COOMER, Gardener to Lord Llangatfeck,
The Hendre, Monmouthshire.

New Peach borders.—There is much to be gained by planting trees as early in the autumn as is practicable, therefore it is advisable to prepare the borders in ample time. Good drainage is important, and for this reason the bottom of the trench should be concreted, and covered with a layer, 9 inches or a foot in thickness, of stone, or brick rubble. On the top of this place thin turves, with the grass side downwards. A 4-inch tile drain should be placed in the drainage material and slightly sunk in the concrete. The compost should consist of rich fibrous turf, roughly broken, and mixed with crushed mortar rubble, finely-crushed bones, and wood ashes, made, if possible, from charred green wood, more or less liberally, according to the texture of the loam. The last-named should be used in a tolerably dry condition, and be well consolidated. The compost should be from 2 to 2½ feet in depth, and the borders may be formed wholly inside, or outside, or the roots of the trees may be allowed to ramify in both inside and outside borders. The borders may be wholly formed in one season, or upon the piecemeal principle, as is desired; but this will be in a measure controlled by the construction of the house and the position that the trees will occupy. The kind of trees to be used, whether standard or dwarf specimens, will be governed also by the build of the house. Order the trees well in advance of the planting season, and remember that it is a good plan to have them growing for a season or two against an outside wall before planting them indoors.

Fig trees in pots.—Early forced trees that have been gradually hardened since maturing their second crop of fruit, by free ventilation and exposure to sunshine, may now be placed out-of-doors in a sheltered position in full sunshine. The pots should be plunged in a bed of ashes, or tree leaves, and each should be examined occasionally to see that the drainage is in perfect condition. Copious supplies of water will still be needful, but do not apply manure or manure water. Young trees that were afforded a shift into larger pots, as advised in a previous Calendar, should now be placed in similar conditions to the early-forced trees, provided the roots have made satisfactory progress. Trees now fruiting must be kept under glass until the fruit is gathered, when these trees also should be carefully hardened and placed in the open.

Late-fruiting Fig trees in borders.—Keep the growths well thinned out and regularly stopped. This is especially important in the case of such robust growers as Negro Largo, otherwise the growths will not colour satisfactorily and the wood will fail to mature. The fruits should also be thinned. Apply a top-dressing, or waterings with liquid manure to the roots, and water the borders as often as required. Syringe the trees with clear water every afternoon when closing the house for the day. As soon as the fruits commence to colour, it will be necessary to discontinue syringing the trees, and extra care must be taken to ventilate the house a little early in the morning, increasing the amount during the hottest part of the day, thus preventing condensation of moisture upon the fruit.

Strawberries.—The plants should be rearranged in order to place them more thickly that the leaves may have room to properly develop. Move each plant once every week to prevent the roots from penetrating the bed of ashes, and remove runners as soon as they can be grasped by the fingers. Attend closely to watering, using clear water until the soil is well filled with roots, when a mild liquid manure should be occasionally given. Syringe the plants overhead in the evening of fine days. In cases where wire gauze has not been employed to prevent the ingress of worms, these pests may become troublesome, and the use of clear lime water may be necessary to remove them.

Bananas.—Young plants that have been tubbed or planted out a sufficient length of time to have made numerous roots should be given diluted drainings from the cow-shed, or suitable artificial manures. Keep the atmosphere moist and hot, and apply abundant waterings to the roots. Any plants which have

fruted in tubs should be thrown away, unless they are required for propagation, but those that are required for propagation, and are not exhausted, should be cut down, and suitable suckers selected for cultivation under the same conditions.

Winter Cucumbers.—About the second week in August is a suitable time for sowing seeds of Cucumbers for fruiting in winter. Sow the seeds singly in 3-inch pots, filled with a fine, moderately moist compost of loam and leaf-soil. Plunge the pots in a hot-bed in a house having a temperature at night of 70° and a moist atmosphere. The seeds will not require watering until after the plants are through the soil, when the pots should be placed in a light position near the glass. As soon as a rough leaf has expanded the plants will be ready for being shifted into 6-inch pots. They should be ready for planting out about a month after the time that the seeds were sown. For the final planting fresh fibrous loam and flaky leaf-soil, with a little sand added if the loam is heavy, should be forced into small hillocks, resting on thin turves placed on a bed heated with hot-water pipes. After the soil has become warmed through, a plant should be planted on each hillock.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GRUBS, Aldenham House, Elstree, Hertfordshire.

Potatoes.—I never remember to have seen the Potato crop, including early, mid-season, and late varieties, look more promising that it does this season. With a continuance of fine weather, not only should the crop be heavy, but it may be expected that the quality will be of the highest. All varieties should be lifted immediately the growth is completed. A mistake idea exists that unless the tubers are thoroughly ripened, so much so that the skins cannot be easily rubbed off, the crop is not ready for lifting, the consequence being that in many cases disease attacks them and a very great proportion of the crop becomes useless. I have proved over and over again that the rubbing of the skin, though a little unsightly at the time, does not impair the keeping qualities, as in a very short time the rub becomes healed, and the tubers are none the worse.

Late Peas.—Every attention should be paid to these, so that the season may be prolonged as late in the year as possible. Fortunately, we now have varieties with robust constitutions suitable for late cropping, and when grown under proper conditions, they seldom fail. The most essential requirements are to deeply till the soil, apply abundant moisture at the roots, spray the tops during hot weather, thoroughly mulch the ground, thin the plants to a sufficient distance apart, and, in many cases it will often be necessary during a wet period, and as the season advances, to pinch out the points of the growth after a satisfactory quantity of flowers has set. For some years past we have relied principally on two varieties, namely, Wells's Masterpiece and Autocrat. The first-named variety is a magnificent Pea, possessing a fine constitution; it is seldom attacked by mildew, is very prolific, and, above all, has excellent quality. This variety often continues to bear well into November. Autocrat seldom fails in any season or locality.

Onions (spring sown).—By August 20 these should have practically completed their growth, and it should be borne in mind that the earlier and more perfect the ripening, the better will be their keeping qualities. The chief reason why large specimens frequently fail to keep satisfactorily is owing to imperfect ripening, and not sufficient care being taken to prevent them being bruised. Should dry weather continue, one more good soaking of water should be given at the roots, which should be sufficient.

Sowing Onion seed.—Preparations should now be made for getting the ground in order for sowing the Tripoli varieties, and where it is intended that the bulbs should finish their growth where they are sown, the ground should be such as was recently trenched deeply, and it should be heavily manured. Instead of this, I prefer to sow the seed on deeply-dug ground which was liberally manured by a previous crop, give the surface a thorough dressing of soot and wood ashes, and transplant the seedlings to their permanent quarters early in spring. In any

case, the surface should be made very firm and broken down to a fine tilth, and the seed should not be sown before the middle of the present month (about the 20th inst. for choice), otherwise a very large percentage is certain to run prematurely to flower. Splendid varieties for this sowing are White Emperor and White Leviathan, both of which are distinct. The first-named variety, though not quite as large as White Leviathan, is fully ten days earlier. For succession, Lemon and Blood Red Rocca are each good, and, if lifted in time, will keep well.

Radishes.—Continue to sow these in small quantities about every ten days. Select a shady, cool spot in the garden, and damp the surface daily.

Aboriginis.—Plants growing in pots and now coming into bearing, should have a liberal supply of manure water and the foliage thoroughly syringed with tepid water twice a day. The fruits of these plants ripen better if the plants are kept in an intermediate house, but in this case care must be taken to keep the atmosphere in a moist condition, in order to prevent attacks of red spider. Although during hot weather in August Aboriginis can often be satisfactorily grown in cold pits or frames, and even in the open, it is advisable, owing to the variable climate and the uncertainty of the crop, that, wherever possible, they should be cultivated and ripened in heated houses. The purple variety is generally considered superior for culinary purposes, but the white one is very ornamental, and it is therefore advisable to grow both. The demand for this vegetable is becoming greater year by year, and in order to supply our markets large quantities are annually imported.

Endive.—Continue to plant out good breadths of this as the plants become ready, allowing a distance of 12 inches apart. Make another good sowing of seeds of two or three varieties on a south border.

THE APIARY.

By CHLORIS.

Queens.—Many beekeepers raise queens, and some sell them, but I wonder how many really understand queen-raising. There is the temper of the bees, as well as the prolific breeding capacity of the queen to consider, together with the industry and hardness of the strain. Further, what about the males; are they descended from bees noted for longevity and honey-gathering power? These and other points are necessary to consider when raising the best kind of queen.

Queen cell containing dead worker bee.—When a hive that had swarmed was being examined to see if the young queen was laying, a sealed queen cell was discovered and duly removed. To the beekeeper's amazement, a worker was discovered in it. The head was foremost, and it is evident that the worker was helping itself to the "royal jelly" left after the hatching of a queen, and the other workers, finding the cell occupied, sealed it over.

The caps of honey jars.—Some beekeepers have been advised to leave off the caps of the honey bottles, after the honey has been bottled, so as to allow the air bubbles to rise and be skimmed off. I think it would be better to cap at once, for there is always the fear of fermentation arising when the honey is exposed in this manner.

To get bees from roofs and hollow walls.—A little while ago a swarm took up its residence in the roof of a porch. The people were in a state of panic, for no one would venture out by the front door, and many friends were notified of the danger. I was sent for, and asked to overcome the difficulty. The procedure is simple. Make sure that there is only one entrance or exit; over this place a Porter bee escape, and just above put a weak stock of bees, either in a straw beehive or on three frames. The swarm can only go out foraging, but cannot return to their old quarters, and will soon join those above in the hive. If the bees have been in the roof for some considerable time, it will take about a month to clear them, but if they have only just settled there, then three or four days will suffice. Whilst the operation is in progress, frequent examination must be made to discover if the bees are using some other entrance than the old one where the escape has been placed.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of Plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Correspondents should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturalists.

Newspapers.—Correspondents sending newspapers should be warned to mark the paragraphs they wish the Editor to see.

SALES FOR THE ENSUING WEEK.

FRIDAY

New and rare plants and seeds from New Zealand & those imported and established Orchids. Orchids in flower and bud, at 67 & 68, Cheapside, E.C.

Complaints are periodically made on the subject of injuries sustained by handling various plants which contain juices or other substances that produce inflammatory or other disagreeable symptoms on the skin. In some years these disagreeable effects are more noticeable than in others, and it seems tolerably clear that, in the case of some of the offending plants at any rate, a hot, sunny summer tends to accentuate the evil. A plant which is the cause of part, at least, of the trouble is *Rhus radicans*, or, as it is sometimes called, *R. Toxicodendron*. It is grown in a fairly considerable number of gardens in Britain, but instances of trouble arising from it are somewhat rare and scattered. In its native home, North America, it is well known as a dangerous plant, under the name of *Pois à Ivy*, and a stranger does well to learn to readily distinguish it from the somewhat similar and very common Virginia Creeper, especially as both plants are not infrequently to be found growing over the same tree. Even in America its virulence seems to vary according to climatic and other conditions, and, furthermore, some people are far more sensitive to its effects than others. Indeed, we have been informed on reliable authority that at the time when the plants are in flower there are people who are compelled even to leave the districts where the plants are common, doubtless owing to the poison being contained in, or conveyed on, the pollen grains. There are, however, fortunately, not many who are as sensitive as this would imply, although the evil effects consequent on incautiously handling the plants are everywhere recognised in America, and we have on several occasions witnessed them ourselves. It is, then, a curious fact that in this country the plant should be relatively

innocuous, save under exceptional circumstances as already indicated. The poisonous principle resides in the juice or latex present in the leaves and stems of the plant, but the composition of the juice plainly varies according to the condition under which the plant is growing. In the south-east of England we have heard of more cases than elsewhere, and perhaps this is to be attributed to the hotter and more continental type of summer which prevails in this part of the country, for cases of poisoning seem to be less frequent in other districts, and to be almost unknown in the north.

Another species, not uncommon in America, and apparently even more dangerous than *R. radicans*, is *R. venenata*, known locally as the Poison Elder. Some of the species that inhabit the warmer parts of Europe are also injurious in their natural habitats, although they are not generally regarded as endowed with bad qualities when grown in this country. The Wig tree, *R. Cotinus*, as well as *R. Coriaria*, which are both natives of the Mediterranean region, are looked on with suspicion in the south of Europe. The latter plant is unquestionably dangerous, and produces an erysipelas-like affection of the skin of persons who gather the leaves for the sake of the tannin they contain.

Some of the best-known examples of the poisonous qualities of the genus are met with in those species which, like *R. verniciflora*, furnish the well-known lacquer varnish used by the Japanese. The juice is so dangerous that its nature is not as yet fully understood, but the poisonous substance, formerly called urushic acid by Dr. Yo-hida, is probably a phenol, to which the name of Laccol has been given by Bertrand, a French chemist, who has devoted much time to its investigation. The varnish results from a chemical change in this laccol produced by a ferment, also present in the juice, when the two substances are exposed to the oxygen of the air.

Another group of plants which is endowed with analogous disagreeable qualities is furnished by some of the Primulas. The two species which enjoy a bad reputation in this respect are *P. obconica* and *P. sinensis*. The latter plant, however, is rarely productive of bad effects, although we have received complaints respecting it from time to time. There is a more general agreement as to the *P. obconica* deserving its evil name. But just as in the case of the Sumachs, or species of *Rhus*, so also with this plant, different persons exhibit very different degrees of susceptibility. Some interesting experiments were made at Prague a few years ago which very clearly showed this. Portions of leaf petiole and the peduncle of the inflorescence bound on the wrist or arm for a short time, produced very marked effects upon one of the investigators, whilst in the case of another subject hardly any result was obtained. It was clearly shown, however, that repeated application of the stimulus did not confer any immunity, such as might, perhaps, on analogy have been anticipated. Indeed, the contrary appeared to be the case.

The injurious substance is contained in the glandular hairs that occur on the epidermis of the plant, and perhaps in the more pointed hairs also, as the extraction of the

contents of the glands and the smearing of the yellowish mass thus obtained on the skin was followed by the characteristic symptoms that are so well known. It was also discovered that the injurious substance is insoluble in water, but is readily soluble in strong spirit, and this indicates how the unpleasant effects of handling the plant may be obviated. By rinsing the hands first with spirit, and then washing with soap in a stream of water, the symptoms may be almost entirely prevented, and even when they have already begun to manifest themselves, the alleviation is considerable. It thus becomes clear that it is of little use to wash the hands in water only, since this will not remove the poisonous substance, and it is to be hoped that those who are sensitive to the action of the secretion will give the methylated spirit method a trial. Seeing that the degree of susceptibility differs so widely, it will probably happen that some people may still suffer, even from the small traces that remain after treatment with the spirit, but it may be expected that the majority will derive considerable benefit from its use.

Some persons suffer from handling the bulbs of Roman Hyacinths, though the evil consequences usually are merely temporary. It is believed that the cause of the trouble in this case lies in the presence of needle-like crystals, or raphides, of calcium oxalate which occur in the dried-up cells of the scales. These easily penetrate the skin, and may set up a troublesome irritation. It is, however, doubtful whether the physical injury alone accounts for the unpleasant effects, and it may be that the needles really serve to inoculate the skin with some deleterious substance. Such is almost certainly the case in connection with some other plants, the *Arum*, for example. The juice of the tuber, if filtered, is said not to produce any effect if placed upon the tongue, whereas if the cut surface of the rhizome be directly applied, a tingling sensation makes itself felt in the course of a few minutes and gradually increases until considerable pain is experienced. This seems to be due to the introduction of a poisonous substance into the tissues, and not to be solely attributable to the irritation caused by the raphides. The matter is worth more extended investigation, as very little is known about it at the present time.

OUR SUPPLEMENTARY ILLUSTRATION represents *Dendrobium Brymerianum*, "Gatton Park variety," for which Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. W. P. BOTT), received an Award of Merit at the meeting of the Royal Horticultural Society on April 14 this year, and which is one of the most highly developed forms yet seen. The species was introduced in 1874 by Messrs. HUGH LOW & Co., from Burmah, and few Orchids have been better welcomed by Orchidists, although the supply for a good many years was very limited. The typical form was invariably good, and the branched fibrillation on the lip, which forms the chief attraction of the flower, well-developed. But in the *Gardeners' Chronicle*, January 28, 1888, p. 104, the late Professor REICHENBACH describes *D. Brymerianum* histrioidicum, which had been imported from Upper Burmah, and was appearing in many gardens. As with some other Orchids, this was an inferior presentation of the original species so far as the cultivator was concerned, for its flowers

were small, the fringe of the lip but poorly developed, and the flowers addicted to self-fertilisation, thus tending to expand, which rendered them florally worthless, though of scientific interest. It was probably this form which caused the species to have been confounded with *D. crinitum*, illustrated in the *Gardeners' Chronicle*, 1908, p. 184. The variety *histrionicum* has practically disappeared from gardens, and the more recent importations, out of which the Gatton Park variety appeared, have fortunately been of the best type, with large bright yellow flowers. *D. Brynerianum* thrives well with *D. clavatum*, *D. fimbriatum*, and others of the same section, all of these requiring warm moist quarters at the growing season, and a cooler resting period, during which water should be given but sparingly.

THE LATE MR. RICHARD LOWE.—Some interest arises from the death of Mr. RICHARD LOWE (see ante p. 78) on account of the fund raised for his benefit, which was administered by the Wolverhampton and Staffordshire Auxiliary of the Gardeners' Royal Benevolent Institution. Mr. TOM B. DOBBS, who succeeded Mr. LOWE as the hon. sec. of this auxiliary, being supported by Messrs. POSSER, JONES & CO., who initiated the scheme, and Mr. WM. JOHNSON, manager of the Metropolitan Bank, Wolverhampton. A meeting of the committee responsible for the management of the fund met recently, and a decision was arrived at as to the disbursement of a balance of £31 1s. 8d. The details of accounts are open to the inspection of subscribers on application to the Metropolitan Bank. We may add that Mr. LOWE's original premises in Queen Square, Wolverhampton, are now occupied by Messrs. TOM B. DOBBS & CO., landscape gardeners and rustic workers, who took over the business in 1892. Previously, the Messrs. DOBBS were engaged in the business of Messrs. HURST & SOX, London.

THE ROYAL SCOTTISH ARBORICULTURAL SOCIETY.—The present issue of the *Transactions* of this important Society is of permanent interest to all persons connected with forest management, and who may wish to see its aims brought home to the people of this country in a similar manner to that common in Continental countries. The Society holds periodical meetings for the transaction of business, the reading and discussion of papers, the exhibition of new inventions, specimens of forest products, and for the advancement of forestry in all its branches. Prizes are given to young students with the view of encouraging them to study and to train themselves in habits of careful and accurate observation; and the Society offers annual prizes and medals for essays on practical subjects, and for inventions connected with appliances used in forestry. Such awards have been granted continuously since 1855, and have yielded satisfactory results. The Society has strongly urged the creation of a British school of forestry, and with a view of stimulating public interest in the matter, a forestry exhibition, chiefly organised by the council, was held in Edinburgh in 1884. The Society in 1890 instituted a fund for the purpose of establishing a Chair of Forestry at the University of Edinburgh, and a sum of £584 has since been raised by the Society and handed over to the university. Aided by an annual subsidy from the Board of Agriculture, a course of lectures has been delivered at the university without a break since 1889. The Society has drawn up a scheme for the establishment of a State model or demonstration forest for Scotland. The Government has acquired the estate of Inverliver in Argyllshire, and this, it is

hoped, may prove to be the first step in a scheme of afforestation by the State of unwooded lands in Scotland. For the past 29 years excursions have been made to various parts of Scotland, England and Ireland. In 1895 a tour of 12 days was made through the forests of northern Germany; in 1902 a tour of 17 days was made in Sweden, and in the summer of 1904, the Forest School at Nancy and forests in the north of France were visited. The hope is expressed that landowners may be induced to afford facilities to their foresters for participation in these tours. The contents of the present volume include an article on "Trees of Western America," by F. R. S. BALFOUR; "A Scheme for Establishing a National Industry of Forestry," "The Cultivation of Hardwoods," by J. BOYD; "Impressions of Forestry in the Schwarzwald," by J. F. ANNAND; and "Continental Notes—Germany," by BERT RIBBONTROP, C.I.E. The articles on tours afford instructive reading to anyone interested in tree planting and afforestation, and who is unacquainted with Continental systems of forest management. The text is helped by some good figures of injurious insects and diseases. We learn that the membership is well maintained, and is at the present time 1,212. The president of the Society, Sir KENNETH J. MACKENZIE, Bart., of Garloch, makes an appeal to country gentlemen, factors, gardeners, foresters, land stewards, nurserymen, farmers, and others, urging them to become members. The hon. secretary is R. C. MUNRO FERGUSON, M.P., Rath House, Kirkcaldy; and the secretary and treasurer, Mr. R. GALLOWAY, S.S.C., 19, Castle Street, Edinburgh.

IDEAL HOME EXHIBITION AT OLYMPIA.—We are asked to state that practical illustrations of cottage gardening and bee-keeping are to form one of the most prominent features of the Ideal Home Exhibition at Olympia, which is being organised by the *Daily Mail*. The large annex, which covers over an acre of ground, is to be converted into "a corner of England." There will be a real model cottage, standing in a series of gardens laid out by a landscape gardener. One of the gardens will be on the French plan, and the system of growing vegetables under cloches and frames will be shown. Skilled operators will give practical demonstrations of the treatment of the soil and various other processes, whilst bee culture will also be shown by experts. In all, there will be over 20 operators, including those from the Studley Horticultural College, who will demonstrate every phase of garden work.

GOOD SUMMER CARNATIONS.—Three Carnations that have stood the summer heat well this season in America are White Perfection, Beacon (red), and Winsor (pink). In one of the largest establishments these fine varieties have produced splendid flowers when others have failed to have anything like a respectable appearance. All three will be largely planted again this season.

STATE AID TO AGRICULTURE IN AMERICA.—An example of the assistance afforded to the farming community of the United States, says the *Agricultural News*, by the Government Department of Agriculture is mentioned in a recent British Consular Report. Less than ten years ago the Department spent about £2,000 on the introduction into the country of the cultivation of durum Wheat. This variety of Wheat is especially suitable for growing in districts where the rainfall is slight. At the present time the annual value of the durum Wheat crop of the States is about £6,000,000.

CRATÆGUS IN MISSOURI.—Dr. C. S. SARGENT has just published another of his important monographs on the distribution of species of *Cratægus*. The present paper, which is printed in advance from the 19th Annual Report of the Missouri Botanical Garden, is devoted to the species that occur in that State. The author regards this instalment as a preliminary study, since the area of the State has not as yet been by any means completely explored, as far as this genus is concerned, and it is evident that many other species remain to be discovered. The results of Professor SARGENT'S work are very striking, for of the species described nearly all are as yet unknown beyond the State boundaries, although doubtless, as further knowledge accumulates, the proportion of purely endemic forms may diminish. The *Crus-galli* group, with 37 endemic species, is the largest in point of numbers, whilst the *Vivides* also form a somewhat large contingent, in which, however, the proportion of endemic species is rather smaller. An interesting point in distribution is the comparative absence of the *Tomentoseæ* group (13 species), though members of it form important constituents of the *Cratægus* vegetation of neighbouring territories. The memoir contains descriptions of a considerable number of new species, and, needless to add, it forms a very important addition to the literature of this interesting genus.

FRENCH AGRICULTURISTS IN ESSEX.—Our French friends are paying much attention to English agriculture. We learn from the *Essex County Chronicle* of July 24 that, on Thursday, the 23rd ult., a party of 30 agriculturists, headed by M. JOURDAIN, Professor of Agriculture in the School of Somme, visited the seed farms of Messrs. J. K. KING & SONS, in the Coggeshall district. The party inspected at the seed farm at Purley a splendid crop of Globe Mammoths that excited their admiration. There were extensive trials of pedigree Wheats, numbering 75 varieties, and of Oats and Barley, 47 varieties. At Robin's Bridge Farm crops of Peas were inspected, of which 205 different lots were observed. The collection of Sweet Peas included 164 varieties. Afterwards visits were made to Oak Farm, Hill Farm, and Hazell's Farm.

THE SOCIETY OF AMERICAN FLORISTS.—The dual convention of the Society of American Florists and the Canadian Horticultural Association this year will be an interesting event. Held at Niagara Falls, New York, and Niagara Falls, Ontario, respectively, at the same dates in the middle of August, there will be fraternal visits between the two societies, while the popularity of Niagara Falls will ensure a very large attendance from both sides of the line.

HOPS.—A report issued by the Board of Agriculture and Fisheries states that in Kent the crop is reported to promise well in all districts, though the bine has suffered somewhat from cold nights. There is at present very little vermin, and in most parts not much washing has been necessary; mould is said to be troublesome in some gardens. In Hants Hops are looking well, and over the greater part of the Hop area no washing has been required. In Sussex the prospects from the present appearance of the bine are favourable. In Surrey Hops are strong in bine, and so far promise well. In Worcester the bine is fair, but washing to destroy aphid has been general. In Hereford the prospects are reported to be good; the bine is vigorous and of good colour; washing has been necessary in a few plantations only. In Salop the crop is reported to be looking well.

FRUIT PRESERVED IN BRINE.—According to a Report by the British Consul at Naples, a new agricultural product, which has reached very important proportions as an export, consists of Cherries preserved in the following manner. They are first placed in the fumes of sulphur and then packed in casks with very strong brine. The chief place of export is to the United States, where, as they pay no duty, they compete with the home-grown fruit. On arrival the fruit is sorted out, the best being sold for the purpose of flavouring some of the various stimulants which, under different names, form the speciality of American bars, the second best are preserved in brandy in the usual way, and the remainder are used for the general purposes of confectionery. The extraordinary expansion of the trade may be judged by the following figures:—1904, £2,783; 1906, £14,584; 1907, £30,125. The figures for 1905 are not available, as the export of Cherries was in that year not placed under a separate head in the returns, but it will be observed that the increase in 1907 over 1906 was more than 100 per cent.

leaves which turn a brilliant red in the autumn. The seed pods are seen in abundance on the small branches of the tree, and contain three seeds about the size of a coffee bean, greyish-white in colour. As the autumn advances the pods dry up, exposing a cluster of three seeds. These are picked during November, and at once stemmed and made ready for use. They are steamed, and the white exterior of the seed, which is the vegetable tallow, or "Piyu," is thus removed. A small brown seed remains, which is ground in the Chinese millstone, boiled, made into cakes, and placed in a press, and a light brown oil extracted from the kernel. This oil is known as "Tze-yiu" or vegetable tallow-seed oil, and is used by the natives as a burning oil, and also for adulterating other more valuable oils. The refuse is used as a fertilizer. The tallow is collected, melted, and put into large tubs, which serve as a mould. Blocks of wood are put into each cake, to which ropes are attached and serve as handles. In this form it is brought to the market at Hankow. The seeds, as first picked, yield in weight about 28 per cent.

by the addition of water and other oils, and most of the Hankow shippers have found it necessary to remelt all the tallow in the presence of the native seller, and so remove any foreign matter. During 1905, according to the Customs returns, 20,000,000 lbs. were exported from Hankow, while in 1906 the amount increased to 27,000,000 lbs. Up to November 15, 1907, nearly 27,000,000 lbs. had been exported. *Journal of the Royal Society of Arts.*

INTRODUCTION OF PLANTS INTO UGANDA.—All plants which are introduced into Uganda for purposes other than for food are required to be fumigated before admission into the territory. They are only allowed to be imported at certain places appointed by the Governor, and arrangements for the fumigation are made there. The disinfection is conducted at the risk of the owner, and no compensation is given for any damage that may arise in consequence of the operation. *Der Handelsgeizner.*

CARPENTERIA CALIFORNICA.

This beautiful flowering shrub is not hardy in all parts of this country, but in favoured localities it will survive the winter and flower well in the open, when it forms a pleasing addition to the more common subjects in the garden. The photograph from which our picture was reproduced was sent us by Mrs. Dukinfield Scott, who states that several plants weathered last winter in her garden at Oakley, Hants, without showing any signs of damage.

NOTES FROM A "FRENCH" GARDEN.

SINCE we replaced the lights on the Melons the plants have grown more freely, but, unfortunately, in a few cases, the fruits which were hardened by the cold, are cracking. The last batch of Melons, planted at the end of June, have greatly improved, since in place of the cloches, we put frames and lights over them. In this batch of plants we have selected the first fruits which appeared; as later ones might not have time to come to maturity. We have found that to grow Melons under cloches, as is the custom round Paris, is impracticable here, unless at about the beginning of July we are able to use the frames and lights from the earlier batch of Melons. The system may be successful in a well-sheltered garden, though the cold nights at the end of June are very detrimental to their growth.

The chief work now is to plant Endive Batavian Green, which forms an important winter crop. At present, we are planting the last batch of Cauliflowers among the Endive, or by themselves in well-prepared ground in which Spinach will be a catch crop. We are preparing the ground for the last batch of Batavian Green and Autumn Spinach. All available ground is well dug and heavily manured for the main batch of Spinach and for the "Lamb Lettuce" (*Valeriana Locusta*), which will be sown in a fortnight's time.

All the outdoor crops planted early in July require watering, which, however, must be done judiciously in cases where the plants are not growing freely.

Many "marâchers" near Paris cultivate a piece of ground where there is no special water supply. Early in the season they plant an early batch of Potatoes "Hainault," a variety which has short foliage and even-sized tubers. Before clearing the Potatoes they plant Endive between the rows, and in August, after having hoed and levelled the ground, they sow between the salads a row of Spinach, which occupies the ground until the following spring. This plot is generally manured with the vegetable refuse from the ordinary garden, as it is the rule to clean all

FIG. 42.—*CARPENTERIA CALIFORNICA* FLOWERING IN THE GARDENS AT OAKLEY, HANTS; FLOWERS WHITE.

ENGLISH WALNUTS.—The English Walnut crop, says the *Globe*, will this year be a very heavy one. On one of the farms that last year won the King's Cup for root cultivation in East Berks, there are 41 large Walnut trees, the crops on which are heavier than have been the case for over a quarter of a century. On farms such as this the crop is usually sold by auction as it stands, the buyers having to gather them, and in years gone by over £100 has been obtained for the yield from these trees.

CHINESE VEGETABLE TALLOW.—The vegetable tallow tree, known to the local Chinese as the "Mu-Tze-Shu," is found in the mountainous and hilly sections of the province of Hankow. The trees grow in large numbers through the valleys in a semi-rocky soil, and on the mountain sides to an altitude of 2,500 feet. The tree, according to the American Consul at Hankow, is of medium size, with heart-shaped

of vegetable tallow, and about 40 per cent. "Tze-yiu." The vegetable tallow sells in the market at from 27s. 6d. to 30s. per "picul" of 133 lbs., and the vegetable tallow-seed oil at 25s. per "picul" of 133 lbs., very small quantities, however, of the latter oil being brought to Hankow, as none is exported. The vegetable tallow is used by the Chinese principally in the manufacture of candles, it being of greater consistency than the other oils used for the purpose, and only a small quantity of the white wax is needed. The vegetable tallow industry of Hankow is one of considerable extent, most of the tallow being shipped to Europe. None has been exported to the United States since the early part of 1906, and that consignment was made as a sample. The tallow is said to mix readily, and European firms find use for large quantities in the manufacture of soaps and candles. Great care must be exercised in buying it in Hankow, as much of it is adulterated

vegetables in the shed and never on the site where they were grown.

As the horticultural year starts in August, it may be interesting to give the quantities of seeds required in a "French" garden containing about 400 lights, 20,000 cloves, and two acres of ground.

Radishes, "Early French Breakfast, White Tipped," 1 peck of seeds. *Carrots*, "Early French, 1 lb.; Bellot, 1 lb. *Cos Lettuces*, Green of Paris, 4 ozs.; *White of Paris or Blonde Maréchère*, 4 ozs.; *Endive*, La Rouennaise, 4 ozs.; *La Ruffec*, 4 ozs. *Melons*, 1,500 seeds three years old. *On-heart Cabbage*, 4 ozs. *Cañiflowers*, 1 oz. *Celery Green*, $\frac{1}{2}$ oz. *Spinach Monstrous and Veroflax*, 1 peck. *Lamb Lettuce* (Green of Etampes), 2 ozs. *Cabbage Lettuce*, Little Black Gott, 4 ozs.; *Passion*, 4 ozs. *Paul Aquatics*, *Mayland*, *Essex*, July 27.

BALDEBSBY PARK, THIRSK.

This fine Yorkshire domain was in former years in the possession of the Devonshire family, from whom it was purchased by Mr. Hudson, a great railway magnate. From Mr. Hudson it passed into the possession of Lord Downes: the present owner, John Brennand, Esq., bought it from this nobleman six years ago. The estate is a distance of about five miles from the town of Thirsk and the same number of miles from Ripon.

The front of the residence is built in the Elizabethan style of architecture of stone obtained from a local quarry. It is believed that it occupies the site of a much older building, for traces of a former habitation have been found in the course of recent alterations necessitated, unfortunately, by a fire which destroyed much of the mansion three months after the present owner obtained possession.

The main front faces south, and at either end of the front of the building are two small Italian gardens with fountains.

The walls of the mansion are clothed with large specimens of *Ampelopsis Veitchii*.

On the west side is a lawn, to the north of which are two large beds planted with *Roses*, and in front of these are three large flower-beds, at the present time planted with *Lobelia cardinalis*, *Lobelia compacta*, Mrs. Chibran, *Alonsoa incisifolia*, and *Blue Ageratum*.

There is also a sunken garden surrounded by balustrades in stonework. There are beds in this sunken garden, some of which are filled with *Violas* and *Begonias*, the centre beds being permanently planted with *Roses*. There is also another sunken garden further from the Hall that forms a fine feature. A series of terrace banks form the boundary on the Park side, the top being planted with *Penzance Biars* and other rambling *Roses*, which give a fine touch of colour to the landscape in summer time. The boundary on the side nearest the house is formed by a solid stone wall having a balustrading on its summit: against this wall are planted *Roses* and *Ampelopsis*, and although this garden has not been made more than three years, the plants have already made considerable growth, and promise soon to entirely cover the stonework. There are two long oblong flower-beds in this sunken garden, planted with *Begonias* and *Nemesia strumosa*.

Leading in a westerly direction is a path that approaches a spot known as the children's playground. Some fine old shrubs form a suitable background to a long ribbon border. This is planted with *Blue Violas*, *Pelargoniums* Flower of Spring and *Paul Crampel*, white *Anemones*, the golden variety of *Pelargonium Harry Hoover*, &c.

At the back of the mansion is a long walk that leads to the River Swale. By the side of the path is a border of shrubs, amongst which are many choice varieties of *Rhododendrons*. By the river is a magnificent specimen of the

copper-coloured *Beech*, and other trees have recently been removed in order that a view of this fine tree may be the better obtained. On the east side of the building is a tennis lawn, surrounded by a shrubbery and several flower-beds. Two of these beds are planted with *Pelargonium Henry Jacoby*, and *Stocks*: the largest bed is filled with *Roses*. Before we leave this portion of Baldersby Park, mention must be made of a path $\frac{1}{2}$ miles in length that is bordered on one side by shrubs and on the other by herbaceous plants backed by a line of shrubs. *Delphiniums* and *Foxgloves* are intermingled with the shrubs, whilst the flower-border contains plants of perennial species that furnish a succession of flowers.

The park in front of the residence contains some very large Oak trees: an old veteran that has lost its top has a girth of 42 feet at a distance of 3 feet from the ground. The trunk is hollow, and as many as 11 persons have partaken of tea at the same time within the cavity. The stem is now bound with iron bands. These old Oaks are said to be remains of the ancient forest which existed at this part. A tree still in perfect condition measures 37 feet

divided into six compartments, all, save the conservatory-like central division, being devoted to the culture of fruit. The structure is built on the wire tension system, and in consequence the interior is very light, there being no obstructing rafters. At the eastern end a partition separates an early and a late Peach house, the latter being the first entered. It is planted with *Barrington*, *Sea Eagle*, *Crimson Galande*, *Golden Eagle*, *Dymond*, *Stirling Castle*, and *Royal George Peaches*, and *Humboldt*, *Stanwick Fringe*, *Pineapple*, *Lord Napier*, and *Dryden Nectarines*, which represent an admirable selection. The early house is planted with *Grosse Mignonne*, *Early Rivers*, *Royal George*, and *Peregrine Peaches*, while of *Nectarines* there are *Cardinal*, *Violette Hâtive*, *Lord Napier*, and *Downton*. Opening from the early Peach house is a structure built on the other side of the wall, and therefore facing north, that is devoted to the culture of cool *Orchids*. A pretty feature is the Fern-covered wall, the plants—*Adiantums*—being planted in a compost held in position by wire netting. The next division is the conservatory to which reference has already been made. It accommodates several ornamental-leaved plants, including very large and healthy

FIG. 43.—BALDEBSBY PARK, NEAR THIRSK, THE RESIDENCE OF JOHN BRENNAND, ESQ.

round at 3 feet from the ground. The park also contains some very large *Beeches* and *Sequoia* (*Wellingtonia*) *gigantea*. There is a lake in the park, in which are two crescent-shaped islands planted with shrubs and bulbous plants. Near the lake is an obelisk, the history of which is not known, but it is of great age. There is another similar monument near to the home farm. A cricket ground and a recently-built pavilion are for the use of the employees on the estate.

The pleasure gardens and grounds at Baldersby are extensive and well adorned with flower-beds and borders, the fine old park, with its noble trees, giving dignity to the surroundings. But, fine as these are, the chief attraction of this estate to the gardener lies in the splendid walled-in kitchen garden and the ranges of glass-houses therein. This garden has an area of more than four acres and is divided into eight square portions by paths, and there is a path 6 feet in width all around it, separated from a path by a border of perennial plants. On the north side of the garden is a continuous range of fruit houses, 118 yards in length. It is

specimens of *Cycas revoluta* and *Encephalartos*, also *Livistona chinensis* and *Kentia Forsteriana* and *Belmoreana*. The wall is covered with tile "pockets" that are planted with varieties of *Begonia Rex*, *Hoya carnosae*, and *Ferns*, the whole having a charming appearance. The next house or division is devoted to *Pears*, with late-fruited *Peaches* and *Nectarines* against the wall. This opens into a structure devoted to the culture of *Plums*, where choice varieties of this stone fruit are grown. The wall at this spot was covered with a remarkable *Pear* tree when the house was built, and it was allowed to remain. It bears no fewer than 22 distinct varieties, and many of the grafts were freely fruited when we saw it. The last division is 47 yards long and 5 yards wide; many of the trees, including *Apple*, *Pear*, *Plum*, and *Cherry*, are in pots, the majority being freely fruited.

Facing this fine fruit range are the bathes and potting shed. The young gardeners' apartments contain a properly-appointed kitchen, a sitting-room, and bath-room, in addition to the bedrooms, &c. The south wall of the

bothies and potting shed have against it lean-to vineries, including early, mid-season, and late houses. In front is a row of heated frames. What may be termed the main block of plant-houses is now reached. It comprises seven modern glass-houses, all in the best possible condition and with the latest improvements in plant structures; the largest houses are 50 feet in length. The whole block is heated with three "Trentham" boilers; the stake-house at the back a tunnel which holds about 20 tons of fuel. The ground about the glass-houses outside is covered with concrete, which enables the place to be kept in trim order.

The first house, on the west, is divided into a vinery and two Peach houses. One of these latter divisions is planted with trees of the late-fruited Golden Eagle and Sea Eagle varieties. We also noticed in this house well-grown plants of *Hydrangea Hortensis* and its variety *Marisii*. The next division is an early Peach house, the variety group being Royal George, with *Violette Hâtive Nectarine*. The vinery was planted last year with young vines, and until the canes furnish the structure it is used for pot trees of Apples, including Lady Sudeley and Beauty of Bath; also Pears Brockworth Park and Pitmanston Duchess. The next house is devoted to Carnations. It is in two sections; one contains varieties of true Carnations, and others of the water-flowering type, including Duchess of Portland, which is a reliable kind at Baldersby, being free in flowering and of good quality; others which do well are Britannia, Robert Craig, Floriana, Enchantress, Lady Bountiful, and Nelson Fisher; the other compartment contains Carnations of the *Souvenir de la Malmaison* type, in all of the best kinds. The plants were in vigorous growth and gave promise of an abundance of flowers. The next is a Melon house in two divisions, but only one had a crop of these plants, and of these had recently been planted. The other part was cropped with Tomatos, the variety being Brotherston's Al, a Tomato that does well in Yorkshire, it being largely in evidence at the recent Yorkshire Gala, where it was awarded all the premier prizes offered for this fruit. The next house is divided into two compartments, one being a propagating house; the other containing Melons, the varieties favoured being Hero of Lockinge, Gunton Scarlet, and a seedling, the rest of the Lord Derby and Frogmore Orange. Number 5 house is a similar structure to the last-named, the first compartment being used for the culture of *Codæums* (*Crotons*) and *Dracænas*, the other is planted with Melons. The next plant-house has three divisions; two are filled with Orchids, the other with border Carnations in variety, including Sir Richard Samuelson, Francis Samuelson, Alceste, Uriah Pike, Helmsman, and Sir R. Buller. No fewer than 3,000 plants of Carnations are cultivated. One of the Orchard houses is a *Cattleya* house, with *C. gignis*, *C. Mendelii*, &c., all in good health; the other has, besides *Cattleyas*, plants of *Dendrobium*, *Calanthe*, and *Cypripedium*. Some fine specimens of *Dendrobium Wardianum* were noticed. The first division of the next house is utilised as a plant stove, some of the inmates being *Vandas* in variety, *Caladiums*, a good strain of *Streptocarpus*, *Begonia Gloire de Lorraine*, *Dracæna Victoria* and *Pandanus Veitchii*. The other division was filled with greenhouse flowering plants, such as *Calceolarias*, *Belconiums*, *Astilbes* (*Spiræas*), including the new pink-flowering varieties; *Hippastrums*, *Marguerites*, *Liliums*, &c. This house is always gay with flowers, and in summer time the roof is covered with *Bougainvillea*, *Abutilon*, *Solanum jasminoides*, *Streptosolen Jamesonii*, *Tacsonia exoniensis*, and *Passiflora*, whilst hanging baskets have trailing sprays of *Asparagus Sprengeri*.

Against the walls surrounding the kitchen garden are planted fruit trees, the top of the wall having a glass coping, and 2 feet of the glass can be removed, if need be, in the summer months. Close to the long range of glass-houses is planted against this wall a tree of King of Tompkins' County Apple. It has an especially favoured spot, and so fine are the Apples produced by this tree that they might easily be mistaken for orchard-house fruit; indeed, Apples from this tree are said to have been disqualified at the autumn fruit show of the Royal Horticultural Society, the judges supposing

them to be grown indoors. Other fruit trees trained on this wall are Pears: Pitmanston Duchess, Doyenné du Commerce, Beurre Superfin, Doyenné Boussoch, Clapp's Favourite, Margaret Marillat, Souvenir du Congrès, Triomphe de Marie, Marie Louise d'Uclée, Louise Bonne de Jersey, Marie Louise, and Victoria. Plums: King's Cole's Golden Drop, Monarch, Bravants's Gage, Pond's Seedling, Grand Duke, Count Althann's Gage, and Jefferson. Against the north walls are Morello Cherries, Gooseberries, and Currants. This latter fruit has been available for the past two seasons as late as Christmas. There are good crops of all kinds of vegetables, the soil being a rich loam overlying clay, beneath which is sand and gravel.

The fruit room has double walls and two roofs, the floor being of concrete. This structure has, in all weathers, an equable temperature, and is admirably adapted for its purpose. Near the gardener's house, which is a fine building adjoining the public roadway, is a scroll bed, having a row of *Lobelia compacta* var. Mrs. Cibbran, *Echeveria*, *Pelargonium Flower of Spring*, and in the bays scarlet-flowered *Begonias*, the back portion being furnished with *Tageetas* and *Begonias*. The gardens and grounds are in the care of Mr. J. E. Hathaway, who is to be congratulated upon their excellent appearance, and especially upon his skill as a plant and fruit cultivator.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

NEED FOR A TRIAL OF EARLY TRUMPET DAFODILS.—There is need for a trial of early sorts of *Narcissus* of such varieties as can be had in flower in mid-winter, by gentle forcing under glass. I am willing to send my moiety in yellow trumpet kinds because, after all, a good winter flowering trumpet *Dafodil* that may not find favour with a *Narcissus* committee in April, may at Christmas fetch 4d. or 6d. each bloom in the west end of London. There is much more money in the early bloom than in the April one at a glut. I am sure it is not unreasonable to ask for this trial, which could be conducted in the R. H. S. gardens at Wisley. There should also be got together for trial all the popular market sorts from different parts, such as *Horsfieldii*, *Sir Watkin*, *Emperor*, &c. They should be potted up, to compare the difference between bulbs obtained from districts south of London, also from north and south Ireland, from north and south England, and from the Channel and Scilly Isles, in order to note the difference in green bulbs from Holland and bulbs from the United Kingdom. For instance, I have myself had experience of *N. Horsfieldii*, by putting some big soft bulbs in size proportionate enough to produce two or three blooms, as against medium-sized hard, well-ripened ones. The result was that the latter bulbs came into flower fully ten days earlier than the other, each one giving two to three blooms, while the former that were earlier grown only gave single blooms. *Wm. Bayler Hartland, Aid Carrn, Cork.*

THE CONDITION OF BURNHAM BEECHES.—With all due respect to the members of the committee who recently reported on the condition of the old Pollards in Burnham Beeches, I think they have overlooked the true cause of the decay and death of so many of these trees during the last few years, and the obvious fact of the remainder. The report suggests that the felted scale (*Cryptococcus laui*) alone is the indirect (if not direct) cause of the bad health into which such a large number of trees have fallen. Possibly the scale may have hastened the decay of a few trees, but it has never yet been proved that this insect can lead to fatal results in an otherwise healthy tree. That Beech does occasionally die with the scale on their stems is true; but trees also die on which no scale can be found, and I am not aware that any figures exist to show that the mortality amongst scale-infested trees is greater than amongst those which are free from the pest, although the latter undoubtedly causes the death of patches of bark on which the woolly accumulations have been lying for many years. But the real cause of the decay of the old Beeches in question is more probably old age than anything else.

The normal life of a Beech tree seldom exceeds 300 years, and the average tree succumbs before it reaches 200 years, chiefly from stornis or parasitic fungi. The approximate age of the old Pollards in Burnham Beeches has never been estimated, and no sound remains in their butts enabling the annual rings to be counted; but the limbs and branches which were thrown out after their last pollarding show an age of over 200 years, as I have ascertained from windfalls, and it is obvious that the original stems are much older, probably as old again at the very least. The process of pollarding undoubtedly lengthened their lives, by decreasing the effect which stornis exert upon taller trees; but even so, a time must come when natural decay will assert itself, and there is little doubt that that time has arrived, and that these trees have been gradually disappearing for many years, and the general condition differs very little from what it was 20 years ago. Whether anything can be done to prolong the lives of the more interesting specimens is doubtful, but there is little doubt that those standing on what is known as "the plain" suffer from the treading and hardening of the ground during the summer months, when visitors and picnic parties are most numerous. Mulching and artificial manuring suggest themselves as the most promising measures for arresting their decay, and these remedies should be particularly useful on the drier and poorer part of the wood where assistance is most needed. *A. C. Forbes.*

DETERIORATION OF STOCK.—It is not an uncommon occurrence to find that men who are admittedly good gardeners, experience great difficulty in growing good plants from stock which has been in their possession for a considerable time. That this is not due to want of attention or skill on their part could be proved, but the fact is that, despite the good attention, the plants are not capable of building up a robust constitution. This is due in most cases to deterioration of stock consequent on propagating from plants which have been unduly forced into growth and luxuriance by liberal feeding. I could cite instances of Potatoes, Onions, *Salvias*, *Chrysanthemums*, *Begonias*, and other plants, which, owing to repeated propagation from the same stock, not only lack vigour, but show also a tendency to lowered regenerative capacity. The case of *Chrysanthemums* may be cited. These are, in the ordinary methods of cultivation for the production of large blooms, subjected to gross feeding, with the result that the wood becomes hard, the plants refuse to throw up useful basal cuttings or produce fasciated growths that are unsuitable for the purpose. The result is that cuttings are chosen, and the old plants, resulting from stem cuttings are always slow to produce basal shoots. Thus, year by year the cuttings become more difficult to get and difficult to strike. Is it any wonder, then, that being rushed along in heat, and perhaps hardened off quickly, they should not only lose vigour, but likewise the power of regaining vigour by the absorption and assimilation of plant food? The floral results then prove disappointing. That this occurs greatly as a result of liberal feeding I have no doubt, for I can recall a case where gross feeding was discontinued for the specific purpose of regaining vigour in the stock, and the result was that in the following season good, useful cuttings were thrown up from the base of the plant in greater profusion than had been known for years. It is a well-recognised fact that vegetables deteriorate if grown continuously on the same ground, and the obtention of this by a rotation of crops is well-nigh universal. The Potato requires change of soil as well as of site, and the benefit of changing sets with other

now often acted upon. It is recognised that liberal feeding is essential to success as judged by size, but when we know that this feeding weakens the constitution we must find some means of renewing the vigour which has been lost. Happily means are near at hand. We should keep plants especially for stock. Grow them well, give them ample room, good soil, sufficient sunshine, careful watering, and grow them in a natural manner without subjecting them to the high feeding given to other plants. This may be done in the case of Chrysanthemums by striking cuttings in the usual way and afterwards growing them outside. If earlier cuttings are

the selection of cuttings. Where they know deterioration to have set in, they should grow plants especially for stock purposes, and no condition should they allow the propagation to be carried out by an inexperienced man. Moreover, they should see that plants obtain a fair start from the cutting or seed stages onward, so that there is no need to hurry them along under unnatural conditions, for time lost cannot be regained even in plant culture. The importance of vigour in stock cannot be too strongly insisted on, for greater vigour means greater immunity from the ravages of pests and from the harmful effects of bad weather. The stronger the

old, when they betray their origin by sending up numerous leaders, or else assume the character of a branch stuck in the ground. There is really no excuse for dealing thus with a tree so easily raised from seed as Sciadopitys. *F. M.* speaks of the seeds as being "comparatively dear"; but the price quoted for them in *J. Kafu's* catalogue this year—18s. per kilo (= 2 lb.) and 1s. 6d. per 100 grammes (= 3½ oz.)—seems to me comparatively cheap. *Herbert Maxwell, Moorville.*

—The note by *F. M.* on p. 81 of our last issue on a method of propagating the Umbrella Pine of Japan recalls a very interesting statement made to me some years ago by the late Mr. Hermann Herbst, of Richmond. Before commencing business on his own account, Mr. Herbst was for some time propagator to the late Mr. John Standish, of Ascot, who received the plant from Mr. Robert Fortune about the same time (1861) as it was sent home to his firm by Mr. John Gould Veitch, and, as all who knew Mr. Herbst were aware, he was not only a clever propagator, but a skilled plant grower as well, so that a conversation with him was always interesting, and often very instructive. Walking round his houses with him one day and talking about plants difficult to increase readily, he told me of a "happy hit" which he had made with the Sciadopitys soon after it was put into commerce by the Messrs. Veitch. I do not remember the time of year when he obtained his stock, but that hardly matters so much as the point of his statement, which was simply this:—Early in the following January he put the plants into strong heat, and rooted the young, succulent shoots as soon as they were large enough to handle. He stated that they rooted very readily, and that in this way he soon obtained a larger stock of plants than was possessed by the Messrs. Veitch. I have never had an opportunity of putting this method to the test. *Senex.*

FIG. 44.—STANHOPEA Oculata AS IT FLOWERED IN THE COLLECTION AT KEW GARDENS LAST SEASON: FLOWERS LEMON-COLOURED WITH LILAC SPOTS.

(Photograph by C. F. Raffill.)

desired they may be taken up and potted or plunged in some cool house. I feel confident that this plan would impart vigour to the stock. In the case of Strawberries, healthy runners could be chosen and planted out, pulling off any fruit that forms and reducing the number of runners to four or five. I have known plants received from a neighbour's garden do better than the general stock, although there had been no apparent difference at the start. This I ascribe to the change of condition, for no two men grow plants exactly alike, and plants seem to like a change. Gardeners should be more careful in

plant the more readily will it respond to good treatment. *William F. Rowles.*

SCIADOPYTIS VERTICILLATA.—Similar advice to that given on p. 81 upon the propagation of this interesting Conifer appeared in the *Field* some months ago, and I felt bound at the time to enter a protest against what I considered mischievous advice. Planters have suffered too much in the past from being supplied with Conifers propagated from grafts or cuttings (especially those of the Cypress group). The evil is not apparent until the trees are several years

ONOCYCLUS IRISES AND COLD STORAGE.—

In continuation of my note in your issue of June 20, and in answer to Mr. Jenkins' enquiries on p. 32 (July 11), may I add that the rhizomes with which I experimented were newly-imported roots of such kinds as *Lortetii*, *lupina*, *atropurpurea*, and *Bismarckiana*. I only packed up a rhizome of two of each, and hardly expected any flowers. However, the first to flower was *lupina*, which bloomed on May 31, followed by two more flowers of this species, and one each of *atropurpurea* and *nigricans*. The flowers were certainly somewhat small and the foliage slender, and I therefore intend another year to plant the rhizomes about a fortnight or so earlier; that is, about the middle of February, unless the weather is too unfavourable. At present (July 14) the plants are growing vigorously, and I shall endeavour to ripen them off with the aid of glass as soon as they show signs of going to rest. I shall then hope to be able to lift good healthy roots, somewhat more acclimatised to their present surroundings than when they arrived from the East last August. *W. R. Dykes.*

IRIS NEPALENSIS.—This Iris is a curiosity in more ways than one. In the first place its root-stock is unlike that of any other Iris, consisting of a bud in a sheath of remains of old leaves, from which depend persistent roots like those of a Juno Iris. Coming from Nepal, it requires abundant moisture in summer and dry conditions in winter. Last autumn, when the leaves withered, I lifted the root in a mass of soil and dried it off, without disturbing it by shaking it out of the earth. I replanted it in peat and leaf-soil at the beginning of March. The leaves appeared on May 30 and the first flower on July 9, followed by a second from the same spathe five days later. The individual flower only lasts a few hours, is extremely delicate in texture and of a pale lavender shade. *W. R. Dykes.*

THE MEETING OF ROYAL HORTICULTURAL SOCIETY ON TUESDAY LAST.—This meeting was a striking instance of the little value that attaches to horticultural exhibitions in cases of a holiday immediately following a Bank Holiday. So-hum, indeed, has the attendance at these shows been less satisfactory. *Fellow.*

SOCIETIES.

ROYAL HORTICULTURAL.

August 4.—A meeting of the Committees was held on this date. The exhibition was very small, and visitors were extremely few, doubtless owing to the show being held on a day following the most popular Bank Holiday of the year.

Several novelties were presented to the Floral Committee, who granted two Awards of Merit, and the Orchid Committee one First-Class Certificate, one Award of Merit, and one Botanical Certificate.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. H. B. May, Jas. H. Walker, E. H. Jenkins, T. W. Turner, E. J. Bowles, W. Howe, J. Douglas, R. Hooper Pearson, H. J. Jones, Chas. Dixon, G. Reuthe, J. T. Bennett-Poe, Chas. E. Shea, Chas. E. Pearson, and W. P. Thompson.

A group of Phlox decussata in variety was shown by Messrs. P. S. WARR, Ltd., Ware's Nursery, Feltham, Middlesex. They were remarkably good spikes of bloom, one of the varieties being a fine white flower of recent introduction. It was labelled *Freiifraulein von Lassburg*. There were also seen the lovely Coquelicot, Flambeau, Espérance, Lady Najier, Miss Pemberton, Leonard di Vinci, and others. (Silver Banksian Medal.)

Messrs. KELWAY & SON, Langport, Somerset, displayed about 100 varieties of their strain of Gladioli. Amongst such varied and beautiful kinds it is difficult to enumerate all of merit, but we may select Langport White, Lady Rachael Bruce (yellow, with deeper-coloured lip), Baden-Powell (salmon-red, with yellow blotch), Wolfe, Ian Kelway (mauve, with a red mark on the lower petals), Lord Errol, Hush Beauty (rose, with a yellow lip), Lago, and Lord Courtney (a distinct rose-coloured flower, with a white stripe on the petals and a white lip). (Silver-Gilt Banksian Medal.)

Messrs. WEBB & BRANT, nurserymen, Salton Walden, showed double-flowered Hollyhocks in variety. They had spikes of flowers at the back, and in a setting of ordinary Asparagus foliage, round baskets with single blooms set in mossy Saxifrage. All the varieties were of merit, the blooms being richly coloured and very much doubled, so that each appeared like a big rosette. The best, with their colours, are as follows:—Apple Blossom (pink), Miss Lizzy King (yellow), alba superba (white), exceptionally fine), Venus (salmon), Mrs. Carl Meyer (a very delicate pink shade), Walden Primrose (yellow), Luna (creamy yellow), and Black Knight Improved (maroon). (Silver Flora Medal.)

Messrs. H. B. MAY & SONS, Upper Edmonston, filled a large table with flowering plants and Ferns. They showed batches of Campanula isophylla in white and blue varieties, a group of Lapaerias in both red and white varieties, and a large batch of Ixoras, as small pot plants, all freely flowered. (Silver Flora Medal.)

Messrs. JOHN K. KING & SONS, Cogge-hall, Essex, showed a pretty exhibit of Sweet Peas. (Silver Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, W., showed 14 varieties of Eucalyptus in small pots, the plants having been raised from seeds sown in January last. The species included *E. ficifolia*, *E. Globulus*, *E. citriodora*, *E. rostrata*, *E. occidentalis*, *E. calophylla*, *E. amygdalina*, *E. erythronema*, *E. Gunnii*, *E. botryoides*, *E. cordata*, *E. urnigera*, and *E. coccinea*.

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, displayed boxes of Dahlias, both Cactus and single-flowered varieties, against a background of hardy flowers in vases. The garden flowers embraced Lupinus, Dracocephalum virginicum, Helenium, Spiraea, Centaurea fistulifolia, herbaceous Phloxes, Chrysanthemum maximum, &c. (Bronze Banksian Medal.)

Mr. GEO. REUTHE, hardy plant specialist, Keston, Kent, showed a selection of hardy plants in flower. There were also many sprays of flowering shrubs, including the fragrant Magnolia fissata, Rhododendron camelliflorum,

Desfontainea spiosa, Berberidopsis corallina, Eubothrium coccineum, Buddleia variabilis var. Veitchiana, and Paliurus aculeatus.

Messrs. WM. BULL & SONS, King's Road, Chelsea, showed Caladiums as small plants bedded in pans, with moss. At the back was a row of Arabas.

A few vases of border Carnations were staged by W. A. WATTS, Esq., Bronyvilla, St. Asaph, N. Wales. Mr. W. DEAL, Kelvedon, showed a variety of Iberis labelled Snow Queen. Vases of flowers of Buddleia variabilis var. magnifica, with a number of spikes of Agapanthus umbellatus were shown by Messrs. HUGH LOW & CO., Bush Hill Park, Enfield. Two pretty Antirrhinums were shown by Messrs. DUBBIE & CO., Rothsay, N.B., and Mark's Tey, in Moonlight and Brilliant. Both are shades of carmine, the former being also heavily marked with yellow.

AWARDS OF MERIT.

Rose Paula.—A dwarf-habited Tea variety, in flower greatly resembling Marchal Niel, but with shorter petals. The blooms are very pretty in the bud stage. Grown for bedding purposes, the plants are generally about 18 inches high. Shown by Messrs. PAUL & SON, Cheshunt.

Carnation Countess of Pembroke.—A border variety of good form, the flowers being almost white, but slightly suffused with rose. Shown by Mr. T. CHALLIS, Wilton House Gardens, near Salisbury.

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), de B. Crawshaw, J. Wilson Potter, R. G. Thwaites, A. McBean, H. A. Tracy, W. H. White, W. Boxall, and H. Little.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Flora Medal for a very interesting group, the best novelty in which was the handsome *Vanilla amena* var. *Sanderae*, which received an Award of Merit. The pretty *Laela monophylla* was represented by a fine specimen with nine orange-scarlet flowers, and among other rare and attractive species were *Galeandria lacustris*, *Epidendrum campylostachy*, the curious, green-flowered *E. rigidum*, a dwarf form of *Eria acervata*, the rare *Dendrobium bellatulum*, *Physisiphon Loddigesii*, *Sarcanthus Williamsonii*, *Pescatorea cernia*, a batch of *Cypripedium Godefreyi leucochilum*, *Lycaste leucantha*, &c. Of hybrids noted were several *Cypripedium Rothschildianum* crosses, (C. Mrs. de grande × *Rothschildianum*) being a very distinct and fine form.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, secured a Silver Flora Medal for a good group, in which the hybrids of C. Rothschildianum were finely shown, the C. callo-Rothschildianum Orchidhurst variety, being a noble plant, with two spikes of flowers, in which both the parents were clearly indicated; the broadly-extended petals, blotched with chocolate-purple, well distinguishes it from other varieties of this cross. C. Bella, Westfield variety, a very pretty and graceful hybrid; C. Patrocinii (Mastersiana × *Goverianium*), a large flower of fine substance; C. glaucophyllum, C. niveum, C. vexillarium, and an interesting cross between C. vexillarium and C. Argus; a fine form of C. Maudie; two examples of *Bulbophyllum Godeffianum*, *Cattleya Warscewiczii*, *Sanderiana*, and *Platypleura filiformis*, with a number of its graceful flower-spikes.

Mons. MERCIENS, Mont St. Amand, Ghent, was awarded a Silver Banksian Medal for a small group, including two forms of *Odontoglossum amabile*, a good, large-flowered *O. percutum*, *O. Wiganianum*, and a very effective white-flowered *Odontoglossum*, spotted with deep claret colour, supposed to be a cross between *O. Hallii* and *O. ardensimum*.

H. S. GOVISON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), showed *Braudo-Cattleya* Plur. Fairlawn variety, and *Cattleya Atalanta* var. Goodsonie.

R. G. THWAITES, Esq., Chessington, Streatham (gr. Mr. J. M. Black), showed *Cattleya superba* alba, which had already received a First-Class Certificate; two plants of his new *Odontodia Thwaitesii*, *Odontoglossum Thwaitesii* (*Harrivannum* × *ardensimum*), and *Sophro-Cattleya Warmhamiensis* var. J. M. Black, which secured a First-Class Certificate. Mr. JAS. DOUGLAS, Great Boobham, sent a

curious little Orchid from tropical Africa, with white flowers.

Herr OTTO BEYRÖDT, Marienfelde, Berlin, showed *Cattleya Harold* var. Hildegard (*Gaskelliana* alba × *Warscewiczii* Frau Melanie Beyrödt), an attractive white flower with rosy-mauve front to the lip.

AWARDS.

FIRST-CLASS CERTIFICATE.

Sophro-Cattleya Warmhamiensis var. J. M. Black (C. *antioquiensis* × *S. grandiflora*), from R. G. THWAITES, Esq., Chessington, Christchurch Road, Streatham (gr. Mr. J. M. Black). A charming dwarf Orchid with a comparatively large, deep crimson flower having a claret shade, and much darker than the original form. The disc of the lip is yellow, the side lobes are streaked with red, and the front is ruby red.

AWARD OF MERIT.

Vanilla amena var. *Sanderae* (*Roxburghii* × *cardalis*), from Messrs. SANDER & SONS, St. Albans. A very handsome and interesting natural hybrid, and probably the reverse cross of the original, the seed in this case coming from *V. cerulea*, and hence the larger and more handsome flower. The fine inflorescence bore many flowers, thick in texture, fine in shape, and with a cream-white ground colour, the veining being followed by a broad violet-coloured reticulation; the lip is violet in colour with a claret-coloured tinge; the apex has short, diverging lobes.

BOTANICAL CERTIFICATE.

Litostachys Hydrifera, from Sir TREVOR LAWRENCE, Bart., K.C.V.O., Burford (gr. Mr. W. H. White). A graceful species from Uganda. The decurved racemes each have several wax-like white flowers with pointed brown-tinted spurs.

CULTURAL COMMENDATION.

To Mr. G. G. Whitelegg (gr. to J. BRADSHAW, Esq., The Grange, Southgate), for *Lycaste tricolor* albens, with 29 pretty green and white flowers. The type was also shown well-bloomed. The species is most floriferous and compact in growth. It is a native of Guatemala. ▶

Fruit and Vegetable Committee.

Messrs. JAS. VEITCH & SONS, LTD., King's Road, Chelsea, showed a large collection of fruit trees in pots. There were Figs, Gooseberries, Plums, Peaches, Apples, and Pears; a well-fluted, and each was a goodly-shaped tree. The *Clare Plum* was carrying very large crops; Marquis of Downshire, Royal George, Prince of Wales, and Thos. Rivers Peaches were all good. A tree of the last-mentioned variety was exceptionally fine, and occupied a prominent place in the centre. Amongst the Apples we noticed good examples of Washington, Chas. Ross, and Gasconne's Scarlet; the best Pears were *Souvenir du Congrès* and *Dr. Jules Guyot*. The Figs represented most of the best kinds, and the Gooseberries were *Whinham's Industry*. (Silver-Gilt Banksian Medal.)

Messrs. JAMES CARTER & CO., 237 and 238, High Holborn, London, displayed about 50 varieties of Dwarf or French Beans. The plants had been lifted on the day of the show from the firm's trial grounds at Mortlake and placed in 7-inch pots. The collection embraced the ordinary, the stringless, and the wax-podded types, also many new seedlings as yet not in commerce. Varieties most freely cropped were *Golden Wax*, *Wandian Glory* of the stringless type, *Wythes' Early Gem*, *Longsword* a fine large pod, *Rifeman*, *Sion House* (later maturing than many of the others shown), *Seedling No. 249*, *Holborn Wonder* (stringless), *Leonard's Stringless*, and a Japanese variety labelled No. 66. (Silver Banksian Medal.)

Mrs. W. H. FLOWDEN, 167, Chapter Street, Westminster, staged a number of preserves, consisting of jams, jellies, and fruits preserved whole. They appeared very tempting. (Silver Knightian Medal.)

FRUIT AND VEGETABLE COMMITTEE AT WISLEY.

July 31.—A meeting of this body took place at Wisley, in the above date, under the chairmanship of Mr. A. H. Pearson, 10 other members being present. About 40 varieties of early Potatoes were inspected, several test roots of each

being lifted. In some cases the stocks were not true. The best roots lifted of all the stocks proved to be of that popular variety Sir John Llewellyn. Others especially good were Ringleader, Sharp's Express, and Victory, the first-named of these being good in samples from three diverse sources. Awards of Merit from the Midlothian Early, a well-known kidney variety, and to a very early, flatish, round variety named Courtene Seedling. This award was made specially because of its fitness for frame and pot culture, the haulm being very short. The stocks of Potatos were planted on April 7. The later varieties promise a heavy crop, and will be examined by the Committee in September. Parsley, of which there are numerous stocks, more or less diverse, each being represented by two rows, have generally done well. Several varieties were voted three marks. They will all be examined again, when the characteristics of each are fully developed, to test their distinctness. To one variety, Massey's Dwarf Curled, an Award of Merit was given, as, whilst so good, it was the most distinctly curled variety in the trial. Numerous stocks of round or turnip-rooted Beet were examined: some had very irregular tops; others had handsome roots, but badly-coloured flesh. An Award of Merit was given to Sutton's Crimson (John). A similar award was made to a dwarf French Bean temporarily named Seedling Dwarf. The variety is a marvellous cropper, and is specially good for early forcing and for outside borders. The stock was sent by Messrs. James Carter and Co. Later, several handsome Melons were tasted, but none merited an award. A few had a common defect: the outer half inch of flesh was hard, while the inner flesh was soft and pulpy.

The Committee also inspected the span-roofed vinery, where there is now fruiting probably the largest collection of Grapes in the kingdom. Many of the vines, though but two years planted, were carrying superb bunches. If the Council sanction the proposal, as it is hoped will be the case, some 40 distinct varieties of Grapes may be shown at Vincent Square a few weeks hence.

CRAWLEY & DISTRICT FLOWER SHOW.

JULY 22.—The fifth annual exhibition promoted by the Crawley and District Gardeners' Mutual Improvement Association took place on the above date in glorious weather at Heli Lodge, by the kind permission of Mr. E. J. Lehmann. In all respects the exhibition, both in regard to the horticultural and the industrial departments, was excellent, and the arrangements in connection with it were of a most complete and satisfying character. There was ample evidence of the growth and importance of the exhibition, and the non-competitive exhibits were a special feature. The entries showed a marked increase on previous years and the competitors in the horticultural section numbered 40.

ST. AUSTELL COTTAGE GARDENING.

JULY 28.—The sixty-first exhibition of this Society took place on the above date in the Market House. The show was remarkable not only for the large number of entries, but also for the high standard of the exhibits generally and of vegetables in particular. There were seven classes for Sweet Peas, for which 68 competitors entered. Mr. E. A. P. BROAD, of St. Blazey, won in the premier class for 18 distinct varieties.

Mr. C. A. HANSON, of Fovey, showed a well-grown bunch of Muscat of Alexandria Grapes, and this exhibitor won the 1st prize in the class for a collection of fruits.

Mr. W. H. HURCHES, of Trevarick (gr. Mr. Wright), secured the prize for 12 Carnations and Picotees. The same gentleman staged 150 plants of Carnations and Picotees not for competition.

Messrs. TUPLIN, Newton Abbot, displayed a trade exhibit of Carnations and hardy plants.

The need exists for a better place in which to hold the show so as to give more room for the inspection of the exhibits. Another matter for comment is that many of the exhibits are not labelled, and as a consequence the educational value of the show is in a great measure lost. H. W.

MIDLAND COUNTIES SWEET PEAS.

JULY 29.—The officers and workers responsible for the first show of this Society are to be congratulated upon the splendid exhibition of Sweet Peas held in the spacious Drill Hall, Wolverhampton, on the above date. The quality of the flowers was surprisingly good, especially of those staged by Mr. S. Coe, grower to Earl SPENCER, K.G., Northampton; by Mr. T. JONES, of Ruabon, and Mr. W. MARBLE, of Penkridge. The competitive classes were accommodated on four tables, each 90 feet long by 6 feet wide, placed down the body of the hall with a division in the middle to facilitate access to different parts of the building. This was much appreciated by exhibitors and public alike. Tables decorated with Sweet Peas were arranged near one end of the hall, and the non-competitive groups were placed against the side walls, each exhibitor being allotted 20 feet run of staging. There were upwards of 50 exhibitors and about 400 varieties were staged in the 41 classes, 19 of which were special classes, the prizes being provided by 15 seedsmen.

OPEN TO MEMBERS OF THE SOCIETY.

The premier class was for 24 varieties, distinct, for which five prizes, including the Silver Medal of the National Sweet Pea Society, were offered. There were some very fine blooms in the 1st prize collection, which came from Earl SPENCER, K.G., Northampton (gr. Mr. S. Coe). The flowers were large, of great substance, borne on strong stems and well arranged. The varieties were Lord Althorp, Countess Spencer, Gladys Cole, G. C. Ward, Lady Althorp, Earl Spencer, John Ingman, Prince of Asturias, Mrs. Hardcastle Sykes, Sea Foam, Elsie Herbert, Miss Lavinia Spencer, Lady Sarah Spencer, Frank Dolby, Silas Cole, Althorp Cream, Helen Lewis, Miss Delia Spencer, Althorp White, and five unnamed seedlings. 2nd, Mr. C. W. BREADMORE, Winchester, with a meritorious display. 3rd, Messrs. G. STARK & SON, Great Ryburgh.

In a class for 12 varieties, distinct, Messrs. G. Stark & Son were placed 1st with exquisite flowers of Enchantress, Improved Dorothy Eckford, Beauty of Fife, Paradise Ivory, Frank Dolby, Menie Christie, Special II, Lewis, Mrs. C. W. Breadmore, George Herbert, Mrs. H. Bell, A. J. Cooke, and Jeannie Gordon. 2nd, Mr. W. S. HESLINGTON, Littlethorpe, Ripon.

(TRADE EXCLUDED.)

In a class for 18 varieties there were five exhibits, and the one that gained the highest award came from Mr. C. BARRATT, Marcroft Road, Tettenhall, who had a splendid lot of flowers beautifully arranged. The following varieties were of outstanding merit: A. J. Cook, Lord Nelson, Mrs. Hardcastle Sykes, Helen Pierce, Hannah Dale, Romolo Piazza, Sarah Eckford, King Edward VII., Dorothy Eckford, George Herbert, Jeannie Gordon, Prince Olaf, and Nora Unwin. 2nd, W. LEONARD S. LOAT, Esq., Cunnor Place, Oxford (gr. Mr. Jas. Webb).

The last-named exhibitor took the lead in a class provided for 12 varieties, distinct, having good examples of Sybil Eckford, Jeannie Gordon, Crissie Unwin, Helen Lewis, Prince of Asturias, Countess Spencer, Frank Dolby, Mrs. Collier, Duke of Westminster, Agnes Eckford, and John Ingman. 2nd, Mr. W. S. HESLINGTON.

Nine varieties, distinct.—In this class there were 11 good exhibits, and of these Mr. W. KENDRICK, Tettenhall, was placed 1st with good flowers of Helen Pierce, Countess Spencer, Sybil Eckford, Eta Dyke, John Ingman, Frank Dolby, Mrs. Hardcastle Sykes, A. J. Cook, and Elsie Herbert. 2nd, Mr. W. E. Lowe, Shrewsbury.

In a class for 12 varieties, to be grown within five miles of the exhibition hall, there were seven entries. E. J. FORSYTH, Esq., The Bell, Tettenhall (gr. Mr. H. Bott), won the 1st prize with exquisite flowers of Mrs. Hardcastle Sykes, Lord Nelson, John Ingman, Queen Alexandra, Prince Olaf, Helen Lewis, and Henry Eckford. 2nd, Mr. T. DAVIES, Grange Road, Tettenhall.

Six entries were made in a class provided for six varieties, distinct, having waved standards. The 1st prize was awarded to Mr. W. MARBLE, Summer House, Penkridge, who had superb flowers borne on strong stems. The varieties were Mrs. Hardcastle Sykes, White Spencer, John Ingman, Mrs. C. Foster, Audrey Chier, and Paradise.

SINGLE BUNCH CLASSES.

Twelve classes were provided for these, and in the majority of them competition was very keen and the flowers of a very high standard of excellence. The most successful exhibitors were Mr. THOMAS JONES, of Ruabon, and Mr. W. MARBLE, of Penkridge. Mr. JONES staged the winning flowers in the following classes: Scarlet or crimson, King Edward VII.; orange, Henry Eckford; yellow or buff, Clara Crute; maroon, Black Knight; and striped, flaked, or decorated, Helen Pierce. Mr. W. MARBLE was awarded 1st prizes in the under-mentioned classes: White, Nora Unwin; blush or pink, Paradise; and fancy, Sutton's Queen. Other 1st prize winners in this section were W. L. S. LOAT, Esq. (gr. Mr. Jas. Webb), and Mrs. EVANS, Newbridge Crescent, Wolverhampton (gr. Mr. R. Maybury).

DECORATIVE CLASSES (TRADE EXCLUDED).

Six tables, each measuring 8 feet by 4 feet, decorated with Sweet Peas, were before the lady judges, who awarded the 1st prize to Mr. W. MARBLE for a pleasing design of pink flowers relieved with sprays of white and fronds of Adiantum cuneatum. 2nd, Mrs. F. C. WOODWARD, Wolverhampton.

The last-named exhibitor brought the best specimen of Sweet Peas, and Mr. W. JONES, Tettenhall, had the best arranged bowl of similar flowers.

SPECIAL PRIZES.

Messrs. Baker offered prizes in two classes, one for 12 varieties and the other for six varieties. There were nine exhibits in the first class, and seven exhibits in the second class. Mr. W. MARBLE showed the best collection of 12 varieties, having handsome flowers borne on strong stems. The varieties were St. George, Janet Scott, Queen Alexandra, Mrs. Collier, Lord Nelson, Jeannie Gordon, Phenomenal, Countess Spencer, Dora Breadmore, Helen Lewis, Nora Unwin, and John Ingman. 2nd, Mr. T. JONES.

In the class for six varieties Mr. T. DAVIES, Grange Road, Tettenhall, was placed 1st with excellent flowers of Countess Spencer, Nora Unwin, Dorothy Eckford, &c.

Prizes offered by Messrs. Alee, Burpee & Co. were for six varieties of the Countess Spencer type, and some very fine flowers were exhibited. The 1st award went to Mr. W. MARBLE, whose flowers were Constance Oliver, White Spencer, Countess Spencer, Primrose Spencer, John Ingman, and Elsie Herbert. 2nd, Mr. T. JONES.

Mr. Henry Eckford's prizes were for 12 varieties shown in 12 vases. Three prizes were offered in each class, and some very fine flowers were shown.

Miss H. HEMUS offered prizes in two classes, for the best vase of either Evelyn Hemus, Paradise Carmine, Paradise Ivory, White Paradise, or Paradise Regained. The 1st prize was well won by Mr. W. MARBLE, who had grand flowers of Evelyn Hemus. 2nd, Mr. W. S. HESLINGTON.

Mr. Robert Sydenham offered prizes for nine varieties. Mr. T. JONES was placed 1st. He had superb flowers of Mrs. Hardcastle Sykes, Mrs. Collier, Frank Dolby, Countess Spencer, Helen Lewis, and King Edward VII. Mr. R. Sydenham also offered prizes for the best vases of Miss Millie Maslin and Herbert Smith. The 1st prize in each class went to Mr. W. MARBLE and Mr. T. JONES respectively. The last-named exhibitor won the 1st prize in a class for six varieties provided by Mr. W. J. Unwin.

Messrs. Webb's prizes were for nine varieties, and the 1st prize was won by ALFRED ASHWORTH, Esq., Horsley Hall, Gresford (gr. Mr. H. Shaw).

In a class for six varieties in which the prizes were provided by Mr. Horace J. Wright, there were four entries. Mr. W. MARBLE won the 1st prize with splendid flowers of St. George, Primrose Spencer, Queen Alexandra, Phenomenal, Helen Lewis, and Nora Unwin.

Special prizes were also offered by several other seedsmen.

NON-COMPETITIVE EXHIBITS.

Messrs. DOBBIE & Co., Rothsay, had an assortment of new and old varieties of Sweet Peas arranged in vases and tall bamboo stands. The most noteworthy were St. George, E. J. Castle, Princess Victoria, David Cuthbertson, James Grieve, Nora Unwin, Evelyn Hemus, and Paradise.

Prince Olaf, Helen Lewis, John Ingman, and Countess Spencer. (Silver Medal.)

Messrs. W. H. SIMPSON & SONS, Birmingham, had a prettily arranged group, in which the varieties 'Elsie Herbert, King Edward VII., Frank Dobby, Olive Belmont, Sutton's Queen, Mrs. Charles Foster, Mrs. Hardestade Sykes, Queen Alexandra, Mrs. Henry Bell, A. J. Cook, Henry Eckford, and St. George were shown. (Gold Medal.)

Mr. ROBERT SYDENHAM, Birmingham, had rustic stands decorated with Sweet Peas of good quality. (Silver Medal.)

From Messrs. JONES & SONS, Shrewsbury, came a large number of well-grown varieties. (Gold Medal.)

Messrs. G. STARK & SON, Great Ryburgh, sent a collection of the more notable varieties. (Silver Medal.)

Mr. JOHN E. KNIGHT had a large collection displayed in vases and bamboo stands, relieved with Asparagus and Gypsophila. (Silver Medal.)

Messrs. BAKER'S, Wolverhampton, in an artistically-arranged group showed the best of the old varieties and quite a number of recently-introduced varieties. (Gold Medal.)

Mr. C. W. BREADMORE, Winchester, sent a group of well-grown varieties. (Gold Medal.)

Messrs. T. B. DOBBS & CO, Wolverhampton, had vases, baskets, and bouquets of Sweet Peas. (Silver Medal.)

BISHOPS STORTFORD HORTICULTURAL.

AUGUST 3.—The annual show of the above Society was held on August Bank Holiday, and a large number of visitors attended. The displays of fruits and vegetables were excellent, but Roses appeared to have suffered from the great heat. The best blooms came from the gardens of T. E. CROFT, Esq., Stanstead Abbots, Ware, Herts., and easily secured the 1st prize. Some splendid Phloxes were seen. The 1st prize for a collection of 12 distinct kinds was awarded to Mrs. W. GEE, Elmhurst (gr. Mr. W. Wilkinson). The collection contained a new variety named W. Wilkinson, to which a First-Class Certificate was awarded; the colour is rose with a white centre. Collections of herbaceous flowers are generally a feature at this show, and those staged this year were no exception to this rule. Messrs. PAUL & SON, Cheshunt, again secured the 1st prize with a grand display in the class for 24 distinct kinds. Their Phloxes were very fine, also Scabiosa caucasica alba, Chrysanthemum King Edward, Aconitum pyrenaicum, and Platycodon grandiflora.

The best group of plants arranged for effect was staged by Mr. Vert (gr. to the Rt. Hon. Lord HOWARD DE WALDEN, Audley End, Saffron Walden). He utilised 'Odontoglossum' (Crotone) grandly coloured, Liliun auratum, Dracena Lindenii, and other foliage plants, tastefully arranged. Begonias in pots were very good, some fine varieties being staged, evoking strong competition. The premier award was made in favour of JOHN BARKER, Esq., M.P. (gr. Mr. G. Beech). The Grange, Bishops Stortford. Miss F. SPENCER, Stanstead, won the 1st prize in the class for table decorations. She utilised Ruby Castle Carnation, and grasses in low glasses. Miss VERT, Audley End, was 2nd with a beautifully-arranged table of Odontoglossum crispum lightly disposed.

Fruit was well shown in most classes; the best collection was shown by Col. ARCHER HORTON (gr. Mr. Harrison, Hallingbury Place, Bishops Stortford). The exhibit contained grand bunches of Muscat of Alexandria and Muscat Hamburg Grapes, also good Peaches, Nectarines, and a Melon.

Vegetables occupied a considerable space, and were generally of good quality; the premier award for a collection of 12 varieties was secured by J. B. BALFOUR, Esq. (gr. Mr. Jeffries), Moor Hall, Harlow, Essex.

Groups of plants and cut flowers contributed by well-known growers not for competition form a leading feature of the show. In these exhibits there were excellent specimens of most of the hardy plants now in flower, as well as of species that need cultivation indoors.

MARKETS.

COVENT GARDEN, August 5.

(We cannot accept any responsibility for the postponed issue of the market report which will appear every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are selected, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.)

Cut Flowers, &c.: Average Wholesale Prices.

Table listing prices for cut flowers such as Alstromerias, Aspers, Calla aethiopica, Carnations, etc.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing prices for cut foliage such as Adiantum, Asparagus plumosus, Ferns, etc.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing prices for plants in pots such as Ampelopsis, Aralia, Begonia, etc.

Table listing prices for plants in pots such as Rhodanthe, Roses, Scabiosa, etc.

Fruit: Average Wholesale Prices.

Table listing prices for fruit such as Apples (English), Apricots (French), Currants (English), etc.

Vegetables: Average Wholesale Prices.

Table listing prices for vegetables such as Artichokes, Beans, Broccoli, etc.

REMARKS.—Home-grown Tomatoes are arriving in much larger quantities owing to the extreme weather of the past week. Prices for these have fallen considerably. Kentish Cherries are realising good prices, especially Bigarone Napoleon. English Plums are being sold cheaply, there are large consignments of French varieties. During the past week, some very fine Washington Navel Oranges arrived from Natal and realised high prices. (F. H. R., Covent Garden Market, Wed., August 5, 1908.)

Table listing prices for potatoes and lincolns such as Kent's Snowdrops, Lincolns, etc.

COVENT GARDEN FLOWER MARKET. Holders disorganise all trades, but none more than the flower business. Cheap hardy flowers are selling fairly well, but the London florists generally are experiencing a dull

season, many of their customers being on holiday. Many of the growers and salesmen are themselves also taking holiday, and the market, in consequence, presents a deserted appearance. There will not be any considerable improvement in the second week in September. Orders received from the province constitute the chief trade.

CUT FLOWERS.
Some growers of Sweet Peas inform me that they have done fairly well this season, but all say prices are much lower than in previous years. Those who have kept to the most distinct shades of red, mauve, pink, and palest whites, have done best; my attention recently was directed to Nora Unwin variety, but I cannot recommend it for market sale in the present season. The "Eckford," was latter variety having much more substance in the petals. Frank Dobby may prove a useful mauve variety, but Lady Grisel Hamilton will remain a favourite, and it will require keeping exceptionally good to displace Miss Willmott from public favour, for, in addition to the pleasing shade of colour, I know of no other Sweet Pea which keeps better after it is cut. There has been a great drop in the prices for Chinese Asters, for they are over plentiful, many being received from abroad. *Cypripedium pendulum* is now well flowered. *C. elegans* is also very good. *Saponaria vaccaria* of the rosy-pink variety is also extensively grown. Border Carnations are abundant, but they are not so much appreciated as the American varieties, their value is about that of a few years ago. Prices for the best American varieties are very low. *Roses* vary considerably; the best blooms have sold fairly well, but supplies smaller blooms have been excessive. Gladioli of various sorts are good and cheap. *Galatardia*, *Scabiosa*, the large single white *Chrysanthemum*, and *Statice* of various sorts are at their best. Lavender is a prominent feature, and street hawkers buy this in preference to other flowers. *Gardenia*, *Eucharis*, and *Stephanotis* are not abundant.

POT PLANTS.
It is now very uncertain what may and may not be procured. *Rambler Roses* in various sizes have been very good, but few Hybrid Perpetual *Roses* are seen. *Fuchsias* are plentiful in all sizes and colours, but there is no demand for them. Many *Coleas* are cleared out at prices which can barely pay for the pots and soil. *Lilium longiflorum* is more plentiful than ever. *Hyacinths* I noted some extra fine plants of *L. rubrum*; good Ivy-leaved varieties are not over plentiful. *Foliage plants* vary but little, except that *Growers* who have their stands partially filled with bedding plants have them now occupied with *Fuchsias*. A. H., Covent Garden, Wednesday, August 5, 1908.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD OF THE weather throughout the British Islands, for the week ending Aug. 1, is furnished* by the Meteorological Office:—

GENERAL OBSERVATIONS.
The weather.—Over the United Kingdom generally the weather was fine, warm and dry. Frequent slight falls of rain were, however, experienced on our extreme western and northern coasts, and in some occasions the showery weather extended over considerable portions of Ireland, Scotland and Wales, as well as some parts of northern and central England.

The temperature was slightly below the average in Scotland, the north-west of England and the north of Ireland; elsewhere it was above the normal. The highest reading was 79° at many places in eastern, central and southern England the maximum readings on the 26th were above 80°, the highest value reported being 83° at Geddleston and Round. The lowest readings were observed mainly on July 29 and August 1. In some parts of Scotland and southern England the sheltered thermometer on one or other of those occasions fell below 40°, and in Scotland E. (Balmorah) it fell to 35°. The surface of the ground a slight frost occurred on the night of the 28th in several parts of Scotland and central Wales, the exposed tundra of the Cairn Balmorah, to 30° at Llangamarch Wells and to 31° at Crathes.

The mean temperature of the sea.—Around Ireland and on some parts of our north-east coasts the sea water was clear, bright, and calm, but in most instances the surface of the coast of Great Britain generally it was somewhat warmer.

The rainfall was very deficient over the country generally, many stations in eastern, central and southern England being without any rain during the week, which commenced shortly after the middle of July. In the north and west of Scotland, however, about half the average quantity was recorded.

The bright sunshine was generally in excess of the average, but in most of the northern districts the excess was small, and in Scotland N. there was a slight deficiency. Over Scotland the total amount of bright sunshine was very large, more than 60 per cent. of the possible amount being recorded in the Midland Counties and in England S.W., and more than 70 per cent. in England E. and S.

THE WEATHER IN WEST BERKTS.

Week ending August 5.

Another warm, dry and sunny week.—The days again proved very warm, the highest reading of the thermometer screen on each day but one exceeding 70°, and on two of them rising as high as 82°. On the other hand the nights were a little colder than in the week ending July 29, and the night the thermometer exposed on the surface of the soil fell to within 4° of the freezing-point. Both at 1 and 2 feet deep the ground is at the present time about 2° warmer than it was a week ago. No rain has fallen in more than 14 1/2 hours, and no rainwater at all has passed through the barometer-percolation gauge for several days. The record of the highest sun being 81° on the 2nd during the week, the mean daily duration amounting to as much as 14 1/2 hours, which is five hours a day in excess of a seasonable quantity—making this the brightest week as yet of the present

summer. Calms and light airs again prevailed. The mean amount of moisture in the air at 4 p.m. was 8 per cent. less than a seasonable quantity for that hour.

JULY.

Seasonable in temperature and rather dry.—Taken as a whole this proved a July of about seasonable warmth. During the first week and the last ten days the weather remained warm, but during the intervening night there did not occur a single unseasonably warm day. On the warmest day of the month the temperature in the thermometer screen rose to 88° and on the coldest night it fell to 48°. The thermometer fell only to 40°. The latter is, with two exceptions, the highest extreme minimum reading I have recorded in July during the 22 years over which my records at Berkhamsted extend. On the 14th the thermometer fell to 48°. The aggregate depth of 24 inches, which is slightly in defect of the mean for the month. No rain at all fell during the last 12 days. The sun shone on an average for 12 hours a day, or for as long as thirty as possible its usual duration in July. The winds were as a rule light, and on no hour did the mean velocity exceed 15 miles—direction W.S.W. The average amount of moisture in the air at 3 o'clock in the afternoon exceeded a seasonable quantity for that hour by 3 per cent. E. M., Berkhamsted, August 5, 1908.

GARDENING APPOINTMENTS.

- Mr. R. DOL, for 3 Years Gardener to the Earl of Suffolk, Charlton Park, Malmsbury, as Gardener to MARTIN J. SUTTON, Esq., Holme Park, Sonning, Berkshire.
- Mr. F. DEANEY, Gardener to A. H. FULCHER, Esq., Redbank Park, Andover, and 6 years previously Gardener at Scotsburgh House, Rickmansworth, Herts, as Gardener to G. E. GRIBBLE, Esq., Biddesden House, Andover, Hampshire.
- Mr. H. WELLS, for the last 12 months Inside Foreman in The Gardens, Perry Hall, Birmingham, as Gardener to H. H. JOY, Esq., Olton Hall, near Birmingham.
- Mr. A. HOUR, for the last 13 years Gardener to the late Mrs. W. H. ELIAS, Astoney Grange, Leicester, as Gardener to FRANCIS N. ELLIS, Esq., Debdale Hall, Mansfield, Notts. (Thanks for 2s. 6d. sent for K.G.O.F. box).
- Mr. E. LYNE, the Foreman at Hopdene Gardens, Holmby, St. Albans, as Gardener to A. F. MARLOW, Esq., Preston Deanery Hall, Northamptonshire.

ASTER: J. J. T. There is no fungus disease present, and it is impossible for us to determine the cause of failure.

BEECH LEAVES: E. W. K. The spots on the leaves are caused by a mite called Phytomyces. They were at one time considered to be fungi until shown to be a minute kind of gall.

BLACK HAMBURG GRAPES: ANXIOUS. From the facts particulars you have given regarding the Black Hamburg vines it is difficult to give positive reasons for their differing from each other with respect to their fruiting and manner of growth. If the vines were of the same age and of a similar degree of health when planted, and the borders throughout are of like formation and dimensions, it is singular that the vines should exhibit such diversity of character, provided they are all of the same kind of Hamburg, and are all growing in their own roots. It is well known that, if a vine is inched or otherwise worked upon another vine, the latter is considerably altered its character—in some instances improving it. Your vines may represent two distinct varieties, possibly the true Black Hamburg, which is commonly grown, and Mill Hill Hamburg. The latter, under some conditions of culture, makes very gross growth, its leaves being large and its wood difficult to thoroughly mature as compared with the true Black Hamburg. Old vines of Mill Hill Hamburg yield perfectly black berries of ordinary size, but the variety is less satisfactory whilst the vines are young.

CARNATIONS: J. S. and J. J. Z. The roots appear to have been watered off, or to have decayed at the point where the plants were layered. From the specimens themselves, it is impossible to determine the exact cause. The soil may contain wireworms.—W. J. R. Your flowers appear to be varieties of what are known as "Marguerite" Carnations, a type which is very easily raised from seeds, and one which has great garden value.

CELERY LEAF SPOT: A. H. The spots on the leaves are caused by a fungus known as Septoria. The diseased leaves should be burnt, and the plants syringed with the Bordeaux mixture.

CREOSOTE BOARDS: J. B., Latham. The introduction of freshly-creosoted boards into ainery or Peach-house may have detrimental effects upon the crops. If creosoted boards are to be used, they should be exposed in the open air for some weeks before introduction into the houses.

CUCUMBER LEAF SPOT: L. H. The spots do not appear to be caused by the spot mould. As *F. fungus* is present, probably the failure is from the presence of excessive moisture.

DIANTHUS: Correspondent. No. 4 is a form of *Dianthus plumarius*, the garden 'pink'; it is not so deeply fringed as the wild form. (5) This may be *Dianthus superbus*, which does not flower before August. The flowers are white or rose coloured, but they were too much faded to be recognised with certainty.

FOXGLOVE: A. B. The common Foxglove (*Digitalis purpurea*) is generally considered a biennial plant, although it may occasionally live for a longer period. In these circumstances, the judges can hardly be blamed for disqualifying an exhibit of Foxgloves in a class which excluded any but perennial plants.

FRENCH GARDEN: J. D. We cannot undertake the responsibility of advising you in regard to the offers you have received. So much depends upon the probity and conscientiousness of the person with whom you would enter into a kind of limited partnership. As neither business is yet established, there should be some guarantee for the safe investment of the money.

GARDENER'S DUTY: H. G. We do not know of a rule by which a foreman or journeyman cannot be considered on duty after 6 p.m. The rule in most gardens is that some of the journeymen have to be on duty during the whole of the evening. The day's work is supposed to terminate at the usual time for the workmen in that particular garden to leave their duties, and any duty that has to be performed after that time should be considered extra to the day's work, and be paid for.

GAS WATER: W. P. We do not think that gas water is of sufficient garden value to recommend it for watering crops in a diluted condition.

GREENHOUSE IN WINTER: H. G. Z. It is impossible to give you a precise answer owing to the fact that you have not stated the dimensions of the greenhouse. If the subjects in the house are ordinary greenhouse species, the house are ordinary greenhouse species, and you provide the structure with means of maintaining an atmospheric temperature of 40° during severe frost in winter, this will suffice, but what amount of water apparatus and boiler power will be necessary must depend upon the number of cubic feet of space to be heated.

HELIXE SOLEIROLII: E. C. C. D. This mallow-growing plant is the sole member of the genus, and is a native of Corsica and Sardinia. It belongs to the N. O. Urticaceae, and, in common with most plants of that order, the flowers are small and insignificant. It much resembles in general appearance our native *Sibthorpia europaea*, but the leaves are unequally lobed. The plant has not been long grown in gardens in this country, but its culture is spreading, as it forms a valuable subject for carpeting the surface of a pot or bare places on the floor of a plant house.

NAMES OF PLANTS: J. M. Please send the *Scelmus* when the plants are again in flower. It is next impossible to name them in their present condition. The *Nierembergia* is infested with a mildew, but it has nothing to do with the fungus that causes the spot disease of Cucumbers.—H. G. 1 and 2, *Crepis* species, probably *C. virens* and *C. biennis*; 3, *Ectemecarpus scaber*; 4, *Equisetum arvense*; 5, *Veronica* sp.; 6, *Lotus corniculatus*.—W. J. B. *Elymus vulgare*.—E. H. B. 1 and 3, *Lonicera japonica* var. *flomosa*; 2, *L. japonica* *Hollandia*; 4, *Rubus odoratus*; 5, *Asclepias tuberosa*.—F. H. 1, *Inula ensifolia*; 2, *Epiobolium angustifolium* album; 3, *Clematis vitalba*; 4, *Veronica* sp.; 5, *Sedum punctatum*; 6, *Helianthus pumilus*.—J. P. 1, *Liatris spicata*; 2, *Francoa appendiculata*; 3, *Azraea alba*; 4, *Lathyrus*, not in flower; 5, *Nepeta Glechoma*; 6, *Campanula pumila*.

alba; 7. *C. garganica*.—*A. B. H.* You should have numbered each specimen; a numbered list is quite insufficient: we have, however, done our best: 1, *Polygonum compactum*; 2, *Linaria* sp., no flowers remained; 3, *Gentiana Regellii* alba; 4, *Campanula nitida*; 5, *C. pusilla*; 6 and 7, specimens withered; 7, *Dianthus cruentus* var.; 8, *Zygadenus elegans*.—*C. O. V.* 1, *Senecio Jacobea*; 2, not recognised; 3, *Betula nigra*; 4, *Campanula rotundifolia*; 5, *Prunella vulgaris*; 6, *Galium mollugo*.—*A. C. Bartholomew.* 1, *Pentstemon* sp.; 2, *Gentiana cruciata*; 3, probably *Brachycome Iberidifolia*. *E. C. C. D.* *Veronica Lyallii*.—*J. T. J.* *Michauxia campanuloides*, a biennial species.—*A. J.* *Castanea Sativa* (perhaps var. *prolifera*). The Spanish Chestnut varies greatly in minor details of leaf.—*Benjamin.* *Indigofera Dossun*.—*C. S.* 1, *Adiantum fulvum*; 2, *Jacobinia (Justicia) carnea*.—*E. H.* *Hyoscyamus niger*; *Henbane*.

NECTARINE EARLY RIVERS: W. C. The skin is shrivelled owing to exposure to bright sunshine whilst condensed moisture was on the fruits. You must ventilate the house early in the morning, that the fruits may become dry before the sun gains much power. A fruit to every 9 inches or one foot of space is considered a satisfactory crop, but many cultivators crop their trees much more freely and endeavour to keep the trees in a healthy condition by supplying them with a greater quantity of nutrition than would be given were the crop less plentiful.

PEACH LEAVES: M. W. The leaves are affected with the Shot-hole fungus (*Cercospora circaeissae*). Next season spray the trees with the ammoniacal solution of copper carbonate just when the leaves are expanding, and repeat the spraying at intervals. This is prepared by taking of copper carbonate 1 ounce, carbonate of ammonia 4 ounces, and water 16 gallons. Mix the carbonate of copper and the carbonate of ammonia, and dissolve it in about a quart of hot water. When thoroughly dissolved add 16 gallons of cold water.

CROSS BETWEEN BLACK CURRANT AND GOOSEBERRY: H. W. A. A hybrid between the Black Currant and Gooseberry was described in the *Gardener's Chronicle*, September 3, 1892. We reproduce the illustration that accompanied that description at fig. 45, and it will be seen that your plant presents some interesting features in which it differs from the former hybrid. The fruits are somewhat similar, except that in the 1892 hybrid they were somewhat hairy, though this character was accidentally omitted in the figure, but whereas in that specimen the general resemblance was rather towards the Currant, your hybrid is decidedly inclined to the habit of the Gooseberry. This is shown by the smaller leaves, and especially by the presence of numerous prickles or thorns, which were absent in the former examples. The green shoot has an unmistakable odour of the Black Currant, and the flavour of the latter is also perceptible in the fruits, which are very little larger than good-sized Currants.

PEARS: E. W. The Pears are affected with the ordinary *P. scab*, *Fusicladium pyrinum*, a disease difficult to cure, though this character held (*Gard. Chron.*, Nov., 1885, figs. 155, 156). Gather and burn all diseased fruits. In the early spring spray with sulphate of iron. When fruit is set, apply Bordeaux mixture.

PEAS: J. W. The specimens afford no clue to the cause of failure. There must be some local cause, due to faulty treatment or otherwise.

PLANE TREE: W. P. You might spray the trees with an insecticide, but it is very difficult to treat large trees successfully.

RED CURRANTS: Ethel M. E. There is nothing at fault in the cultivation, for we do not see how this would affect the setting of the crop. Climatic conditions were evidently favourable to the proper fertilisation of the flowers, therefore most of the fruits had their proper number of developed seeds. You do not state what variety you cultivate, but perhaps it would be possible to choose a variety which usually develops few seeds, as is done in the case of Tomatoes and many other fruits.

SHRUBS FOR A NORTH-WEST WALL: B. Z. Of those you name, *Schizophragma hydrange-*

oides and *Spiraea Lindleyana* are quite hardy and capable of flowering well in the Midland counties. *Bupleurum fruticosum* is rather tender and shy in blooming; *Choisya ternata* grows freely, but only flowers satisfactorily after hot summers. It is, however, worth growing, for the sake of its handsome, glossy, green foliage. *Eriobotrya japonica* is not hardy. The undermentioned shrubs are hardy and likely to answer your purpose:—*Hamelis arborea*, a Japanese Witch Hazel, bearing small flowers composed of narrow, wavy, golden-yellow petals and claret-coloured calyxes in February; *H. mollis* is another species of much merit. *Prunus triloba*, one of the loveliest of spring flowering shrubs, is perfectly hardy. Its semi-double rose-pink flowers wreath the long, slender shoots on which they are borne. *Indigofera Gerardiana* produces a wealth of rose-purple pea-shaped flowers in July quite distinct from everything else. *Staphylea Coulombieri* bears flowers similar to those of the better-known species

sporum solani). Cut away any diseased foliage and fruit and burn them. Afterwards spray the plants occasionally with potassium sulphide. This is made by employing 2½ gallons of water and one ounce of potassium sulphide. Dissolve the potassium sulphide, or liver of sulphur, as it is often called, in a quart of hot water. Then make it up to 2½ gallons with cold water. It should not be allowed to come into contact with paint, or it will turn it black. *Correspondent.* Tomato fruits frequently crack owing to improper regulation of the cultural conditions; the property, therefore, in such cases is not likely to be hereditary. The skins may, however, crack owing to the presence of fungus or from some other cause. It is best to take no risk, and we should therefore recommend you to save your seeds from fruits of the most perfect form, having solid flesh, good flavour, few seeds, and which have not cracked their skins. **TULIP ROT: S. W.** The bulbs are originally rotted by a mould named *Botrytis*, which in

FIG. 45.—HYBRID BETWEEN BLACK CURRANT AND GOOSEBERRY.

S. colchica, from which it differs by reason of its larger flowers borne in longer racemes. *Xanthoxeris sorbifolia* is an uncommon shrub from China, with small white flowers blotched with purple at the base. They are borne in erect racemes. *Halesia tetrapetala* (Snowdrop tree) bears great quantities of snow-white drooping flowers in April and May. *Exochorda Albertii* is by no means well known. It is very handsome and quite hardy; the flowers are single and white. *Azara microphylla* is remarkable for its long, flat, arching shoots and tiny, deep-green leaves and great profusion of small, sweet-scented, greenish-coloured flowers. *Akebia quinata* is of free growth and produces pale, purple flowers in March and April. *Escallonia Philippiana*, a small white-flowered species from Valdivia, and *E. Langleyensis*, a hybrid between the last-named species and *E. sanguinea*, should be included. Both are hardy, and blooming freely. *Elaeagnus puegens aurea* is one of the showiest and hardiest of evergreen shrubs. *Buddleia variabilis Veitchiana* is a grand plant, with long spikes of bright mauve flowers.

SILVER LEAF: F. W. Appears to be the silver leaf disease, but we are unable to recommend a remedy.

TOMATO: R. R. Lancaster. Your plants are affected with the Tomato Black Rot (*Macro-*

your specimens is leached by the common blue mould on the lead tissues. We would recommend the burning of all the diseased bulbs, and sterilising the soil. Bulbs should not be planted on the same patch for a year or two afterwards.

VINES: Enquirer. To vaporise vines with the X.L.—All vapourising compound after the Grapes are colouring would probably leave a distasteful flavour on the fruit, though it would not otherwise cause injury to the vines. Vines, while making growth, should not have their leaves syringed during the time they are exposed to powerful sunshine. Up to the time the blossoms expand, syringing of the leaves should be done on fine days early in the morning, before the sun gains much power, and again early in the afternoon when the house is closed for the day, but after the flower-buds open the amount of atmospheric moisture necessary should be created by damping the ground surface and paths inside the house.

leaves known as Septoria Lycopersici. It was discovered by Spegazzini as long ago as 1884 in the Argentine, the home of the Tomato. Soon after the introduction of this fruit into Australia, the disease appeared there also, and it followed the Tomato wherever it was introduced subsequently. Thus it is known in Italy, France, Germany, Scandinavia, and has arrived now in England. Whether it is going to stay here and be allowed to spread will depend upon the importance the reader attaches to this report.

From the following experiments it can be gathered how virulent the disease is in its attacks, and how quickly it is capable of effecting complete destruction.

Diseased parts of a leaf were placed into a small bottle containing water. The germination of the spores of the fungus present took place within six hours. This water, containing spores in abundance, was sprayed on a healthy Tomato plant on August 11. On August 16 the first spots were noticed, and by August 20 the whole plant was attacked. The disease did not confine itself to the leaves in my experiment, the stem, the shoots, the calyx, and the young fruits were also attacked, showing spots of the same appearance as on the leaves.

magnification with a pocket lens the observer can recognise in these decayed patches a number of very minute, inky-black, raised pustules (see fig. 40b and c). These pustules are the fruiting portions of the fungus, being small black conceptacles filled with numerous long, needle-shaped spores, which are divided in from five to twelve divisions (see fig. 40b). When the spores of the fungus are ripe, they are shed and contaminate the whole house, including even the wood, glass, wire and stakes.

One of the main points in curing a disease is the application of common-sense to the particular circumstances, and now that the story of the fungus is told, the measures I suggest for use against it may be improved upon by cultivators with experience gained in combating similar diseases.

If a whole house is infected, pull up all plants and burn them immediately, outside the house, using plenty of straw, &c. Take care not to carry the diseased plants about too much, or the spores will be disseminated. Next remove systematically about 6 inches of the top soil from the borders, and mix it well with quicklime—to every five barrowful of soil add one barrowful of lime. This soil may safely be put back again after the lime

FIG. 46.—SEPTORIA SPOT ON TOMATO LEAF.

SEPTORIA SPOT.

A NEW FUNGUS DISEASE OF TOMATOS.

WITHOUT wishing to unnecessarily alarm the growers of this important fruit, I must call their attention to the appearance of a new pest which is likely to become the most serious and destructive among Tomatos unless preventive measures are adopted.

In July last year, I was asked to investigate a leaf-disease of Tomatos that in Gloucestershire has destroyed a crop of out-door Tomatos within a very short time. The disease was investigated and subsequently the results were published in Vol. xv., No. 2, May, 1908, of the Journal of the Board of Agriculture. This year the disease has made its reappearance, attacking seedling plants and fruiting plants indoors. The leaves of the affected plants become discoloured in parts, till they reach, finally, a greenish-black tint, when they hang limp from the plant. In a short time the plants are killed.

There is a fungus present on the diseas-

ed leaves. Within five days from spraying, ripe spores were produced on the infected plant, and after twelve days the plant died. The plants used for experiments were strong, healthy specimens about 3 to 4 feet in height; others not inoculated for comparison bore a number of good fruits.

I append a short description of the fungus, and suggest "Septoria spot" as a popular name to distinguish this disease of the Tomato from any other.

When the disease is first noticed, it is on account of a number of scattered, concentric spots of a bluish-green colour appearing on the surface of the leaves. Soon these spots enlarge (see fig. 40a) and new ones appear, thus they become confluent, and finally larger patches of dark tissues are noticed, which eventually are distributed over the whole leaf, which becomes totally black. These spots are due to the growth of a fungus within the tissues of the leaf. When growing, the fungus absorbs the contents of the plant cells and these discolour and collapse, thus the visible spots of blackened tissues. Under

has been allowed to slaken. Any wires and props used in the house should be drawn through fire to kill the spores adhering to them. The paths, woodwork and glass inside the house should be attended to also. The paths should be drenched and the woodwork and glass washed with a 4 per cent. solution of sulphate of copper.

If a water-tank is in the house, mix the water (calculating its quantity) with the necessary quantity of sulphate of copper and use it for washing. This will kill the fungus spores in the water. Afterwards empty the tanks and refill with clean water.

Plants once attacked can be saved only if sprayed as soon as the first signs of the disease are noticed. For that reason one must be on the look-out for the small spots which first appear. They can be noticed on quite healthy, dark green leaves. If such signs are seen, the plants should be sprayed immediately with a 3 per cent. solution of the Bordeaux mixture early in the evening, every alternate day for two weeks. The finer the spray falls upon the plant the better, and the less

is wasted. The spraying of Tomato plants with a 4 per cent. solution of the Bordeaux mixture has resulted in injury to the leaves, and should not be practised.

When planting Tomato plants scatter some pulverised lime round the stem. It having been found that the disease is spread by means of Tomato seeds, seeds from infected areas should not be used unless they are immersed for one hour in a 5 per cent. solution of sulphate of copper. *H. T. Güssow, London Botanical Laboratory, 44, Central Hill, Norwood, S.E.*

NEW OR NOTEWORTHY PLANTS.

ASPARAGUS FILICINUS.

ALTHOUGH this plant was described by D. Don in his *Prodromus Floræ Nepalensis*, p. 49, as long ago as 1825, it does not appear to have been cultivated in Europe until 1898, when a form of it was introduced into the Botanic Gardens at Florence. It has also been grown by Sir Trevor Lawrence, and exhibited by him at a meeting of the Royal Horticultural Society (see fig. 48), while the specimens shown in our illustration at fig. 47 were received from Mr. Willy Müller, of Naples.

This species was originally collected by Buchanan-Hamilton in Nepal, but has since been found in many localities extending from Burma to the Western Himalaya, and thence northwards to Mongolia. It is erect in habit and attains a height of nearly 4 feet, having horizontally spreading branches. The slender, flattened phylloclades are about $\frac{1}{2}$ inch long and are borne in clusters of about five, as shown in fig. 47. The greenish-white flowers are seated on slender pedicels about twice as long as the phylloclades.

The form known in gardens as var. *Giraldii* (fig. 48) is characterised by its large, broad, glossy green phylloclades, usually borne in groups of five, and the solitary green flowers produced on very slender pedicels much longer than the phylloclades. The flower buds are brownish. This form has been collected in China in the province of Shensi by Pere Giraldi and in Szechuen and Hupeh by Dr. Aug. Henry.

The species is a very variable one, and three varieties of it are enumerated in Hooker's *Flora of British India*, vi. 315, but the variety *Giraldii* has larger phylloclades than either of these. *C. H. W.*

FRUIT TREES ON WALLS.

THE crop of fruit from wall trees is, this year, very meagre. Peaches and Nectarines in these gardens were in full bloom on April 21st, when snow fell heavily, and this was followed by 7 $\frac{1}{2}$ of frost at night-time. To obtain the best results from trees against walls, it is necessary, in many districts, to have a glass case or removable lights, so that they can be taken off, especially the front ones. These shelters are, in addition, useful for the culture of vegetables in the early part of the year. The Peach wall in these gardens is about 250 feet long and 15 feet high; the dull season last year was detrimental to the well-ripening of the shoots of the trees planted against this wall, and the trees were attacked with mildew and leaf-curl. When this was apparent, they were sprayed with "Medela," and this stopped the spread of the mildew on the wood, and, to some extent, the leaf-curl also. This specific was tried on Black Currants for mildew with good results; it was applied in both cases after the fruits were gathered. For exposed positions on walls we find Apple and Pear trees trained on the

cordon system more profitable than Peaches and Nectarines, but the trees need root pruning and lifting about every two or three years. Figs are even more profitable than Apples or Pears; trees planted here against a south wall always yield a crop: Brown Turkey succeeds best. The soil is very heavy in texture, and before the trees were planted a large trench was dug out, the bottom concreted, and the hole filled in with richer, lighter soil. Although these Fig trees received no protection in winter, they have fruited well this season. The shoots of out-door Fig trees should be trained thickly, as they protect each other from the effect of cold winds. In the spring some of the longer useless growths are cut clean out from the base of the tree. If the fruits are required early, the shoots should be stopped at the second leaf, but this will mean losing the fruits on that shoot for next season. The other shoots should be allowed to develop five or six leaves if the tree is strong, but these should not be stopped too early, as this will induce the young fruits to develop this autumn, only to be cut back by frost in winter. St. Johns is useless on walls in the open here. Violette Sepor develops an excessive amount of wood, and no amount of root pruning or stopping of the shoots will induce fruiting. Negro Largo ripens too late, but fruits that do mature are

scarlet, and the growth has the same vigorous habit as "Miss Willmott," which is now too well known to need a description. It is many years since I saw the large exhibition specimens of Verbenas in pots, but my memory is fresh on the point of their beauty. It has been suggested that the *Verbena* lost vigour through being propagated in heat, but I think it more than probable that the selection of fine flowers without regard to habit of growth has had more to do with this loss of constitution. The vigorous growth of the two varieties referred to should bring the Verbenas into general favour again. A large collection of colours is not desired, but there is room for a white, also a purple-coloured variety having the same habit as Miss Willmott; this beautiful variety sells freely in the market, and the market prices vary from 6s. to 15s. per dozen. Mr. Sweet grows it in very fine condition; also the scarlet variety named King of Scarlets, which I believe to be the same as Miss Willmott's "Warley." It is hardly necessary to state that these varieties are equally suited for bedding as for pot culture. I have not yet seen much of the scarlet kind used for bedding, but the pink variety forms one of the most beautiful of flower beds. The chief difficulty in the culture of Verbenas is in keeping the stock clean and healthy during the winter. The best method, according to my

FIG. 47.—ASPARAGUS FILICINUS, FROM SPECIMENS RECEIVED FROM MR. MÜLLER.

good in size and flavour. Even on east walls, Brown Turkey does well: it withstood 20 of frost without protection, and ripened a good crop of fruits. The covering of Fig trees in winter tends to make the shoots tender and unable to resist the cold springs after they are uncovered. Cherries are a very uncertain crop in any position on clayey soils, but the crop this year has been the best for several seasons. The roots need to be kept close to the surface of the soil, otherwise the trees gum and crack, and their growth is very slow. Morello Cherries generally give good returns. Plums are good; unfortunately, we have not many wall trees. Kirk's, Golden Drop, Jefferson's, and Gages are all good. *A. B. Wadd, Paddockhurst Gardens, Sussex.*

FLORISTS' FLOWERS.

THE VERBENA.

THE fine pink variety Miss Willmott has been cultivated for two or three years, and has proved a most useful market plant. Warley is another good variety, and, like the one already mentioned, was raised by Miss Willmott. The flowers of Warley are coloured a rich crimson-

experience, is to raise them from cuttings in August. These will root best on a hot-bed that has been made some time, and is therefore not too hot, but with a falling temperature. Cuttings struck in August have time to become established before the winter arrives. Some growers depend upon spring-struck plants and keep them in pots through the summer. They require a position in winter free from frost, but one that is cool and fully exposed to the light. If kept cool and dormant, they will start into growth freely when placed in warmth about the middle of February, and will soon furnish new shoots for cuttings. The stock plants should be dipped into some insecticide before starting them in heat, as this will ensure clean cuttings, which will root freely if inserted in an ordinary propagating pit. The plants should be removed from the pit before they become spindly. Later the tops may be taken off the longest shoots, and these will furnish a further batch of cuttings. In growing Verbenas in pots, the main requirements are a rich compost, a light, airy position, and regular stopping of the shoots until they have made bushy plants. Three or more plants may, if required, be grown together in one pot. When the flowering pots are well filled with roots, manure may be applied freely. *A. Hemsley.*

NOTICES OF BOOKS.

*** THE PERFECT GARDEN.**

The leading note of this book is that of colour grouping; and combined with this matter are practical hints on economical management, and the culture of all the principal flowers, fruits and vegetables.

The book commences with a prologue on dream gardens, a phantasy in which rambler and other climbing Roses and Sweet Peas figure largely, together with brief references to gardens in Cornwall and Holland with which the author was enchanted. The first chapter is entitled the "Soul of the Garden." According to the author, a beautiful garden represents the sum of idealised human effort on practical lines. We wonder how much of this ideal is represented in the works of the best landscape gardeners, without mentioning those of the ordinary practitioners of the craft? In gardens, he states, is expressed what the flower lover is unable to express in painting or in poetry. In a sense, we are all

tions of owners and their gardeners. As a matter of course, the author does not favour in the least degree the employment of tender exotics in the flower garden, but bestows his commendations on hardy perennial plants, at the same time expressing a fear that the present system of massing these plants according to colour will result in similar uniformity and formality to the bedding-out system they were chosen to supersede. As yet, however, there does not seem to be any danger of this undesirable alteration taking place. The author favours the methods pursued at the Royal Gardens, Kew, with hardy plants, that is, fairly wide planting in masses.

It is suggested that the owners of gardens should take charge of the floral arrangements in their gardens with the view of introducing an improved system; but first they must disabuse their minds of the idea that artistic flower gardening can be picked up as easily as a dropped stitch in Limerick lace; on the contrary, it needs earnest and intelligent study, and they must know their plants and the best modes of

Bryanstone House, Dorset, that is, with a broad border planted with hardy subjects with climbing plants on the terrace-retaining wall.

Exterior hedges and various kinds of fences are discussed; and the folly of making a rockery in a part of the garden which is not suitable for such a feature, is pointed out. Much useful information is afforded about laying out a new garden in a chapter entitled "The Conquest of the Wild." In the chapter "Colour for all Seasons," simplicity in the planting is rightly insisted on, as being the chief factor in art, and it should be the "Soul of the garden." In flower-gardening we are told that colour should be the first consideration, system and design being separate things, and colour unites them. We see in this phrase a wish to return to the bedding-out effects of former years, which the author deprecates.

There are chapters on summer-flowering plants, the colours being classed; others follow on autumn, winter and spring-flowering subjects. Colloquially, perhaps, Zonal Pelargo-

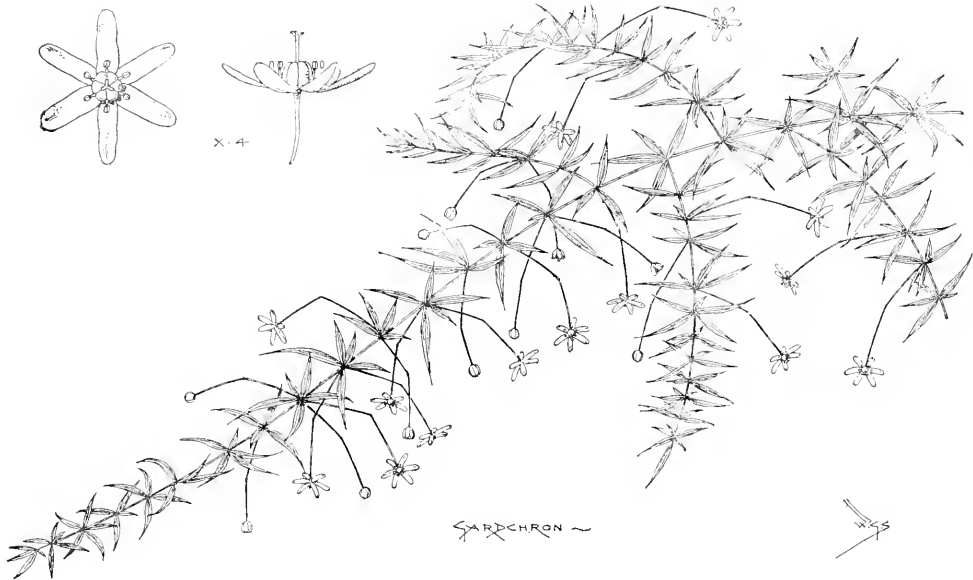

FIG. 48.—*ASPARGUS FILICINUS* VAR. *GIRALDDII*, AS EXHIBITED BY SIR TREVOR LAWRENCE, BART.

gardeners to-day; and cultured persons talk of gardening as they talk of books, paintings and music. A knowledge of gardening is a part of education; but the making of a garden tests the depth of education.

In regard to design and the home-made garden, the author states that we have been swayed by design; which is to the landscape gardener what the crown is to the monarch, the symbol that impresses the multitude. The landscape gardener's plan is not our garden—the garden of our dreams, but a kind of foster child, that we may entertain affection for some day. However, there are gardens in this country so beautiful and so satisfying to our minds which the fortunate owners would not exchange for any other in any part of the world. And these are mostly the works of landscape gardeners, added to by, probably, genera-

employing them. We trust the head gardeners will do all that is in them to keep to the fore and not abrogate their functions through lack of ability. Many of them have taken lessons from the fine displays of hardy plants at the R.H.S. meetings, and at Shrewsbury, Edinburgh, York, and other towns.

If changes must be made, the author advises that these should be in the nature of experiments carried out in a "reservation." He observes that a person who may be totally unacquainted with the Elizabethan, Italian, French, and Dutch schools of garden design, could make a beautiful and productive garden. We should add that he might compass something satisfactory enough in a way if he had a knowledge of plants, their habits and preferences in the matter of soil, aspect, &c. We are told in what manner formality may be excluded from a garden surrounding a dwelling built on a hill; how, if a terrace be made on the garden front, the wall may be masked by plants, as, for instance, at

niums are Geraniums, but as the correct botanical names are used for most of the other plants, why not for these? A little slip occurs on p. 119, where Watts is named, instead of Mr. Holman Hunt, as being the painter of the celebrated "Light of the World." Roses of most kinds and varieties are treated of in a lengthy chapter, great stress being laid on those ephemeral rambler Roses that mostly make a big show for a short time in the summer, and are no more seen till the next one. The author recommends in the planting of Rose beds with dwarf Roses, to employ one colour per bed.

There are remarks on flowering bulbs, corms, and tubers; on fruit culture out-doors and under glass, select lists being given in reference to the cultivation of fruit in all parts of the country. There are many illustrations in the book, the reproductions from photographs being especially good. The professional gardener, no less than the amateur, will find that the book contains useful matter of a suggestive character. *M.*

* *The Perfect Garden*, by Walter P. Wright. Dims. 8vo., pp. 406. Published by Grant Richards, 7, Carlton Street, London, S.W.

FLOWERS OF SPENSER.

(Continued from p. 104.)

PEAS.

The vaulting Poets found nought worth a peaunt.

Shepherds Calendar, October.

"Not worth a peaunt" was in Spenser's time and long after a common proverb of worthlessness. As a delicate vegetable it was very little, if at all, known in his time.

PENTHA.

The Gods pitying this paire of lovers trew, Transformed them there lying on the field Into one flower that is both red and blew; It first growes red, and then to blew doth fade,

Like *Astrophel*, which therewith was made. And in the midst thereof a Star appeared, As fairly formed as any star in shyes; Resembling *Stella* in her freshest yeares, Forth darting beames of beaute from her eyes;

And all the day it standeth full of dew, Which is the teares, that from her eyes did flow.

That herbe of some Starlight is cald by name,

Of others *Pentha* though not so well; But thou where ever thou doest find the same.

From this day forth do call it *Astrophel* *Astrophel, 181-190.*

In all Spenser's works there is no flower described at such a length and so minutely as this; yet it is impossible to identify it. There is no such plant-name as *Starlight* or *Astrophel*, and there is no Greek or Latin name like *Pentha*. The *Aster* and *Speedwell* have been suggested, but they are mere guesses. (See *Astrophel*.)

PERCELAINE.

Fat *Coleworts*, and comforting *Perseline*, *Maipotmos.*

Perceleine is an obsolete form of *Parlsy*, *Parselaine* or *Parsnip*; but most likely *Parsley*.

PINE.

1. The sayling Pine. *F.O., I. i. 8.*

2. Here also grew the rougher-rinded Pine, The great *Argoan* ships brave ornament;

Decks all the forest with embellishment, *Virgils Gnat, 27.*

Spenser probably never saw any *Conifer* except the *Scotch fir*, for the large number now grown in England have come to us since his day. By "sayling Pine" he means to show its use in shipbuilding.

PINKS.

1. Bring hether the Pincke and purple Cul-lambine. *Shepherds Calendar, April.*

2. Her lovely eyes lyke Pinckes but newly spread. *Sonnet, 64.*

(See *Carnations*.)

PLATANE.

And the *Platane* round. *F.O., I. i. 9.*

The *Platane* is the *Plane* tree; it is not a native tree but is said to have been introduced into England by *Bacon*. If that is so, Spenser may have seen young trees; but his knowledge of the tree was probably only derived from Greek and Latin writers, especially *Pliny*. The epithet "round" may apply to the pretty globular fruit; but it is doubtful.

POPLAR.

1. The Poplar never dry. *F.O., I. i. 9.*

2. And in her hand a Poplar branch did hold *F.O., II. ix. 37.*

3. Least that the Poplar happily should open Her brothers strokes. *Virgils Gnat 28.*

4. Alcides' speckled Poplar tree. *An Elegie, 13.*

All the passages have more reference to the classical account of the *Poplar* than to the English species. The "never dry" of the first passage certainly refers to the legend that the sisters of *Phaeton* were turned into *Poplars* and were perpetually weeping for his death (*Ovid, Metam. II*).

POPPY.

1. Dead sleeping Poppy. *F.O., II. vii. 57.*

2. Dull Poppy. *Maipotmos.*

Spenser could not have been a great observer of the British wild flora if he could find no better epithet for the *Poppy*—the most brilliant and pure-coloured of all European plants—than "dull" and "dead." But it is very possible that it is now so abundant in his days as it is now. Turner, describing it in 1548, does not mention it as wild, but says "it groweth sowed in gardines."

PRIMROSE.

1. She is the pride and primrose of the rest. *Colin Clout, 310.*

2. Primroses greene. *Shepherds Calendar, April.*

3. She is the Rose, the glory of the day And mine the *Primrose* in the lowly shade. *Daphnoida, 231.*

There were green *Primroses* in Spenser's day as there are now, grown occasionally as curiosities, but I should scarcely think that Spenser would have chosen them for the coronet of "faire *Elisa*." I suppose he referred to the fresh green leaves.

QUEEN APPLES.

1. Queene apples and red cherries from the tree. *F.O., Canto VI.*

2. Then would I seeke for *Queene-apples* unripe. *Shepherds Calendar, June.*

I am unable to identify these with any known variety of the *Apple*. It may only mean the earliest fruit.

REED.

And on a broken reed he still did stay His feeble steps. *F.O., III. xii. 11.*

The reed is the recognised emblem of weakness and instability.

RHODODAPHNE.

Fresh *Rhododaphne* and the *Sabine* flower *Virgils Gnat, 54.*

Spenser copied this name from *Pliny*. It is the *Oleander*, of which he could have had no personal knowledge.

ROSE.

1. Wyde was the wound, and a large luke-warm flood Red as the *Rose*, thence gushed grievously. *F.O., II. viii. 30.*

2. No other tire she on her head did weare, But crowned with a garland of sweet *Rosiere*. *F.O., II. ix. 19.*

3. The *Prince* by chance did on a lady light, That was right faire and fresh as *Morning Rose*. *F.O., II. ix. 36.*

4. Ah! see the *Virgin Rose*, how sweetly shee Doth first peepe forth with bashfull modestie. *F.O., II. xii. 74.*

5. Upon a bed of *Roses* she was layd. *F.O., II. xii. 77.*

6. As hee that hath espide a *Vermeil Rose* To which sharp thornes and bresses the way forestall. *F.O., III. i. 46.*

7. Amongst the *Roses* grow some wicket weeds. *F.O., III. i. 49.*

8. Shee bath'd with *roses* red and violets blew. *F.O., III. vi. 6.*

9. Fair *Cance* as fresh as *morning Rose*. *F.O., IV. iii. 57.*

10. As *roses* did with *Lilies* interlace. *F.O., V. iii. 23.*

11. Like as a tender *Rose* in open *Plaine*. *F.O., V. vii. 15.*

12. Shee mote perceive a little purple mold, That like a *Rose* her silken leaves did faire unfold. *F.O., VI. xii. 7.*

13. A *Virgin* brides adorned head With *Roses* dight and *Goolds* and *daffadillies*. *Colin Clout, 338.*

14. Whose beautie shyneth as the morning cleare, With silver dew upon the *Roses* pearling. *Colin Clout, 500.*

15. Upon her head a *Cremosin* coronet With *Damaske Roses* and *Daffadillies* set. *Shepherds Calendar, April.*

16. In the red *Rose* medled with the *White yere*, In ether cheekie *depeincten* lively chere. *Ibid.*

17. *Girlonds* of *Roses* and *Soppes* in *Wine*. *Shepherds Calendar, May.*

18. And round about he taught sweete floweres to grow The *Rose* engrained in pure scarlet die. *Virgils Gnat, 84.*

19. And hee like *Gods* in *Yvory* beds arrayd, With *rose* and *lilies* over them displayed *Hymnes, 285.*

20. Sweet is the *Rose*, but grows upon a breere. *Amoretti, xxvi.*

21. *Fayre*, when the *rose* in her red cheekes appeares. *Amoretti, lxxxii.*

22. *White* as the *Rose*, before the *luxure* Which *Venus* blood did in her leaves im- presse. *Daphnoida, 108.*

23. She is the *Rose*, the glory of the day. *Daphnoida, 231.*

24. And kisse thy lips like faded leaves of *rose*. *Astrophel, 158.*

25. The *rose* and *lillie* have their prime, And so hath *beaute* but a time. *An Elegie, 137.*

26. And compast all around with *Roses* sweet. *Clorinda, 70.*

27. Her ruddy cheekes like unto *Roses* red. *Amoretti, lxxv.*

28. The *roses* rainging in the pride of *May*. *Maipotmos.*

29. A *bower* appareld round with *divers roses*, Both red and white. *Eritains Ida, Can. ii.*

30. Few *roses* round about were scattered. *Ibid., Can. iii.*

In all these thirty passages there is nothing to show that Spenser had any deep affection or even admiration for the *Rose*; or nothing like the delight with which *Chaucer* and *Shakespeare* speak of it. In many of them the *Rose* is merely a colour, especially the colour of a lady's cheek; in others it is the accepted poetical type of beauty. In one passage only—No. 15—is a special *Rose* in his mind, it could scarcely have been either of our British wild *Roses*, beautiful though they are; he must have been thinking of some of the foreign garden sorts, of which many were cultivated in English gardens in his day.

ROSEMARY.

1. Shee secretly would search each dainty hie, And throw into the well sweet *Rosemaries*. *F.O., III. i. 36.*

2. The *Marigolde* and cherifol *Rosemarie*. *Virgils Gnat, 84.*

3. The knotted *rush-rings*, and gilt *Rose-maree*. *Shepherds Calendar, November.*

4. *Colde Lettuce* and refreshing *Rosmarie*. *Maipotmos.*

Though a foreign plant, chiefly from Southern France, the *Rosemary* was a favourite in English gardens from its easy growth and pleasant, abiding scent. The last quotation shows that Spenser knew the right derivation of the word; it is *ros marinus*.

RUE.

1. Th' aged *Nourse*, her calling to her bowre, Had gathered *Rew* and *Savine*. *F.O., III. ii. 40.*

2. Feede ye henceforth on bitter *Astrefol*, And striking *Smallage*, and *musavere Rew*. *Daphnoida.*

3. Rank-smelling *Rue*. *Maipotmos.*

Rue is the accepted symbol for long-enduring bitterness. *H. N. Ellacombe.*

(To be continued.)

JAPANESE IRISES.

THE species of *Iris* indigenous to Japan are not numerous, but as is the case in so many plants that have become favourites with the Japanese, the forms of one species are overwhelming in number, and it is now common usage, in gardens, at least, to regard Japanese Irises as beginning and ending with *I. levigata*.

There are several species that can well be grown in English gardens, and their omission from collections of hardy flowers is due in some measure to the common belief that all grassy beardless Irises need sites very near to water

species (*I. sibirica*) has its finest form in Japan. There is much to learn in the cultivation of the rarer Japanese Irises, whilst in the case of older species there is much to unlearn. The familiar *Iris levigata* or *Kämpferi*, for instance, grows well enough for a year or two, but in some gardens finally disappears after some such period.

SPECIES AND VARIETIES.

I. ALBO-PURPUREA.—A rare Japanese species of merit that thrives best with its root-stock just below the water-level. It is a lovely plant of the *levigata* type, but the leafage is purplish near the root-stock—a character shown in the

beautiful. I attempted to grow *I. albo-purpurea* for a long time in the plant border, entirely ignorant of its moisture-loving character; the plants made a little growth, but were evidently unhappy. An importation from Japan put me on the right track. A bluish loam one always associates with submerged conditions, and the presence therein of a water beetle showed the clumps had been under water for years. My strongest plants are now covered with half-an-inch of water always.

I. DELAVAYI.—Although a Yunnan species, this *Iris* is now commonly cultivated in Japan, and may fittingly be grouped with Japanese species on cultural grounds alone. It has narrow, grassy leafage 2 feet long, and tall, slender stems 4 feet high, bearing four to six flowers that are coloured a rich violet, and have small spots of white on the falls. The close resemblance of the flowers of *Iris Delavayi* to those of the bulbous *I. reticulata* is extraordinary; in colour and shape they practically agree, and one may well describe them as enlarged *I. reticulata*. I have noted the species in various gardens in Great Britain under varied conditions, and the finest specimens were by waterside—their roots in 6 inches of soil above the water level. They enjoy liberal feeding always, and the species should prove one of the best grassy Irises for waterside grouping; its novel colouring and exquisite form attracts attention at once. It flowers in July.

I. ENSATA.—A rampant-growing, grassy *Iris*, that proves none too good for the choice plant-border. Forms of it are numerous, and of these *ALBA* and *OXYPETALA* are best. The leaves are in a loose tangle a yard long, and often many yards in area. The flowers are produced on stout, flexuose stems, much shorter than the leaves, and are often quite hidden by them. They are coloured shades of lilac, but are quite inferior to the Asiatic species *Guldenstediana* for gardens; the petals are narrow, lined with green, the lip petals only being attractive. A series of hybrids between this species and many other grassy Irises contained some pretty flowers that should prove very useful. They were growing in the late Sir Michael Foster's garden, and had been established for years. I do not know of any hybrids raised in Japan.

I. GRACILIPES.—In many respects this *Iris* is one of the best "finds" in recent years. It belongs to a little group, of which *terciorum*, *japonica*, and *cristata* are examples, and has perhaps the slenderest growth of any *Iris*. The flowers last in good condition throughout May and June, and the foliage is a very attractive patch always. *I. gracilipes* (see fig. 49) is representative of all that is good in dwarf Irises, and if it could be depended upon to survive our worst winters, would speedily become popular. It has many branched running rhizomes, broad, fan-shaped tufts of grassy leaves 6 inches high, and very slender flower-stems, that are produced separately from the leaf-growths. The flowers are circular in outline, as large as a florin, and are perfect models of *I. terciorum* on a small scale. The petals are coloured palest lavender, and are tinted with yellow at the bend of the blade. It is an ideal rock-plant for a rather dry site in the south-western counties; for the remainder of Britain it must have frame protection. It flowers in May, and my experience shows the plants dislike disturbance exceedingly, and should only be moved when in a state of growth.

I. JAPONICA (I. CHINENSIS).—This is a delightful *Iris* for the greenhouse, that flowers in the winter season. It has broad leaves in fan-shaped tufts, a running rhizome and slender wiry flower-stems that persist for a long period. The flowers are as large as a crown piece when well grown, and are produced in relays throughout winter. Each flower lasts just one day, and a few days generally elapse before another develops. They are coloured palest lilac, and

FIG. 49.—*IRIS GRACILIPES*: FLOWERS LAVENDER COLOUR WITH SLIGHT YELLOW MARKINGS.

This belief has proved a great drawback to the cultivation of *Apogon* Irises, but Japanese species, embracing plants for the flower garden, the cool-house, the rock-garden, and the water-garden need very careful individual treatment, and those that are really water-loving need moisture in moderation only. Those who have not tried all the Japanese Irises will find them a very interesting group. Each species is abundantly distinct from the others, and the collection consists solely of plants that are exceedingly attractive, even the commonest *A-ni-to*

seedling stages. It grows 2 feet high and produces its flowers in twos from slender sheaths. They are coloured pale sky-blue, and have broadly lanceolate "fall" petals 6 inches long, the standards being just two-thirds this length. Rarely have I seen such a splendid *Iris* and such an elegant flower. The "finish" of petal and delightful poise baffles description—it must be seen to be fully realised.

Var. ovata differs in the diffused blotches of a deeper blue that occur in quantity on the surface of the petals, and it is singularly

have prettily fringed petals tinted with gold at the bend of the blade. This pretty Iris has a peculiar fascination for amateurs, who cannot help being struck by its singular beauty. It is a little difficult to establish, and may not flower for two or three years, but when it reaches flowering stage, it does not relapse. This plant usually succeeds better under the haphazard treatment of the amateur's greenhouse than under more skilled and attentive culture. In my few days I had two specimens of *Iris japonica*—one a splendid specimen of luxuriant growth, but which never flowered; the other a veritable starveling, that eventually flowered itself to death. The vigorous specimen had abundance of water always; the flowering specimen was dry for weeks at a time. A Japanese friend writes: "It does not flower until it has done growing." Presumably the end of the growing season is here meant, but, under cultivation, a debilitated specimen is invariably the most floriferous. Quite young growths should be severed and planted on till they reach flowering strength. Disturbance of an old plant invariably kills it. A few degrees of frost cannot harm the plants, but the hardness of individual specimens varies. G. B. M.

(To be continued.)

The Week's Work.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Ker, Perthshire, N.B.

Violets.—Plants cultivated for flowering in unheated frames during winter should now have their runners layered as advised in a former Calendar. Cut out all the thin and useless runners, leaving only one central one, and placing stones upon this to keep it in position. See that the layers are not allowed to suffer for want of water, but apply occasional waterings with liquid manure, which, if given in the evening, may be watered over the plants. If the leaves are affected with red spider, syringe them thoroughly, holding the syringe low down in order to apply the water on the under surface of the leaves.

Rhododendron (Azalea).—Plants that have set their flower-buds may be placed out-of-doors in a position sheltered from winds, standing the pots on a base of ashes, or on slates in order to prevent worms getting into the drainage material. Whilst these plants are out-of-doors they must be frequently examined in order to see that the roots are not suffering from want of water. The surface soil often appears damp when the centre of the mass containing the roots is dry. Applications of weak Peruvian guano water may be made twice each week during the next month.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. G. L. HARRISON, C.V.O., L.E., Weston, Gloucestershire.

Cattleyas.—Such brilliant weather as we have had recently is very favourable to Cattleyas. The late summer, autumn, and early winter-flowering kinds, are consequently further advanced in growth than is usual at this season. Many of the latter are forming pseudo-bulbs, whilst the earlier kinds are flowering. As I pointed out in a former Calendar, it is from this stage onwards, until the season's growths are fully completed, that more root moisture is needed than at any other season. If possible, the plants should be given more ventilation and exposure to the sun's influence than hitherto, these conditions being necessary to enable them to thoroughly harden and consolidate their new pseudo-bulbs. In some gardens this is more easily accomplished than in others, for a grower who has several divisions devoted to this genus will find it a fairly easy matter to allot portions exactly suitable for his plants, while another, with but a single structure, must collect his plants together and provide for them as best he can in the one house.

Long-bulbed section.—*Cattleya bicolor*, C. Harrisonia, C. granulosa, and their hybrids, C. Pittiana, C. Iris, C. Ashtoniana, C. Mrs. Pitt,

C. Clarkia, and C. Ella, are all charming members of this group, which flower at about the present season. After the flowering period, and when the pseudo-bulbs are fully complete, occasional waterings only will suffice to keep the pseudo-bulbs plump and the foliage healthy. Excessive dryness of the rooting materials, however, must not occur, otherwise the roots will soon perish. The repotting of this section is best performed whenever roots are being made from the base of the youngest growths, and this often happens immediately after the plants cease to flower. Make use of efficiently-drained pots, and a compost of a porous nature, using similar ingredients as previously advised for Cattleyas. Plants of that desirable natural hybrid *Laelio-Cattleya elegans* and its varieties also flower at this time. All those I have mentioned belong to the long-bulbed section, and their cultural requirements are similar.

Cattleya Gaskelliana and C. gigas.—Most plants of these summer-flowering species have passed the flowering stage, and the earliest plants of their hybrids as C. mollis, C. Lord Rothschild and the gorgeous and fragrant C. Hardyana have finished blooming, as many others have done. The present season is the most suitable time to supply new rooting material to those that require it. A cluster of new roots proceeds from the base of the youngest growth almost directly after the flowering period. These soon take a hold upon the new compost afforded, and the

foliage will not shade the fruits. The shoots that are retained should be those which are short-jointed and firm in texture. Thin the fruits to three or four on each shoot. Allow the leading shoots to extend if space permits, as these growths, when well ripened, produce the finer fruit. Old trees carrying heavy crops and that are planted in well-drained borders should be mulched and fed with liquid manure or some other stimulant until the fruits show signs of ripening, after which stage the supply of moisture must be decreased, as an excess of liquid would cause the fruits to split. Care must be taken not to overfeed young trees that are growing freely, or gross and unfruitful wood will be the result. Syringe the trees occasionally on warm afternoons to prevent red spider, and when the fruits are at their ripening stage, tie them in muslin bags, or cover the trees with suitable netting to protect them from wasps.

Raspberries.—As soon as the berries of summer-fruited varieties are gathered, the old canes should be cut away and the young ones required for fruiting next season thinned out to about eight of the strongest: if it is required to thin them still further this can be done next spring. Thin out the canes of autumn-fruited varieties, remove any suckers that appear, and give liberal applications of liquid manure during dry weather.

Apricots.—The earliest of these fruits will now

[Photograph by E. Barnes.]

FIG. 50.—A TOPICAL FLOWER-BED IN THE QUEEN'S PARK, KILBURN.

plants become well established before winter sets in. Root disturbance, however, should be avoided as much as possible, and over-potting strictly guarded against, especially in the case of *Cattleya gigas*, as root-bound plants of this shy-flowering species are always more productive of flowers than others. The success or failure to flower these plants satisfactorily depends largely on the autumn treatment. They must not be allowed to remain dry at the root for any length of time, but should be given a moderate supply of water until such time as the growths have become fully matured and root action has ceased. The aim should be to prevent secondary growths. Should, however, a few break away, as is nearly always the case, it need cause no alarm, and no difference should be made in the treatment of the plants.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The Dowager Lady NUNBURGHOLME, WATER PRIORY, YORKSHIRE.

Fig trees.—Remove all weak and useless shoots to prevent overcrowding of the principal branches, also any suckers that grow from the base of the tree should be taken away. Fasten the young shoots well against the wall, so that

be ripening, and protection should be given them from birds and wasps, as well as from woodlice and earwigs. The fruits can be protected from birds by the use of netting. The other pests are best entrapped with hollow Bamboo canes, &c., before the fruits ripen. These trees, like Peaches, should be kept thinly trained, and all laterals not required for laying in should be kept closely pinched to induce the formation of spurs. If the trees have been syringed occasionally on hot days and the roots mulched and watered, no more water will be necessary after the fruits approach the ripening stage, until they have been gathered. All the trees should then be liberally watered with liquid manure when growing in hot or dry positions, or when vegetables or other crops are planted on the borders. Exception should be made, however, in the case of newly-planted trees. These should have the points pinched out of the leading shoots to encourage more sap to flow into the weaker ones.

Plums.—Plum trees have been badly attacked by aphid this season. Remove all sub-laterals from wall trees, nail in the leading shoots, and wash the trees with soapy water. If the crop has failed, or the trees have already been cleared of fruit, syringe the trees with some insecticide.

THE FLOWER GARDEN.

By W. FIVE, Gardener to Lady WANSLEY, Lockinge Park, Berkshire.

Pillar Roses.—Most of the late varieties have now completed their flowering. It is time, therefore, to examine the bushes and remove at least a portion of the old growths that there may be more space for the young shoots and that these latter will be the better exposed to sunshine. Many of the Wichuraiana Roses and Penzance Briars, such as Meg Merrilies, seed so freely that the removal of the seeds is necessary in order that the plants may make free growth. Among suitable varieties to associate with Crimson Rambler are Dorothy Perkins, Lady Gay, Wichuraiana rubra, Helene, Felicite' Perpetue, Hiawatha, and Psyche. Earlier sorts include Carmine Pillar, Una, Longworth Rambler, Flora, Splendens, and Leuchtstern.

Delphinium.—It is advisable not to allow Delphiniums to remain in the same position for a longer time than two years. After the lapse of this period the quantity and quality of the flowers decrease. The plants may be lifted and divided at any time between this date and the end of October. Small plants with two or more crowns attached, if planted in deeply dug, liberally-manured soil, will commence to grow at once, and make nice plants for returning to the herbaceous borders next March. Apply top-dressings of short manure, and cover the crowns of the plants with coal ashes.

Agapanthus umbellatus.—When large plants established in tubs commence to develop their flower stems they should be given occasional applications of liquid manure. Although the Agapanthus is of comparatively easy cultivation, its free-flowering qualities depend in a large measure upon the treatment given the plants during winter. They need merely to be kept secure from frost, and the roots should only be given sufficient water to keep the leaves in a fresh condition. The plants may remain for years in the same tubs, succeeding well in strong loam with plenty of drainage material, confinement of the roots being favourable to free flowering. The blue Agapanthus, if grown in large tubs and the tubs are plunged out-of-doors, has a very fine appearance with its luxuriant foliage and bold umbels of flowers. The white variety is much less free in flowering, and it loses its foliage altogether during the winter season.

Summer bedding.—During the present month should be taken of any alteration or improvement it will be desirable to introduce into the arrangements for next year. Provided the beds and borders are to remain of the same sizes, it will be a comparatively easy task to require. Remove any superfluous shoots that may have been overlooked on previous occasions, and keep the leaves free from red spider by frequently syringing them. Pot trees very soon exhaust the soil of its nutriment, notwithstanding that manures are applied from time to time; therefore, any trees that require a shift should be re-potted, and the operation should be commenced as soon as the leaves are bearing maturity, and before the roots become inactive. Pots selected for young, free-growing trees should be large enough to admit of a thin layer of fresh compost being placed round the old balls of soil, and each pot should be thoroughly well drained. Carefully turn the trees from their pots, remove the crotches and any soil that does not contain roots, disentangle the outside fibrous roots and shorten long roots that are devoid of fibres. The compost may consist of fibrous loam three parts and wood ashes one part, with some finely-crushed lime rubble

and a little bone-meal added. The compost should be in a moderately dry condition when used, and be rammed firmly into the pot, keeping the roots sufficiently low in the pot to admit of a thin layer of compost being placed over them and soil allowed sufficient space for watering. Following the operation of re-potting, the trees should be shaded from bright sunshine for about one week, syringing them frequently, and subsequently plunging the pots in a bed of ashes in a situation fully exposed to sunshine. Syringe the trees in the afternoon of fine days until the leaves have fallen, and give very careful attention to affording water to the roots.

Selection of trees.—If trees are required to give an immediate return, it will be necessary to select those which are already established in pots, and are well furnished with healthy wood that promises to yield fruit next season. In order to secure such trees, it is necessary to select them early in the autumn. In other cases, where immediate returns are not expected, trees that have been prepared for potting by transplantation and yearly root prunings may be employed. These should be carefully lifted at about the time the leaves are falling and put into pots only sufficiently large to conveniently contain their roots. If these are successfully cultivated next season, and re-potted in the following autumn, they will yield good crops of fruit in 1910.

Luscifrutting trees.—Peach and Nectarine trees cultivated in pots for supplying late crops of fruit should be assisted with applications of liquid manure up to the time the fruits commence to ripen, syringing them frequently during the same period. The syringing must be discontinued whilst the fruit is ripening, but it should be resumed directly the crop has been gathered.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

General work.—The work will not be so pressing now as it has been recently, for most of the crops cultivated for winter supply will be fast maturing, and later crops are sown or planted in their winter quarters. The ground should be cleared of all weeds and rubbish, which should be consumed on the smother fire, and everything made to appear as tidy and workmanlike as possible, for there is no reason why the kitchen garden should not only be a source of profit, but also pleasing in appearance. Should dry weather continue, liberal waterings should be given to many of the growing crops, so that these may be enabled to complete their growth and yield abundantly.

Endive.—Where salads are in demand all through the winter, there is no more desirable plant to cultivate than Endive, but to ensure a continuous supply it is important that frequent small sowings be made during the next three or four weeks, the last being made in an unbeated frame. Continue to put out plants raised from earlier sowings as they become ready, selecting a site facing either to the south or west, and composed of rich soil. The plants should be put at distances from each other of 12 to 15 inches each way, and frequent waterings may be required during the next few weeks.

Letuce.—This crop should be treated much in the same manner, selecting for sowing those varieties which have proved to be most hardy. The finest Coe variety known to me is 'Hick's Hardy White.' A good variety of Bath Coe is also desirable, but this requires more time and is not so good in quality. For a Cabbage variety one of the best is a true stock of the old Hammersmith, this being one of the hardiest Lettuces ever raised.

Globe Artichokes.—Cut the heads of these immediately they become of sufficient size. If they are more abundant than is required for present use, put them with their base in water and in a cool place. In such conditions they will keep for a fortnight, provided the water is changed occasionally and small pieces cut off the stem of the Artichoke. The plants may be given occasional drenchings with liquid manure from the farmyard; they will then continue to produce fresh heads until quite late in autumn.

Parsley.—Make a liberal sowing in an unbeated frame during the next few days, and if possible on a sussed hot-bed. Plants raised

from a sowing at this time and in the conditions frequently prove valuable during severe weather in winter. Thin out and transplant Parsley that has been raised by late sowings in the open. It is a good plan at this season to plant a row at the foot of a south wall or close fence, putting the plants 6 inches apart from each other.

Sweet.—This vegetable is more generally appreciated than formerly. The same plantation, if well made in the first instance, will last in good condition for a number of years. The flowering shoots should be cut off, and help to the roots may be afforded by applications of liquid manure or some chemical manure specially suited for vegetables.

Cabbage.—Make a liberal sowing of seeds on a site having a southern aspect.

THE APIARY.

By CHELERS.

Foul brood.—Of all diseases among bees "foul brood" is the most common and difficult to deal with. The disease has become very common, since queens have been so largely imported. The first point a beginner can detect is the disagreeable odour which is noticed as soon as the bees are removed. The cappings over the brood, which should, in a healthy state, be nicely rounded and convex, are indented and perforated with small holes and the comb of a distinct coffee colour. If any doubt exists, take a match and insert one end in a cell, and on withdrawing same the contents of the cell will adhere and have a ropy look. It is the larvæ that are attacked by the disease, and soon die in the cells and rot. The disease is caused by a germ, and therefore the beekeeper himself cannot too carefully disinfect himself and appliances before examining healthy stocks. In the early stages of the disease its spread can be fairly easily prevented. The remarks on cure only apply to a really strong stock, for if the colony be weak it is best to destroy it, and all that has been in the hives, including frames and comb quilts, and then thoroughly disinfect the hive by painting it all over with a solution of strong carbolic acid; when the smell has evaporated, the hive may be used again. Before painting the hive with acid, it ought to be washed well with boiling water. If the stock be strong, then shake the bees off the combs and confine them in a well-ventilated straw skep for 48 hours. Fit up some frames with foundation, and shake out the bees on a cloth and let them run into their new home. Burn the cloth and straw skep at once. Give the bees good syrup, and confine them on about five or six frames, keeping them warm by supplying good quilts.

Wasps.—In some parts of the country wasps are a great source of worry to the beekeeper as well as the gardener. The weak hives are first attacked, and if a little aid be not given the inmates, they will soon be robbed of all their stores, for the wasps descend upon such hives in great force. The entrances must be closed so that one bee only can enter or leave at a time. A beekeeper, whom I met, was so troubled by the attack of wasps that he tried every known device, and at last fed the bees on syrup containing whisky. He said his bees then fought furiously, and repelled the attacks. Whether this is true or not I do not know, for the man was a stranger to me, but undoubtedly a keen beekeeper.

Uniting bees.—Where late swarms or casts are considered too weak to winter successfully, then two or more stocks must be united so as to form a colony for next year. Bring the colonies to be united gradually together, about a yard nearer each evening, i.e., if the bees have been on the wing during the day. When the hives are close to each other, decide which hive is to hold the bees, then puff smoke into the entrance of each stock, and permit the bees to gorge themselves; this done, remove the outer and puff in a little smoke again between the combs, and as you lift out the frames flour each lot of bees with the flour dredger and place the frames alternately, keeping all brood in the centre and destroying all but one queen, if the others are not required elsewhere. By dusting the bees with flour all of them have the same scent, and they generally unite without further trouble.

FRUITS UNDER GLASS.

By T. COOMBE, Gardener to LORD LANGRATTOCK, The Hendre, Monmouthshire.

Peach and Nectarine trees in pots.—Trees that have supplied an early crop of fruit and have already completed their growth may be removed to a sheltered and sunny position out-of-doors, where they may be expected to perfectly mature their wood. Remove any superfluous shoots that may have been overlooked on previous occasions, and keep the leaves free from red spider by frequently syringing them. Pot trees very soon exhaust the soil of its nutriment, notwithstanding that manures are applied from time to time; therefore, any trees that require a shift should be re-potted, and the operation should be commenced as soon as the leaves are bearing maturity, and before the roots become inactive. Pots selected for young, free-growing trees should be large enough to admit of a thin layer of fresh compost being placed round the old balls of soil, and each pot should be thoroughly well drained. Carefully turn the trees from their pots, remove the crotches and any soil that does not contain roots, disentangle the outside fibrous roots and shorten long roots that are devoid of fibres. The compost may consist of fibrous loam three parts and wood ashes one part, with some finely-crushed lime rubble

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly sealed by the writer. If desired, the signature will not be printed, but left as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to print for any contributions or illustrations, or to return unacknowledged communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but no account is responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, AUGUST 15—Sandway and Dist. Fl. Sh.

TUESDAY, AUGUST 18—

Roy. Hort. Soc. Com. meet. British Gard. Assoc. Ex. Council meet. Brighton Fl. Sh. (2 days).

WEDNESDAY, AUGUST 19—

Shropshire Hort. Soc. Exh. at Shrewsbury (2 days). Hemel Hempstead Fl. Sh.

THURSDAY, AUGUST 20—

Roy. Hort. Soc. of Aberdeen Sh. (3 days). Oxford Autumn Fl. Sh.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last FIFTY Years at Greenwich—61.7°.

ACTUAL TEMPERATURES:—

LONDON.—(Wednesday, August 12 10 P.M.): Max. 67°, Min. 49°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—(Thursday, August 13 10 A.M.): Bar. 29.9; Temp. 60°; Weather—Overcast.

PROVINCES.—(Wednesday, August 12 6 P.M.): Max. 62° Bury St. Edmunds; Min 54° Scotland, East.

SALES FOR THE ENSUING WEEK.

MONDAY NEXT—

Trade Sale of Dutch Bulbs at 10, Lillium Harrisii, L. longiflorum, Narcissus, Palm seeds, &c., at 5, at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

THURSDAY NEXT—

Trade Sale of Dutch Bulbs by Protheroe & Morris, at 67 and 68, Cheapside, at 10.

Treatment of Unknown Vegetable Products.

The recent appearance in the London drug market of some fourteen bags, each weighing, it was said, three-quarters of a hundred-weight, containing unknown roots from Colombo, has drawn fresh attention to the fact that such unknown articles of commerce are frequently introduced in this way, and, finding no buyers, as in this case, are lost to commerce. The "roots," which were so classed in the broker's catalogue, proved to be those of *Coscinium fenestratum*, a Menispermaceous climbing plant of Ceylon and Southern India. It is noted for its bright greenish-yellow colour when freshly cut, as well as for its very broad medullary rays. It is sometimes known as False Columba, and has been used as a substitute for true Columba, which is the root of *Jateorhiza Columba*, a climber of the forests of Mozambique. Both in India and Ceylon the root of the *Coscinium fenestratum* has been spoken favourably of by many writers on medicinal products, and it is said to be now official in the Indian *Adendum* of the Pharmacopœia, besides which, the yellow colouring matter is used as a dye. A letter in a recent issue of our contemporary, "The Chemist and Druggist," written by an

authority on drugs, comments on the practice that prevails at the English drug auctions of consigning new, or unknown products, which fail to find buyers, to the rummage sales, or the dust destructor. "While the Hamburg shippers and German drug houses," he says, "are careful to get supplies of out-of-the-way drugs, in this country it is quite a matter of chance for a new, rare or unrecognized product to even get catalogued correctly, so that new products, whether drugs or other articles, get but little chance of being known or tried." New uses are constantly being found for products that a few years ago were considered of no value, and it is, therefore, important that an expert opinion as to

so that when roasted, as they usually are before being sold, they are perfectly wholesome. The tree belongs to South America and the West Indies, but it has long been established in India, the bulk of the shipments received in England having been obtained from Bombay. Large quantities of these so-called nuts are now annually exported from the East Coast of Africa, namely Zanzibar, Inhambane, Beira, Quillimane and Delagoa Bay to European ports. The Bombay shipments to England mostly come in the shelled form, that is, the kernels are removed from the outer shell, which is hard and woody. It is further stated that Madras is now sending to England large quantities of these shelled and

FIG. 51.—RHODODENDRON [RHODOFAMNIS] KAMTSCHATICUM; FLOWERS CARMINE PURPLE, FROM SPECIMENS EXHIBITED BY MR. G. REUTHE.

the sources and properties of unknown articles should be obtained before these are offered for sale. It could then be determined whether the article could be turned to any good purpose, or whether its use was only as a substitute for any other well-tried substance.

Bearing upon this subject is the increase that has recently taken place in the importation of Cashew nuts, the fruit of *Anacardium occidentale*. As edible nuts they have hitherto been but very little in demand in this country, their unpopularity being probably due to a great extent, to the presence of an acrid juice between the shell and the kernel itself. This, however, is dissipated by heat,

blanched kernels. Considering that these Cashew nuts realise in the Mincing Lane market from 19s. to 24s. per cwt., there is apparently a new development of their use springing up.

A reference to the Cashew nut would not be complete without noticing the peculiar habit of the plant in the production of its fruit. The so-called nut, which is kidney-shaped and covered with a hard shell, is borne at the top of a pear-shaped, fleshy receptacle or swollen stalk, which, when fully grown, has a reddish tint and is edible, having an agreeable, acid taste, the acrid juice only surrounding the kernel.

OUR SUPPLEMENTARY ILLUSTRATION is from a sketch by Mr. WORTHINGTON SMITH of *Rose Refulgens*, to which an Award of Merit was granted by the Floral Committee of the Royal Horticultural Society on June 23 last. It is a hybrid Sweet Briar, probably crossed back again upon a Rose, as the foliage has little resemblance to that of the Sweet Briar, and the flowers are large, being 3½ inches in diameter. The purplish-crimson blossoms are produced in clusters, the individual blooms often numbering twenty in one truss. The flowers are the more ornamental by reason of the golden-coloured stamens, and a whitish ring round the centre of the petals. A large plant furnishes a fine effect, and, owing to its vigorous growth, the variety is adapted for planting as single bushes or in

BOTANICAL MAGAZINE.—The issue of this work for August contains illustrations and descriptions of the following plants:—

CESALPINIA JAPONICA, tab. 8207.—This species was figured in the *Gardeners' Chronicle*, November 3, 1888, p. 513, from specimens obtained from the Coombe Wood nursery of Messrs. JAMES VEITCH & SOXS, before the species was distributed. Since Mr. GEORGE NICHOLSON wrote the note which accompanied the illustration on that occasion, the species has been in cultivation at Kew for many years, and Mr. W. WATSON, now writing in the *Botanical Magazine*, states that the plant is only hardy in sheltered positions in the south of England, and that the plant from which the present plate was prepared is one of a group established in

distributed in the North-western Himalaya, 8,000 feet from Hazara, where it was first collected by Dr. J. L. STEWART, and Kashmir, where it was originally obtained by Mr. V. JACQUEMONT, to Kamaon, where it was first seen by Dr. T. THOMSON. The species is very closely allied to *f. atropurpurea*, which is met with, as a rule, at a slightly lower elevation, since it extends to Indo-China, and is believed to occur also in Southern China. The plant forms a shrub of considerable size, with branchlets at first sparingly beset with adpressed hairs, which soon become glabrous. The leaves are alternate, 1½ to 2 inches apart and 7 to 8 inches in length, including petiole. Leaflets, 5 to 9, varying occasionally to 11. The flowers are produced in axillary racemes 3 to 8 inches long and bearing

FIG. 52.—*EUCRYPHIA CORDIFOLIA*: FLOWERS WHITE.
(See "Botanical Magazine")

rows for hedges. The foliage and shoots are handsome, the former being of a rich dark green colour, and the latter having ruby-red prickles. The plant to which the Award was granted was shown by Messrs. Wm. PAUL & SOXS, Waltham Cross.

ROYAL HORTICULTURAL SOCIETY.—A meeting of the Committees of this Society will be held on Tuesday next, August 18, in the Royal Horticultural Hall, Vincent Square, Westminster. In the afternoon a lecture on the "Cultivation of Figs in Pots" will be delivered by Mr. JAMES HUDSON, V.M.H.

a recess under the south wall of the Temperate House at Kew, where it has grown practically uninjured by frost for about five years. One of the largest specimens in cultivation is in the garden of Lord BAKERMORE, at Fota, near Cork, and this plant flowers freely every year. The present description is by Mr. T. A. SPRAGUE, who states that the racemes are much laxer in *C. japonica* than in *C. septaria*, which it most resembles, and the pedicels are longer, whilst the uppermost petal has red markings, which apparently do not appear in *C. septaria*.

INDIGOPERA BEBEPELAVA, tab. 8208.—This plant is described by Lt.-Col. PRANK. It is widely

distributed in the North-western Himalaya, 20 to 40 flowers each. The corolla is dark crimson, and the wing-petals and keel-petals rose-coloured. MR. BEAN states that the plant from which the plate has been prepared is one of the many species bequeathed to Kew by the late Mr. G. C. JOAD in 1881. At Kew the shoots die back to the ground if the plant is grown in the open. Every year, however, slender erect or sub-erect stems, about ½ feet in length, are sent up from the root-stocks, and these flower freely during August and September. It is suggested that if the plants were grown against a wall they would probably survive the winter.

EUCRYPHIA CORDIFOLIA, tab. 8209.—This

species is a native of Chile, and was described and figured in 1797 by CAVANILLE, who was responsible for the genus. The systematic position of the genus has always been doubtful, but Dr. OTTO STAFF, the author of the present description, states that, pending a more comprehensive examination of the genus, it seems expedient to follow C. GAY, who, in 1846, made *Eucryphia* the representative of a new order—Eucryphiaceae. LONDON gives 1878 as the year of introduction of this species into English horticulture, but G. DON has a paragraph containing directions for its cultivation as early as 1831, and Dr. STAFF adds that it remained practically unnoticed until 1897, when it flowered in Messrs. VEITCH'S nursery at Coombe Wood, and a figure of it was published in the *Gardeners' Chronicle* (now reproduced at fig. 52). Mr. BEAN states that the species has never succeeded at Kew, even planted against a sheltered wall. Therefore, unless in the south and west of Ireland, the west of Scotland, Cornwall, and similar localities, the species will need to be cultivated in a temperate house.

RHODODENDRON KAMISCHATICUM, tab. 8210.—Mr. J. HUTCHINSON states that this species is found abundantly in the islands and along the coasts in the neighbourhood of Behring Strait, and that it has been in cultivation for at least 190 years, but, owing probably to the difficulty of its cultivation, it is still comparatively rare. It is an undershrub about 6 inches high, and its branchlets are clothed with long hairs; the leaves are annual, sessile, $\frac{1}{4}$ to $\frac{1}{2}$ inches long, and $\frac{1}{2}$ to 1 inch broad. Flowers are solitary, terminating short branchlets. The corolla is carmine-purple, about $\frac{1}{2}$ of an inch long, and $\frac{1}{2}$ inch broad. Mr. W. J. BEAN states that the species is quite capable of withstanding any degree of winter cold it is likely to experience in the British Isles, but it is deciduous, and, like many other deciduous plants from North Asia, is excited into growth early in the season, being therefore liable to have its young growths injured by late spring frosts. It is a species that requires moisture even more than other *Rhododendrons*. At Kew it has succeeded best when grown in a mixture of peat and silver sand, to which a certain spongy consistency has been given by adding a little chopped sphagnum-moss. It should be given a position where it is sheltered from early morning sun in spring, though otherwise fully exposed, and where the soil is naturally or artificially kept always moist. The illustration at fig. 51 has been prepared from specimens shown by Mr. GEORGE REUBE at the R.H.S. meeting held on June 9 last, when the species was given an Award of Merit.

POLYSTACHYA LAWRENCEANA, tab. 8211.—This species was originally described in the *Gardeners' Chronicle*, August 3, 1893, p. 150, by Dr. KRANZLIN. It was discovered in the Upper Zabehi district by Mr. JOHN BUCHANAN, who sent plants to Mr. JAMES O'BRIEN, and the original description in these pages was prepared from specimens which flowered in the collection of Sir TREVOR LAWRENCE, Bart., at Burford, Dorset. The flowers are yellowish-green, with a rose-pink lip. The present description is by Mr. R. A. ROLFE.

THE ROYAL BOTANIC SOCIETY.—The 69th anniversary meeting of the Royal Botanic Society of London was held on the 10th inst. at the Gardens, Regent's Park, the chair being taken by Mr. C. BRINSLEY MARLAY, vice-president and treasurer of the Society. The reports of the Council and auditors were passed, and the following members of Council re-elected:—Lord BREADALBANE, Lord HOWE, Mr. C. BRINSLEY MARLAY, Sir WILLIAM DENN, Colonel HUTCH FORTESCUE, Mr. H. J. GREENWOOD, Mr. MONTAGU HUTTON, and Captain J. SPARKS. The chairman announced

that the number of new Fellows elected had been greatly in excess of the previous year. The Duke of Teck and Mr. C. BRINSLEY MARLAY were re-elected president and treasurer respectively. Commenting upon the outlook the report says: "There is no section of the Society's work in which there is not every indication of a period of approaching prosperity. The Society is happy in having a united Council. The friction arising from inequality of privileges and differences as to the amount of subscription is being done away. The amended regulations as to the use of the Gardens by Fellows and their friends have met with unqualified approval. In 1907 only 42 new Fellows were elected. Up to July, 1908, 60 Fellows and members had been proposed for election. Almost as many visitors had visited the Gardens up to July, 1908, as visited them in the whole year 1907; and from all quarters the opinion has reached the Council that the Gardens were never more beautiful or better kept than they are at present."

ANGLESEY INDUSTRY ASSOCIATION.—We learn from the *North Wales Chronicle* that a meeting of the executive council of this association was held at Llangefni on the 31st ult. Mr. ROBERT SYDENHAM, of Birmingham, attended by request and addressed the members on the possibilities of cultivating bulbs for commercial purposes in Anglesey. He said that first of all they should satisfy themselves as to the suitability of the soil. He gave instances of the success of the industry in many parts of England, but said that British cultivators could not successfully compete with Holland in regard to the cheaper varieties. A number of specimens were submitted for Mr. SYDENHAM'S inspection by Lady BOSTON and others, and he also examined samples of the local soil. The latter he pronounced to be excellent, and the bulbs well developed. Colonel COTTON made a detailed statement respecting his experiments in bulb growing on a small plantation. Sir RICHARD WILLIAM BYRKELEY, Bart., said he was astonished to hear from Mr. SYDENHAM that the profit on the cultivation of bulbs in some instances was 200 per cent. The great difficulty in Anglesey would be in respect to distribution and collection. He would like to know whether the profit from the sale of bulbs alone would compensate the owner for the cost of cultivation. An industry for the sale of the flowers would be surrounded with difficulties in Anglesey because of the distances to the chief markets. Mr. SYDENHAM stated that in Holland cultivators made fortunes out of bulbs, but they did not sell flowers. It was resolved that a report of the experiments made, and of the opinions expressed by Mr. SYDENHAM, should be included in the annual report. The council then considered the question of school gardening and other subjects.

ALBERT GALLOWAY.—The death of Mr. ALBERT GALLOWAY is announced in the American papers. He was one of the best known Carnation growers in the vicinity of San Francisco. A native of England, he had resided in California for the last ten years. Mr. GALLOWAY was 40 years of age and had no family. He died at his home at Fruitvale, Cal., on July 12.

M. EUGENE DRAPS, the eldest son of M. DRAPS-DOM, the well-known Brussels nurseryman, who excellently cultivated stove and greenhouse plants are usually so greatly admired at the Ghent Exhibitions, has commenced business on his own account as a nurseryman at 30, Chaussée de Forest, Brussels.

DR. HERMANN KARSTEN, formerly Professor of Botany at the Berlin University, died on July 13 at the age of 91 years.

MR. ARTHUR CALDERBANK has been appointed instructor of horticulture at the Agricultural College, Holmes Chapel. For some years Mr. CALDERBANK has been gardener to Mr. W. J. CROSSLEY, M.P. Mr. CALDERBANK is chairman of the Altrincham Gardeners' Improvement Society, and holds a seat on the Hale District Council.

SALE OF FUCHSIAS.—The large plants of Fuchsias in the Zoological Gardens at Clifton, near Bristol, have lately been disposed of by auction, as, owing to requirements of space, room could not be provided for them. Some of the specimens were more than twenty years old, and included the varieties Rose of Castile, Dr. Shaw, Murenka, and Gustave Doré.

RETARDING PLANTS.—It is announced that M. PHILLIPE DE VILMORIN will give an address on "The Retardation of Flowering Plants and the Preservation of Flowers by the Application of Cold" at the international congress of the refrigerating industries to be held in Paris, on October 5-10, 1908.

ROOF GARDENING IN NEW YORK.—New York quick to adapt itself to altered conditions, has become a city of layers, says the *Gardeners' Chronicle of America*. At the bottom is the subway, then come the cellars, above these the ground-floor stores, then the offices, the flats, the restaurants, and on the roof the gardens. Health faddists sleep upon the roof, children play upon them, and women have their afternoon tea and lounge upon them. Gardening on the roof is becoming an art, at which not only gardeners but amateurs are expert. In past seasons but few plants survived the bright sunshine for longer than a fortnight; but now, by carefully choosing the exposure, providing hedges in boxes, and other kinds of screens, flowering plants and vegetables are made to grow on the roofs. Roof gardens no longer consist of an India-rubber plant and a rocking chair. They are luxuriously furnished and screened from the sun by gay canopies and awnings. Instead of being made of tin, which intensified the sun's glare, the roof is either tiled or thickly strewn with sand or pebbles. Just off Stuyvesant Square a man is raising all the vegetables he requires, including his summer Corn (Maize), Lettuces, Carrots, Spinach, Onions, and Parsley, in deep boxes placed on a roof. An apartment hotel in Fifty-fourth Street possesses a roof made attractive with boxes filled with scarlet Pelargoniums around the high sides. On the south side a very high wall is covered with Ampelopsis. A good plant for a hedge on a roof is found in Paris, when planted in deep boxes. Other species of plants, besides Pelargoniums, that, with due care in screening from the sun's rays in hot weather, can be made to furnish plenty of bloom for a length of time, are Petunias, Sweet Alyssum, Aloysia citriodora, Lobelia erinus, Musk, Coleus in variety, dwarf Nasturtium, Heliotrope, Auricula, and Lavender. Doubtless many more will be found to do well as time goes on. The wind is as trying for roof plants as sunshine, and it has to be guarded against. In the hot month of August flowers incline to get scarce in the States, and it is especially so in New York City, and more foliage plants should be planted to take their places when the flowering season has passed. We remember to have observed in a much-exposed situation in Lord ARMSTRONG'S garden at Cragside, Northumberland, quadrangles formed of glazed walls, without roofs, within whose shelter plants both tender and hardy grew very satisfactorily, unhurt by wind or sunshine. If our memory serves us rightly, these walls were 10-12 feet in height, and consisted of iron framework glazed with large panes of glass.

MONS. FRED BURVENICH.—On July 25 a large number of Belgian horticulturists and pupils and friends of M. F. BURVENICH assembled in the Casino at Ghent, in order to present him with a testimonial on the occasion of his golden jubilee as State lecturer and principal teacher of arboriculture and vegetable culture at the Ghent School of Horticulture. M. COLLUMBIEN, speaking in the name of the organising committee, warmly congratulated M. BURVENICH on the celebration of his golden jubilee, laying great stress on the services rendered by him to arboriculture and vegetable culture during the half-century of his professorship. Gardeners had received invaluable aid from his numerous works containing theoretical and practical instruction. There was no one in Ghent who, during a period extending over 50 years, had given such instructive lectures. The speaker referred to the many useful works for which M. BURVENICH was responsible. M. COLLUMBIEN concluded his speech by offering to M. BURVENICH a bust of himself in bronze, a life-like work, by M. GEORGE MINNE, at the same time handing him an address on which were appended the signatures of all the subscribers. M. BURVENICH expressed his thanks to all those who had taken part in the presentation. M. BRAFFORT conveyed to M. BURVENICH the congratulations of the Department of Agriculture. The proceedings were followed by a luncheon at 2 o'clock, at which M. BRAFFORT presided. Many telegrams of congratulation were read, and the president of the committee, on rising to propose the toast of "THE KING," announced that H.M. LEOPOLD II. had nominated M. FRED BURVENICH "Chevalier de l'Ordre de la Couronne du Congo." M. ARTHUR DE SMET, in the name of the Chambre Syndicale, offered M. BURVENICH a magnificent gold medal in recognition of the great services rendered by him to horticulture, whereon M. BURVENICH spoke of the merits of the Chambre Syndicale, which, he said, had contributed in a great measure to the development of horticulture in Belgium.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, ante, pp 84-90)

(Continued from page 106.)

4. MIDLAND COUNTIES.

BEDFORDSHIRE.—Apples are not so plentiful as the quantity of blossom promised; indeed, some varieties are bearing no fruits, but others have over an average crop of very good quality. Pears on walls are bearing good clean fruits; but pyramid trees are bare of a crop. Plums on walls are an average quantity and good. Apricots are scarce, and Cherries are very few. Bush fruits in this district vary. Raspberries are plentiful and good, Gooseberries an average quantity, but Black and Red Currants are below an average crop. Strawberries have been very plentiful and good. Our soil is a heavy loam overlying clay. F. J. Foster, Cranfield Court Gardens, Woburn Sands.

—Notwithstanding the unfavourable weather experienced during the past spring, and especially on April 23 and 24, when fruit trees and bushes were covered with 8 inches of snow, we have every reason to be satisfied with the fruit crop in this district on the whole. Strawberries have been an exceptionally good crop, but Black Currants are below an average one in quantity. George Mackinlay, Wrest Park Gardens, Ampthill.

BUCKINGHAMSHIRE.—The fruit crops in orchards about this district are very light indeed, for few of the trees produced much blossom, and many none at all. The trees are clean and healthy, and very promising for 1909. W. Hedley Warren, Aston Clinton Gardens, Ting.

—The spring of 1908 was full of promise for a full crop of hardy fruits of all kinds. Cold winds and frost at night-time during the month of March kept the flower-beds backward, and all was well until the disastrous snowstorm on the night of April 24, which spoiled the Apple and Pear crops. Gooseberries were in flower at the time and the embryo fruits were ruined. Pear and Apple buds were chilled, and on standard trees in the open orchard they failed to expand and dropped off. Our best crops are on pyramid trees. Grenadier, Bramley's Seedling, and Lane's Prince Albert Apples are all very good. Chas. Parr, Droghere Gardens, Maidenhead.

DERBYSHIRE.—The Apple crop is a very irregular one. Most trees of the Codlin type, together with Devonshire Quarrenden, Lane's Prince Albert, Cellini Pippin, Dumelow's Seedling, and a few other varieties are heavily cropped, while other varieties have scarcely a fruit. Plums and Damsons are almost a failure, and the few that succeed are irregular in common with Apples, are an irregular crop, but on the whole, they are not much under an average quantity. Continuous rains spoiled the last fruits of a heavy crop of Strawberries, but they did much good to all other fruits, as the previous drought had begun to tell severely on all crops. J. C. Tallack, Shipley Hall Gardens, Derby.

—In this district the crops may be described as good. The weather in late spring was favourable for the trees when they were in bloom, the orchards then presenting a pleasing picture, especially the Apple trees, which are now well loaded with fruits, which promise to be of good size and best quality. Gooseberries and Currants escaped the late spring frosts, and are good crops. The Loganberry is being extensively planted everywhere; the strong soil here favours its rapid growth. I have plants of it in my garden planted 18 months ago that have made growths this season 8 and 9 feet long, and they promise to be double that length before they finish growing. Bailly Waddes, 181, Uttoveter New Road, Derby.

—We experienced an exceptionally good May, the month being quite free from east winds and severe frosts; as a consequence, the foliage of the trees is very healthy. The fruit crops generally in this district are much above the average both in quantity and quality. F. G. Mills, Lancside Home Farm, Glossop.

HERTFORDSHIRE.—Some of the fruit crops in this district are much under the average in quantity, especially Apples and Pears, but the few fruits of these are of excellent quality. Plum, Peach, and Nectarine trees are all carrying good crops. Most of the small fruits are good, especially Raspberries, Gooseberries, and Currants; some of the bushes are breaking with the weight of the fruit. In some places Strawberries have been a poor crop, but here the early varieties have furnished excellent fruit; whilst the late varieties are suffering from the excessive rains, and many of the berries are decaying on the plants. Givon's Late Profuse Strawberry without a doubt is better than Fillbasket or Late of All, and the fruits are large and handsome, with a good flavour. C. E. Martin, The Hoe Gardens, Welwyn.

—Although Apples promised an exceptionally good crop, they are not plentiful, owing to many falling when very young. The fruits, however, are very clean, this being especially noticeable in the case of trees that were sprayed thoroughly last winter. We have a light crop of Pears, probably due to the combined effects of last year's heavy crop and the unfavourable autumn weather for ripening the wood. Peaches and Nectarines are a fair crop; Cherries very good; Strawberries, without exception, have been a splendid crop. Of small fruits, Raspberries are heavily cropped with fine fruits. H. Prim, Hatfield House Gardens, Hatfield.

—The shoots made by hardy fruit trees last season were insufficiently ripened, and this is one of the chief causes of scant crops. The heavy snowfall last April minimised the effect of frost upon the blossom to a great extent. F. W. Gooch, The Gardens, Edge Grove, Watford.

—Apple are looking remarkably well, and of this fruit there are good crops of most varieties, and the trees are very clean. Pears are

thin, but Cherries of all kinds are extra good. Bush fruits are all good, and Strawberries were never a better crop, the variety British Queen being very fine and of excellent quality. Edwin Beckett, Aldenham House Gardens, Elstree.

—We have a heavy crop of Apples here, but Pears are much under the average. The same remark applies to Apricots, which, in common with Pears, suffered from late frost when the trees were in bloom. Carter's Profuse Raspberry is bearing a heavy crop, also the Loganberry. The crops of Strawberries have been very good, including the varieties Royal Sovereign, Fillbasket, Gunton Park, Leader, Givon's Late Profuse, and Waterloo. Hy. Parr, Trent Park Gardens, New Barnet.

—Apple and Pear trees flowered well, but did not set their fruits, and this remark also applies to Peaches and Cherries. The weather at the time of flowering was favourable, but the temperature of the soil must have been lowered considerably by the melted snow after the great snowstorm, and this circumstance probably caused the fruit to set badly. Plums do not appear to have been injured. C. R. Fielder, North Myms Park Gardens, Hatfield.

—The fruit crops in this district are generally well up to the average. Apples are a good crop, but Pears are somewhat scarce. All small fruits are abundant, and the bushes are very clean. Of Nuts there are scarcely any, with the exception of Walnuts, of which we have a fair crop. William Poole, Hadham Hall Gardens, Ware.

LEICESTERSHIRE.—The anticipation early in the season of an abundance of all fruits has not been realised. Apples are perhaps the best crop, the most reliable kinds being Newton Wonder, Lane's Prince Albert, Northern Greening, Bramley's Seedling, Stirling Castle, Belle de l'ontoise, Lord Grosvenor, and Seaton House. Plum trees are only partially cropped on walls. Apricot trees did not flower owing, no doubt, to a lack of sunshine in 1907. Gooseberries and Black Currants are failures. Red Currants are small and scarce; they were much damaged by frosts in April. Raspberries and Strawberries have given a full crop of good fruits. D. Roberts, Prestwold Gardens, Longborough.

—The very profuse flowering of Apples has not been followed by such a heavy crop as was expected. Dry, bright weather at the time of flowering was very favourable to caterpillars, and much of the blossom fell early. Cherries also suffered from caterpillars, which is quite an unusual circumstance. Gooseberries fell off, owing to frost, before the flowers opened. Raspberries have done well, and Strawberries are a very heavy crop. Maxton's The Latest, Dr. Hogg, The Countess, Royal Sovereign, and Waterloo being the best varieties the season. W. H. Davis, Belvoir Castle Gardens, Grantham.

NORTHAMPTONSHIRE.—The fruit crops here are generally under an average quantity. We have no Gooseberries owing to late frosts. Red Currants are scarce, whilst Black Currants are about half a crop. Early Apples, such as varieties of the Codlin type, are plentiful, but late Apples are scarce. Pears are a medium crop, and many of these fruits are much damaged by cold winds and the Pear maggot. Silas Cole, Althorp Park Gardens, Northampton.

—Strawberries have been the heaviest crop I have ever had. Lane's Prince Albert Apple is always satisfactory in these gardens, and this year the trees are carrying a heavy crop. Apricots and Gooseberries are almost failures. W. Batchelor, Stoke Bruerne Park Gardens, Towcester.

—The fruit crops in general are very inferior to those of ordinary seasons. There was, however, a fine show for all fruits, but owing to late snow, followed by blight, in the case of Apples and Pears, they are failures. Late frosts ruined the Walnut crop. Thos. Masters, Lower Shuckburgh, Daventry.

NOTTINGHAMSHIRE.—In the spring there was a great promise of abundant crops of Peaches, Nectarines, and Apricots, but on the morning of April 24, 8° of frost were registered, which completely destroyed the prospect. All small fruits are splendid crops. Strawberries are the best I have known for many years. Apples are also good, but Pears are not more than an average number. White Heart and Black

Tartarian Cherries are good, and Morellos promise well. The foliage of all trees is vigorous and very clean. *James B. Allen, Osberton Gardens, Worksop.*

OXFORDSHIRE.—Strawberries have been an extra good crop, and the berries of the best quality. This remark also applies to Raspberries and Black and Red Currants. Gooseberries dropped freely after setting, but the fruits that remain are of good quality. Cherries have also dropped in quantity. Peaches and Nectarines were never better. Although many Apples have fallen, there are plenty left. Pears set very well, and, although many are cracking, they are otherwise good in quality. *A. W. Perry, Middleton Park Gardens, Bicester.*

—Generally the fruit crop in these gardens is a good one. The trees are maintained in a healthy fruiting condition by a periodical examing of the roots for the purpose of keeping them as near to the surface of the soil as possible, and thereby preventing them entering the chalk strata. Pears on walls are a good clean crop, also Morello Cherries. Some varieties of Plums cropped heavily. Apricots are scarce, but there is a good crop of Peaches. Apple trees on the Paradise stock are carrying heavy crops of fruit, which have necessitated much thinning; on old standard trees the fruits are small. Seldom before have Strawberries proved so good and plentiful in this district, Giron's Late Prolific suiting our soil. Raspberries are abundant, and Gooseberries of some kinds are full crops. Black Currants bear particularly fine fruit in this neighbourhood, and they are plentiful. *W. H. Clarke, Aston Rowant Gardens, Wallingford.*

—Apricots last year were so heavily cropped that our trees did not flower this season. There was also no blossom on many trees of Apple, Plum, and Pear. After such a cold summer as last year one could scarcely expect fruit buds to form. The foliage of Cherry and Apple trees has been much disfigured by caterpillars. *A. J. Long, Wyfold Court Gardens, South Oxford.*

—The fruit season of 1908 will be remembered for an almost complete failure of the Gooseberry crop. Raspberries are plentiful and of good quality. Currants of sorts are by no means so plentiful as is usual in these gardens. *J. Broadfoot, Shotover Gardens, Wheatley.*

SHROPSHIRE.—Owing to severe frosts in May the early flowering Apples are a thin crop, but the later flowering varieties, such as Jubilee, are plentiful. Most of the trees on the Paradise stock are bearing a heavy crop of good clean fruits. The same remark applies to Pears and Plums; on sheltered trees and late flowering varieties there are sufficient fruits. Apricots and Peaches suffered greatly from the frosts of May, and are very scarce. Strawberries are a splendid crop, in fact, the best for years past. Other small fruits are an average crop only, Gooseberries, especially, being very few. *A. Daggart, Moor Park Gardens, Ludlow.*

—From the soft, unripened condition of the wood at pruning time, I expected poor returns from the fruit trees this season, and this is the case. The Apple crop is very thin, even in the case of free-cropping varieties. Pears on south and west walls, and on pyramid and bush trees are a poor crop. Plums are a medium crop; but Cherries are good. Peaches and Nectarines are much below an average quantity. Figs on wall trees are satisfactory. Amongst bush fruits, Gooseberries, Raspberries, and Red Currants are excellent. Strawberries have been abundant and of good quality. All our fruit trees were sprayed during the winter, and are now clean and healthy. Our soil is of a close, tenacious character, resting on a clayey subsoil. *Chas. Roberts, Halston Gardens, Oswestry.*

—Fruit trees of all kinds appear remarkably healthy, and are making good growths, Peach trees in particular. The bloom on trees was irregular and not at all general; then, on April 25, frost ruined the Peach and Pear bloom, although protected, and Potato haulm 3 inches high close under the wall was cut down. I did not consider the individual blooms at all strong, whi h was not to be wondered at after the cold, wet summer of the previous year. However, things promise well for another year if the autumn is favourable. *John Taylor, Hardwick Grange Gardens, near Shrewsbury.*

STAFFORDSHIRE.—There was an abundance of blossom on all kinds of hardy fruit trees. Apples, Cherries, and Strawberries all set grand crops; the fruits of the latter were not only produced in quantity, but were also of good quality. Pears are thin but good in quality. Bush fruits promised well, but the heavy fall of snow experienced just at the time the fruits were

situated lies low, and therefore we suffer greatly from late frosts, which this year destroyed many Gooseberries. Currants are an excellent crop. Some varieties of Apples, such as Bess Pool, Lane's Prince Albert, Golden King, Cox's Pomona, and Worcester Pearmain, are well fruited. *A. Cheney, Shenstone Court Gardens, Lichfield.*

FIG. 53.—STURTIA MALACHODENDRON, AN ORNAMENTAL DECIDUOUS SHRUB: FLOWERS WHITE.

setting reduced the crop very much, especially in the case of Black Currants and Gooseberries. *Geo. Woodgate, Kelliston Hall Gardens, Burton-on-Trent.*

—The district in which these gardens are

situated lies low, and therefore we suffer greatly from late frosts, which this year destroyed many Gooseberries. Currants are an excellent crop. Some varieties of Apples, such as Bess Pool, Lane's Prince Albert, Golden King, Cox's Pomona, and Worcester Pearmain, are well fruited. *A. Cheney, Shenstone Court Gardens, Lichfield.*

(Photograph by E. J. Wallis.)

do not amount to even a moderate crop, and the same may be said of Pears. Apples have fared better, but the set of fruit upon many of the trees has fallen far short of what was expected at the time of flowering. Some trees are heavily laden, some have few fruits, and others none, and this appears to be general around this neighbourhood. Cherries seem to have fared better, and especially Morellos, which are very promising. Strawberries were plentiful, and they rank as the best fruit crop of the year. Black and Red Currants and Raspberries have given fairly good returns, and, judging from what I can see in my own place, I think the Loganberry has come to stay, although I am not quite satisfied with the flavour of the fruit. In this opinion birds seem to agree, as they do not appear to eat them whilst there are other fruits about. There is a small Apple orchard at Bars-ton Hall near here, the country residence of J. Roderick, Esq. There are many varieties of Apples in this orchard, and amongst them is a long avenue of Bramley's Seedling. They are standard trees, with fully-developed heads all around, reaching down to the ground, and they are now heavily laden with fine promising fruit. With the exception of a little thinning occasionally of internal shoots, these trees are allowed to grow quite naturally. Such is their superior condition of culture, that I question if a much better lot of fruited trees could be found in any of the oversea fruit-growing districts of the world. At Barston Hall there are 4½ acres of fully-grown Walnut trees; these, too, are heavily laden with clusters of fine healthy fruit, having from three to nine nuts in each cluster. W. Miller, Berkswell.

(To be continued.)

STUARTIA MALACHODENDRON.

This ornamental shrub is a native of North America, and has been known as *S. virginica*, being found in Virginia as well as in others of the United States. It is a showy-flowered species, and forms a fine ornamental shrub for gardens; in favoured spots in this country it will grow to a height of from 6 to 12 feet. The leaves are oval in shape, being acute at both ends; they are light green in colour and pubescent beneath. The flowering season in this country is July and August, but in its native habitat it flowers during May and June. The stamens are purple and spreading, which distinguish this species from others.

In planting, a moist situation should be selected, for the roots must never be allowed to become dry, and the soil should have incorporated with it a considerable quantity of peat. The site should be a sheltered one, for the shrub is likely to suffer if exposed to cold winds, and more so than from low temperatures. The species was illustrated, from a sketch, in these pages October 6, 1877, p. 433, our present illustration at fig. 53 being from a photograph by Mr. Wallis.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

MITES ON POT PLANTS.—When pot plants are found to be in an unsatisfactory condition of growth, under normal cultural conditions, and the presence of mite or other insect pests is suspected, either dipping or spraying with some approved insecticide should be practised. This is best done in the evening, as the specific will so readily evaporate from the foliage as to be in the day-time. I have found the XL-All liquid insecticide the most efficacious, but clear soft water is also effectual if frequently used, and in some cases better than any other preparation. Quassa extract I have also proved to be very good. A small winglessful of XL-All liquid to two gallons of water is a safe and effectual quantity for use. Where plants have been infested with mites, causing their growth to be unhealthy and stunted, I have noticed a marked improvement in a few days after using one or other of the above preparations. On the wall trees of Plum and Morello Cherry, I have found the foliage early in the year to be attacked with a minute insect which has turned the leaves a

silvery tint, almost like a slight attack of the silver-leaf disease. My remedy in that case has been to syringe the foliage in the evening with a solution of soft soap and washing soda, using 4 lb. of soft soap and 2 lb. of soda dissolved in three gallons of boiling water; a quart of this solution to two gallons of water is a safe and effectual cure. F. Street, The Gardens, Ardwell, Wigtonshire, N.B.

THE WAR ON RATS.—In order to obtain accurate information regarding the nature and extent of the damage done by rats within the United Kingdom, my committee has prepared a schedule of questions which they desire to place into the hands of all those who are in a position, from their own experience, to give valuable information concerning temporary or permanent rat plagues in their districts, the damage inflicted by rats, the steps taken by them—individually or in co-operation with others—for preventing such damage, the means chosen for that purpose, and the results obtained. As the only means of gathering important knowledge of that kind is by favour of the Press—short of undertaking the appalling task of sending the questions to every one likely to suffer, or to have suffered, loss through rats, that is, to every household in the country—my committee venture to hope that you will permit an appeal to your readers to support the society by asking for a copy of the schedule and returning it with such information as they may be able to impart. A. E. Moore, Secretary, Society for the Destruction of Vermin, 95, Wigmore Street, London.

RENANTHERA COCCINEA.—A plant of *Renanthera coccinea* flowering in June in Mrs. L. C. Joad's garden at Patching, Wotthing. It had an inflorescence about 2 feet long and 2 feet wide, bearing 50 flowers fully out. This Orchid I think is rather shy in flowering; it has flowered here five times in 26 years. The plant is 14 feet long, growing on a piece of wood fastened to a rafter in the fernery. I enclose a photograph.—[Unsuitable for reproduction.—Ed.]—Charles Hack, Patching Gardens, W. riving.

ISMENE CALATHINA.—It may not be generally known that this pretty bulbous plant is improved in health by being planted out-of-doors after flowering, where it should remain till frost destroys the leaves. The bulbs should then be lifted and placed under the stage in a warm house and kept dry. By this method of treatment the bulbs increase in size and vigour, and develop two or three flower-spikes. As these develop early, the bulb would, in any case, be greatly injured if it were dried off immediately after flowering. F. M.

GRAFTING THE DOUBLE-FLOWERED VARIETY OF GYPSOPHILA PANICULATA.—As this variety is somewhat difficult to raise from cuttings, growers have had to adopt another method of propagation. This is by grafting, and it is surprising what a large quantity of plants can be secured from one or two stock plants in a short period, provided proper attention is given to the operation. The plant or plants from which the grafts are to be taken should be carefully lifted, potted and placed in a warm temperature, for little success is obtained if the grafts are taken from plants growing in the open, and the roots for stock plants dug up carefully in reserve plants of the species, and cut off all the available pieces of roots. These need not be more than 3 or 4 inches in length, whilst pieces considerably thicker than the grafts can be utilised. When the shoots to be employed as grafts are about 3 inches in length they are ready for working, and can then be grafted on to roots which correspond to them in thickness. If the roots are much thicker than the grafts, it is advisable to notch them in a triangular form about 1 inch long, and the graft should be similarly prepared and made to fit therein. All the newly-grafted portions should be laid in damp moss until it is convenient to pot them, and for this purpose an ordinary compost is suitable. A closed case with a temperature of 60° to 65° is necessary for their accommodation, and into this some such material as coconut fibre or leaf-mould should be introduced for plunging purposes. After the union has taken place the plants should be removed from the case, and in a week or two they will furnish other grafts or scions from their top shoots. W. B. Little, 21, Haverfield Gardens, Kew.

SOCIETIES.

ROYAL HORTICULTURAL

Scientific Committee.

AGUST 4.—*Present:* E. A. Bowles, Esq., M.A., F.L.S. (in the chair); Messrs. Francis, Bennett-Poe, Douglas, Holmes, Masee, de B. Crawshaw, Fraser, Shea, Saunders, and Chittenden (secretary).

“*Black-eye*” of *Carnations*, &c.—Mr. MASSEE, V.M.H., showed flowers of various species of *Dianthus*, including *Carnations*, affected by the fungus *Ustilago violacea*, which develops its spores in the anthers of different species of *Caryophyllaceæ*. The fungus is common to wild plants belonging to the order, but is less common on cultivated plants. The mycelium is perennial in the tissues of its host, and therefore it is useless to attempt a cure; affected plants are best destroyed. The host plants can only be attacked when in the seedling stage or in the young shoots, and nothing can be seen of the fungal attack until the fruiting stage is reached in the anthers of the host. It is then known by the blackish dusty mass of spores in the centre of the flower.

An uncommon fungus.—Mr. HOLMES, F.L.S., showed numerous specimens of the curious saprophytic fungus *Geaster Bryantii*, which had occurred in a dry border recently manured with farmyard manure in his garden at Sevenoaks.

Listrostachys forcipata.—Mr. DOUGLAS, V.M.H., showed a plant of this rare and beautiful little Orchid, bearing several of its curious delicate white flowers, the perianth of which is apparently but one cell in thickness. The plant is a native of dense forests in Buea, Cameroons, at an elevation of 4,200 feet. (See Kranz in *Engl. Jahrb. xix. 254; Flora Trop. Afr. viii.*) A Botanical Certificate was unanimously recommended for this plant.

“*Wheat-ear*” *Lychnis alba*, &c.—Mr. FRASER, F.L.S., showed specimens of this plant, having the bracts usually below the flower repeated again and again, the flowers themselves being almost aborted, the sepals being much lacinated. Similar peculiarities are produced in certain plants through the attacks of *elworm*. Mr. BOWLES, M.A., showed a similar peculiarity in *Dianthus superbus*, the plant bearing the inflorescence having been taken from a plant showing the same peculiarity exhibited by Canon ELLACOMBE last year.

Sweet Peas dying.—Mr. FRASER also showed Sweet Peas with prematurely yellowed foliage. The root had been attacked by the fungus *Thielavia basicola*, a species of which is apparently very common this year.

Salix undulata.—Mr. FRASER also showed two specimens of Willow shoots cut from the same bush at different periods in the year. In April the ovary was completely glabrous; but in August the ovary had become pubescent—a character typical of *S. undulata*.

Variation in plants.—Mr. SHEA made some observations upon this subject, exhibiting variegated leaves of a Sunflower. Last season one side (that towards the magnetic north pole) had shown variegated leaves, the remainder of the foliage being normal. He had saved seeds from that side of the inflorescence, and the seedlings were weaker and bore variegated leaves throughout, while seeds from other parts of the inflorescence produced normal plants. Mr. SHEA said that he had observed in other cases of this variation had been confined entirely to the side of the plant towards the magnetic north pole.

Variation in Delphinium “Carmine Queen”.—From Messrs. VEITCH, Chelsea, came inflorescences of this *Delphinium* showing some flowers of a beautiful violet blue, others of a pinkish tinge, and others again streaked and splashed with both colours. All the flowers of some shoots were of one colour, of others the two colours were restricted to separate flowers, and in others the whole of the flowers were of both colours intermingled. It was noticeable that there were no intermediate shades of colour.

Varieties of Epitaphium hirsutum.—Mr. BOWLES, M.A., showed specimens of the normal form of *E. hirsutum*, with a very hairy form, with deeper flowers, from South Europe, a form with white petals and red stamens, a form with white petals and stamens, the variety, however, showed the usual red tinge, and a virescent form.

Ants and aphides.—The following communication was received from the Rev. H. E. BISHOP, M.A., Middleton Vicarage, King's Lynn:—"Some Gooseberry bushes are trained on a north wall in my garden. During the wet weather I noticed that many shoots were encrusted with sand and lime (somewhat in the manner of the case of a caddis worm), and on breaking this away we were surprised to find the shoot covered with aphides and the ants busy among them. After examination we came to the conclusion that the ants had constructed the cases to prevent the aphides being washed away by the rain. The piece broken away was repaired the next day. The upper leaves seemed to serve as a roof, and the sand built round left a clear passage way round the aphides. Since the settled fine weather the casings have been completely cleared away." Mr. CHITTENDEN observed that he had seen a similar thing in a greenhouse, where the ants constructed a covering over aphides on the stem of a Cineraria.

SCOTTISH HORTICULTURAL.

AUGUST 4.—The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh, on the above date. Mr. Whytock, the president, was chairman, and there was a good attendance of the members. Mr. C. Comfort, Bromfield, Davidson's Mans, read a paper on "Modern Gardening Appliances." The paper was of a very comprehensive nature, bringing within its scope almost every conceivable implement and appliance (of which Mr. Comfort had an excellent exhibit) used by the gardener in the pursuit of his calling.

Some interesting plants were exhibited at the meeting, and the adjudicating committee awarded a First-Class Certificate to a new early-flowering Chrysanthemum named "Rob Roy," raised by Mr. WM. ROBERTSON, Pilrig House Gardens, Leith. Some seedling Carnations, the result of crossing border kinds with "Malmaison" varieties, were shown by Mr. R. VALLANCE, Carden Gardens, Meigle, Perthshire. The interesting point in connection with this cross is that single-flowered varieties rarely appear, whereas when border Carnations are crossed with border varieties the majority of the seedlings are single. Specimens of the "sleepy" disease of Tomato were shown by Miss BURTON, Polton, and Mr. R. CAIRNS, Mureston, Mid-Caldor; the new Sweet Pea "Mrs. Bieberstedt" by Messrs. BELL & BIEBERSTEDT, Leith; Raspberries "Hornet" and "Superlative," by Mr. W. G. PRIBB, Dalhousie Castle Gardens, Midlothian, to show the superiority of the former of the latter in so far as it leaves the "core" more readily when it is pulled; Rambler Rose "Tausendschön," Fhlox "Tapis Blanc," and flowers of white (annual): Asters, with very long stems, from plants sown in the open ground, and not transplanted, by Messrs. TODD & Co., Edinburgh. Mr. LITTLE, Saughton House Gardens, Edinburgh, had an exhibit of Sweet Peas; and Mr. JOHNSTONE, Hay Lodge, Edinburgh, one of Fuchsias.

Three new members were elected. The paper for the next monthly meeting, on September 1st, will be by Mr. Thomas Fender, Clotghuey, Crieff, on "The Pleasures and Penalties of Vegetable Judging, with Suggestions as to Improved Methods of Staging."

ROYAL HORTICULTURAL OF IRELAND.

AUGUST 5.—Associated with the customary annual exhibition of this important Irish association was held the second provincial show of the National Sweet Pea Society. The venue was the Royal University, and to accommodate the various exhibits several rooms had to be requisitioned, with the unfortunate result that the spectacle was poor in comparison with what it would have been had space proved available in

one large hall, but the quality in some of the classes was most creditable. The section devoted to Sweet Peas was extensive, and some magnificent blooms were contributed from various parts of Ireland, but the Edwards' Provincial Trophy was won by an English exhibit from Mr. T. STEVENSON, Woburn Place Gardens, Addlestone, with a superb collection. Practically all the classes were contested with keenness. The arrangements were well carried out by the secretary, Mr. Edward Knowlton. The National Sweet Pea Society was officially represented by its secretary, Mr. Chas. H. Curtis, and Mr. Horace J. Wright.

THE GENERAL EXHIBITION.

Considering the date of the show, the Rose exhibits were good, especially in those classes where Messrs. HUGH DICKSON, Belfast, and ALEX. DICKSON & SONS, LTD., Newtownards, were the contestants. The former firm's set of 72 blooms were bright and fresh. Some of the best examples were Hugh Dickson, Eugene Leach, Elfr. Majesty, Ben Cant, and Bessie Brown. In Messrs. A. DICKSON & SONS' 2nd prize collection Frau Karl Druschki, Mildred Grant, and Mrs. John Laing were notably good. In the class for 12 blooms the positions of the prize-winners were maintained, substantially the same varieties being included. Messrs. A. DICKSON & SONS, LTD., staged alone in the class for 24 blooms of Tea Roses, and received the 1st prize. In the class for a table of Roses arranged for effect, Mr. HUGH DICKSON won the 1st prize, and Messrs. A. DICKSON & SONS the 2nd, both having exhibits of conspicuous beauty. Roses shown by amateurs were fairly numerous, and, in some instances, meritorious. Messrs. W. H. CALVERT, J. S. B. SARNOR, R. J. C. MANSELL, T. F. CROZIER, A. PANTON, and S. S. MILLER, the Hon. Mrs. BARRY, and Dr. O'DONEL BROWNE were prominent prize-winners.

The class for a collection of hardy cut flowers was a splendid one; but Captain LEWIS RIALLI, Bray, and the Rt. Hon. Lord PLUNKET staged excellently. For 12 hardy annuals of distinct kinds, Dr. O'DONEL BROWNE was a good 1st prize-winner with examples showing excellence of culture: the flowers were bright, fresh, and effectively staged. The 2nd prize was won by the Hon. Mrs. BARRY, who also showed well. There were several exhibitors in the class. Asters in vases were attractive, and the blooms shown by Mr. H. J. B. CLEMENTS were beautiful samples. Carnations and Picotees were not so well shown as might have been anticipated, but Mrs. TACKBERRY, and Messrs. A. ARMSBROG and H. CARROLL had good blooms.

For 24 Cactus Dahlias, Mr. R. H. STUBBER was an easy 1st prize-winner with a clean, even set of the leading varieties; 2nd, Mr. C. M. DOYNE. For six varieties of the same flowers, shown in vases, Mr. W. ROSS was awarded the 1st prize.

Cut blooms of double tuberous-rooting Begonias were superbly staged, the 1st prize collection of 36 blooms, shown by Mr. G. C. STABLETON, being almost perfect; Mr. R. H. STUBBER was awarded the 2nd prize. For 12 blooms, Mr. T. F. CROZIER and Mr. R. J. C. MANSELL were 1st and 2nd respectively, and again the blooms were excellent. There were classes for cut blooms of single and double Zonal Pelargoniums, as well as for plants in pots, and in each case Mr. ERNEST BEWLEY showed the premier examples.

Exhibits of fruits and vegetables were shown fairly largely, but, except in the classes for Currants, there was nothing of outstanding merit. Black and White Grapes and other choice fruits helped to render attractive the room in which this section was staged.

SWEET PEAS.

The classes for Sweet Peas were very numerous, and sub-divisions were made for Irish growers, for amateurs only, and for all comers, and in every case the average quality was high, the blooms being fresh, bright, and of good substance, while the number of coarse stems, which very nearly succeeded in making even the Sweet Pea ugly, were few. As has already been said, Mr. T. Stevenson (gr. to E. MOCATTA, Esq., Woburn Place, Addlestone, Surrey) won the handsome Challenge Trophy presented by Mr.

Ernest J. Edwards for competition amongst amateur growers at the provincial exhibitions of the N.S.P.S. Twelve varieties were called for, and the winning set was excellent in every respect. Mr. King (gr. to Lord DUNLEATH) was 2nd, and Mr. J. Reid (gr. to G. T. RICHARDSON, Esq.) 3rd. There were no fewer than nine competitors in this class.

Messrs. A. Dickson & Sons, Ltd., offered a very handsome bowl, open only to Irish growers, for 12 distinct varieties of Sweet Peas. The competitors numbered no fewer than 21, and almost all of them staged strongly. The place of honour was handsomely won by Mr. E. COWDY, Greenhall, Longhall, who had beautiful bunches of Mrs. Harcastle Sykes, Prince of Asturias, John Ingman, Marjorie Willis, Evelyn Hemus, the Marquis, and Yellow Spencer, among others. Mr. King was worthily placed 2nd with Sutton's Queen, King Edward VII., White Spencer, Helen Lewis, St. George, and Queen Alexandra as his best varieties. The 3rd prize went to Miss OSBORNE, Dardistown Castle.

In the class for six bunches, distinct, Mr. Davies (gr. to Mrs. GOODBODY, Obelisk Park, Blackrock) won the 1st prize with the varieties Etta Dyke, Countess Spencer, Helen Lewis, Mrs. Harcastle Sykes, King Edward VII., and Queen Alexandra. The 2nd and 3rd prizes were won by Messrs. H. J. R. DIGGLES, Doneybrook, Dublin, and A. PHIPPS, St. Anne's, Terenure, in the order named. The National Sweet Pea Society's Silver Medal was included in the premier prize in this class.

For three bunches of Sweet Peas, distinct, Messrs. J. HALL, Moy, Co. Tyrone, and F. V. WESTY, Dundrum, were awarded the 1st and 2nd prizes respectively, the winner showing beautiful bunches of Helen Lewis, Countess Spencer, and Dorothy Eckford. With the exception of the Edward's Trophy Class, the preceding were restricted to Irish growers.

Four competitors staged in the Special Audit Class for 15 bunches, distinct. Mr. KING's exhibit being placed 1st, MARK McDONALD'S, Esq., Portlerry, Co. Down, 2nd, and Mr. CASTER's (gr. to Mrs. WEST, Bray) 3rd; the varieties shown were excellent.

MESSRS. H. J. B. CLEMENTS, Celbridge, J. MILNE, Naas, and MITCHISON were the successful exhibitors in a class for 12 bunches, distinct. The last-named exhibitor showed splendidly in a class for six bunches, distinct, the varieties being Helen Lewis, Clara Curtis, Mrs. Henry Bell, Purity, John Ingman, and Mrs. Harcastle Sykes; the 1st prize was worthily awarded this exhibit.

The open classes, apart from those restricted to single bunches, were disappointing, owing to a lack of competition. Mr. C. W. BREADMORE, High Street, Winchester, was the only exhibitor in the Classification Class for 18 bunches, distinct, and he received the 1st prize. Mr. BREADMORE was again successful in the class for 12 bunches of distinct varieties having varied colors, showing George Herbert, Kitty Crier, Etta Dyke, Elsie Flebert, Andrew Grant, Mrs. C. Foster, Primrose Waved, Marjorie Lizzie, and King Alfonso, amongst others.

The single-bunch classes, open to all comers, were keenly contested, and many magnificent bunches were exhibited. The prizes were principally allocated to growers whose names have previously been mentioned.

NON-COMPETITIVE EXHIBITS.

As is customary at exhibitions of this character, the groups of plants and flowers contributed by trade and other growers not for competition added very substantially to the interest and beauty of the display. Among those who staged exhibits of Sweet Peas were Messrs. A. DICKSON & SONS, LTD., Newtownards; Mr. C. W. BREADMORE, Winchester; Mr. R. BOLTON, Carnforth; and Messrs. HOGG & ROBERTSON, Dublin, all of whom staged the finest varieties in meritorious condition. Messrs. J. CARTER & Co., High Holborn, arranged a varied group, comprising excellent flowers and vegetables; Messrs. W. DRUMMOND & SONS, Dublin, staged particularly hardy flowers in a handsome group; Messrs. A. DICKSON & SONS, LTD., contributed beautiful examples of Fhloes, Pentstemons, Pyrethrums, and many other hardy plants; Messrs. W. WATSON & SON, Dublin, sent *Kochia scoparia*,

Asparagus Sprengeri, Roses, Sweet Peas, and Carnations; while Messrs. HOGG & ROBERTSON, Dublin, arranged a magnificent collection of Gladioli. Messrs. W. RAMSEY & SON, Ballsbridge, staged excellent Begonias, Roses, Liliums, Sweet Peas, Palms, and Crantons; Mr. W. Usher (gr. to Mrs. KEITH, Brennanstown, Cabinteely) showed beautiful Tydeas, (Caladiums, and Palms.

MIDLAND CARNATION AND PICOTEÉ.

AUGUST 6, 7.—The 18th annual exhibition was held as usual in the Botanical Gardens, Edgbaston, Birmingham. Owing to the very trying season there was a great falling-off in the number of entries in all the classes except those reserved for amateurs. The impression one gained of the Carnation flowers generally was that, in addition to being shown in smaller numbers than in some previous years, the quality was below the Birmingham standard. (One exhibitor—Mr. W. H. PARTON—secured eight 1st and two 2nd prizes out of ten entries in the section devoted to undressed flowers.

Sweet Peas were well shown, and to a certain extent made up for the weakness of the Carnations. The non-competitive group of Roses and hardy herbaceous flowers from the nurseries of Messrs. GUNN & SONS, of Olton, will be long remembered as one of the firm's best efforts at Edgbaston. The Gold Medal awarded was richly deserved.

DRESSED FLOWERS ON STANDS.

Self Carnations.—Only four exhibits were staged in this, the leading, class for 12 self Carnations. The 1st prize was won by Mr. C. F. THURSTAN, Penn Fields, Wolverhampton, who showed splendid flowers of Daffodil, Carabas, Ed. Kenyon, W. H. Parton, Mrs. Flight, Sir Galahad, Miss Willmott, Mrs. Eric Hambro, Sir Bevis, Pink Pearl, Ensign, and Mrs. L. E. Best. 2nd, Mr. A. R. BROWN, King's Norton, whose best flowers were Daffodil, W. H. Parton, Cecilia, and Milton.

In a smaller class for six self Carnations, the Rev. C. A. GOTTWALTZ, Hadzor Presbytery, Droitwich, beat seven competitors. The varieties consisted of John Pope, Daffodil, Helen Gottwaltz, Hadzor, Major Galton, and Miranda. 2nd, Mr. F. W. GOODFELLOW, Walsall.

Twelve yellow-ground Picotees.—The leading award in this class went to Mr. A. W. JONES, Stechford, who put up a splendid stand of the following varieties: Lady Gascoigne, Agnes, Sunbeam, Ida, Goblin, Lady Halford, Astrophel, Sophie Western, Leonora, Penelope, Lucy Galton, and J. Brocklehurst. Mr. C. F. THURSTAN, who was placed 2nd, had smaller flowers of very good quality.

The Rev. C. A. GOTTWALTZ just managed to beat Mr. F. W. GOODFELLOW in the smaller class for six yellow-ground Picotees. Each exhibitor showed superb blooms.

Twelve fancy Carnations.—Mr. A. W. JONES took the lead in this class, having superior blooms of the following varieties, viz.: Lord Steyne, Billy Barlow, Sam Weller, Erl King, Queen Bess, Mandarin, Professor Cooper, Liberté, Babastes, Lara, R. A. Rowberry, and Highland Lass. 2nd, Mr. A. R. BROWN.

In a class for six fancy Carnations there was very little to choose between the Rev. C. A. GOTTWALTZ and Mr. HARRY SKELLS, Walsall, who were placed 1st and 2nd respectively. The flowers in each stand were beautifully fresh and of considerable bloom.

Twelve white-ground Picotees.—Mr. A. R. BROWN took the lead with shapely flowers of Maud Brown, W. E. Dickson, Fair Maiden, Mrs. Chaundy, Lavinia Fontrose, Britteette, Miss Evelyn Cartwright, Duchess of York, Linda, Lady Sybil, and Polly Brazil. 2nd, Mr. C. F. THURSTAN.

Twelve flukes or bisarres.—Mr. C. H. HERBERT was 1st with a good set for twelve flowers, and for six blooms Mr. W. DERRY, Edgbaston, was 1st with a nice lot of flowers except Sportsman, which was past its best.

SINGLE BLOOMS.

Twenty-six classes were devoted to these, but competition was poor in most of them, there being only just a few more than half the number of the flowers staged in 1907. The most successful exhibitors were Mr. A. R. BROWN, Mr. C. H.

HERBERT, Mr. C. F. THURSTAN, and the Rev. C. A. GOTTWALTZ.

UNDRESSED FLOWERS.

Twelve self Carnations.—The five exhibits in this class made a good display and afforded a relief to those shown in boxes. They were staged in the usual way of three from front to back in a space not exceeding 24 inches by 20 inches. No wire was allowed except a mere support not to come beyond the base of the calyx. Tier staging was employed and vases of uniform size provided. Mr. W. H. PARTON, Hollywood, secured 1st prize with excellent flowers of Mrs. Guy Sebright, Daffodil, W. H. Parton, Bridegroom, Sappho, Mrs. F. W. Flight, Cassandra, Britannia, Denbow, Much-the-Miller, Miss Willmott, and Sir Bevis. 2nd, Mr. C. H. HERBERT, whose best flowers were W. H. Parton, Daffodil, and Conrad.

For six self Carnations, Mr. C. J. WHITE, Walsall, beat six competitors. With the exception of John Pope all the blooms in this stand were good. 2nd, Rev. C. A. GOTTWALTZ, with smaller flowers, Ethel Brown being the weakest in the set.

Twelve fancies or yellow-grounds.—Mr. W. H. PARTON won 1st prize with a handsome lot of flowers. His best examples were Voltaire, Cavalier, Lord Steyne, Liberté, and Merlin. 2nd, Mr. A. R. BROWN.

For six fancies or yellow-grounds, the Rev. C. A. GOTTWALTZ and Mr. HARRY SKELLS were placed in the order named.

FLOWERS SHOWN IN THREES.

Twelve selfs, yellow-ground Picotees or fancies.—The flowers which gained 1st prize for Mr. W. H. PARTON was one of the finest set of trebles ever staged at Birmingham. They were large without showing the slightest tendency to coarseness, beautifully fresh and well set up. The varieties were as follows: Voltaire, Gallico, Liberté, R. A. Rowberry, Lord Steyne, Merlin, Conny, Buchanan, Lucifer, Sappho, Sam Weller, Daffodil, and King Solomon. 2nd, Mr. A. R. BROWN, whose best flowers were Lord Steyne, II. J. Cutbush, and Margaret Thurstan. 3rd, Mr. A. W. JONES.

In a similar but smaller class for six flowers Mr. G. D. FORD won the 1st prize.

SINGLE VASE CLASSES.

Six classes were provided for these, but competition was disappointing in some of them. The most successful exhibitor was Mr. W. H. PARTON, who secured four 1st prizes for (1) white, with Hildegarde; (2) rose, salmon, or scarlet, with Bridegroom; (3) yellow, with Daffodil; and (4) dark Carnation, with W. H. Parton.

Mr. A. R. BROWN won the 1st prize in the class for yellow-ground Picotees with Lucy Galton, and in that for a yellow or buff-ground fancy variety, with Lord Steyne.

AMATEUR CLASSES.

Competition in the five classes reserved for amateurs who do not grow more than 300 plants was very keen, there being no fewer than 15 exhibits in one class and 13 in another.

Mr. J. D. WILLIAMS, Smethwick, won 1st prizes in the classes for (1) six white-ground Carnations or Picotees, dressed; (2) six fancy or yellow-ground Carnations or Picotees, dressed and six fancy or yellow-ground Carnations or Picotees, undressed.

Mr. S. FORD, Tulseley, and Mr. J. T. SMISTER, Denstone, Uttoxeter, secured the 1st prizes in the two remaining classes.

AWARDS.

First-Class Certificates were awarded to:—*Carnation Mrs. C. H. Herbert*, a light purple-edged Picotee, from Mr. C. H. HERBERT, Acocks Green; *C. Lady Gascoigne*, a light rose-edged Picotee, from Mr. A. W. JONES, Stechford.

PREMIER FLOWERS (DRESSED).

Bizarre Carnation Admiral Curzon, shown by Mr. C. H. HERBERT; *Flake Carnation Gordon Lewis*, shown by Mr. C. F. THURSTON; *heavily-edged, white-ground Picotee Mrs. W. H. Twist*, shown by Mr. F. W. GOODFELLOW; *light or wire-edged, white-ground Picotee Mrs. C. H. Herbert*, shown by Mr. C. H. HERBERT; *heavily-edged, yellow-ground Picotee Togo*, shown by Mr. HAYWARD MATHEAS; *light-edged, yellow-*

ground Picotee Mrs. Brocklehurst, shown by Mr. A. W. JONES; *yellow-ground fancy Carnation Earl King*, shown by Mr. A. W. JONES; *self Carnation Daffodil*, shown by Mr. C. H. HERBERT.

PREMIER FLOWERS (UNDRESSED).

Self Carnation W. H. Parton, shown by Mr. W. H. PARTON; *fancy Carnation Lord Steyne*, shown by Mr. A. R. BROWN; *yellow-ground Picotee Mrs. W. Heron*, shown by Mr. C. H. HERBERT.

SPECIAL MEDALS AND PRIZES.

The Birmingham Botanical and Horticultural Society offered two medals to the exhibitors gaining the greatest number of points in the large classes, and two medals to the most successful exhibitors in the smaller classes.

The Silver Champion Medal was won by Mr. A. R. BROWN with 132 points, and the Bronze Medal by Mr. C. F. THURSTAN with 107 points. The Rev. C. A. GOTTWALTZ won the Silver Medal in the small classes with 100 points, the Bronze Medal being awarded to Mr. F. W. GOODFELLOW with 53 points.

The Carnation Society's Silver Medal, offered to the most successful exhibitor in the single bloom classes (dressed flowers) and the single vase classes (undressed flowers) was won by Mr. A. R. BROWN.

The Bronze Medal, to the most successful exhibitor in the amateur classes, was awarded to Mr. J. D. WILLIAMS.

SWEET PEAS.

Special prizes were offered by Mr. Robert Sydenham for 18 varieties. Eight good exhibits were staged. The 1st prize was won by Mr. T. JONES, Raubon, with a handsome lot of long-stemmed flowers; 2nd, Mr. J. HAYCOCK, Wrexham; 3rd, Mr. E. DEAKIN, Hay Mills.

Mr. T. JONES won 1st prizes in classes provided for single vases of (1) Miss Milne Maslin; (2) Herbert Smith; and (3) Primrose Countess Spencer.

Mr. JOHN HAYCOCK, Wrexham, had the best vase of White Countess Spencer.

HONORARY EXHIBITS.

Messrs. GUNN & SONS, Olton, Birmingham, had an imposing exhibit of Roses and hardy flowers. The group had a frontage of about 50 feet, and the flowers were arranged with great skill. Nearly half of the entire exhibit consisted of Roses in great variety, displayed in vases, baskets and tall stands, over which large arches, clothed with huge trusses of Dorothy Perkins, were a feature. The hardy flowers comprised handsome bunches of Lysimachia clethroides, Veronica, and a rich selection of Phloxes, &c. (Gold Medal.)

Messrs. W. H. SIMPSON & SON, Birmingham, sent a large collection of Sweet Peas, in which Dudley Lees, Helen Lewis, Sutton's Queen, Mrs. Harcastle Sykes, Frank Dolby, and Helen Lees were meritorious varieties. (Silver-Gilt Medal.)

Messrs. ROBERT SYDENHAM, LTD., had a large assortment of rustic silver stands decorated with Sweet Peas. (Silver-Gilt Medal.)

Mr. S. MORTIMER, Farnham, Surrey, had flowers of show and Cactus Dahlias in great variety. (Silver-Gilt Medal.)

BRITISH GARDENERS' ASSOCIATION (LONDON BRANCH).

AUGUST 8.—A profitable and instructive outing of members of the above branch took place on the 8th inst., when Finsbury and Waterloo Parks were visited under the guidance of their superintendents. On reaching Finsbury Park the party was met by Mr. J. Melville, and conducted through the principal parts of the park. The landscape effects in this park are rendered more charming by the excellent display of choice plants in both beds and borders, and seldom, if ever, has the park appeared in better condition than at the present time. The party next proceeded to Waterloo Park, where they were met by Mr. F. J. Phelps, under whose kindly offices as guide a pleasant hour was spent. The propagating department in both parks was visited by permission of the chief officer, and was much appreciated. The visitors were then shown a portion of the beds under the care of Mr. J. H. Witty.

Obituary.

JOHN WHITEHURST.—We regret to record the death of Mr. John Whitehurst at the Gardens, Oak Hill, East Barnet, Hertfordshire, on July 24. Mr. Whitehurst, who was in his 75th year, had been head gardener to Charles Baring Young, Esq., and to Charles Edward Baring Young, Esq., at Oak Hill for upwards of 40 years. Deceased was greatly esteemed by all who knew him.

ENQUIRY.

Can any reader inform me which is the largest glass structure in the world used for plant cultivation? What is the interior measurement in cubic feet? *W. A. S.*

ABNORMAL GLOXINIA. *A. J. D.* The flower presents an example of doubling, through some of the stamens becoming petaloid.

APPLE BRANCH INJURED. *W. S. B.* The damage has been caused by the larvae of the Wood-leopard moth, which was present in the centre of shoot you sent. In such cases the grub may be destroyed by running a piece of stiff wire down the burrow or by mixing a few drops of some strong poison, such as prussic acid, in water, and pouring the solution in the burrow. Be careful to use a vegetable and not a mineral poison, or you will cause injury to the tree.

BANANA. *J. W.* Bananas are certainly fruits, but they do not all contain seeds.

BEGONIA. *T. E., Windsor.* The black spots on your Begonia leaves are the sporangia of *Pilobolus torulosus*, a fungus which grows on dung. When mature, the sporangia are forcibly ejected, and attach themselves to anything which comes in their way.

BOTTLING GREEN PEAS. *W. S.* To bottle green Peas shell the Peas, put them into dry, wide-mouthed bottles, and shake them together so that they may lie in as little space as possible; cork the bottles closely, and seal the corks. Bury the bottles in the driest part of the garden, and take them up as they are wanted. They ought to keep good for some months. Or try this recipe. Choose Peas which are large and fully grown, though not old. Put them into perfectly dry, wide-mouthed bottles, shake them down, cork securely, and cover the corks with bladder. The a wisp of hay round the lower part of the bottles to prevent their knocking against each other in the pan, put them side by side in a large sauceman, and pour into it as much cold water as will reach to the necks of the bottles. Put the sauceman on the fire, and let the bottles remain standing in the water for two hours after it has reached boiling point, then take the sauceman off, but do not remove the bottles until the water is cold. Seal the corks, and store in a cool, dry place.

CHLARENTHUM QUADRANGULARE. *Sec. A. H.* *Rhaphanus cyanocarpius* and *C. quadrangulare* are distinct species. The change in the colour of the leaves of *Mutisia decurrens* is due to the extra amount of sunlight experienced this summer. This plant loves a cool, moist, well-drained soil and protection from the sun during the hottest part of the day. If you are unable to give temporary protection it would be best to transfer the plant to a position not exposed to the direct mid-day sun.

FIG LEAVES. *J. J. W.* The injury to the fig leaves is by no means rare, but it is not caused by disease. The yellowish stripes and patches are due to disturbances of the normal functions of the plants. It is generally started by

drought on grounds poor in lime. The trees should be well watered with clear water until the fruits have set, and then given a good drenching with liquid cow manure to which a quantity of lime water has been added. If you attend to the watering in this way the malady will not occur.

FUNGUS ON BRIAR. *Anxious.* Your Rose plants are attacked by the Orange rust fungus, *Uredo rosea*. All that can be done to check the disease is to burn the infested shoots and leaves and to spray the plants with potassium sulphide.

GARDENER DISMISSED. *Reader.* You had better consult a solicitor.

HORTICULTURAL FUEL. *Nemo.* At the prices quoted in your communication, coke would be more economical to use in your sectional boiler than anthracite. Should you, however, require to maintain a fairly high minimum temperature at night in your glass-houses, say 63°, during the winter and early spring months, it would be advisable to have some anthracite to make up the fire with last thing at night, as by so doing a good heat can be assured for nine or ten hours following, or longer, according to weather conditions. In reply to your second question, we should advise you to only sterilise your Tomato-borders when cleared of the crop, and to defer the application of the basic slag for a month or six weeks later. Should you use the preparation mentioned to sterilise the soil, it will not be safe to set your Chrysanthemum plants therein for a month or five weeks afterwards. Carboniciclyl may be used for the same purpose, and it will be safe to put your plants in the soil in a week or ten days after it has been sterilised. It should be used as follows. Half-pint carboniciclyl in three gallons of water, well distributed over the soil, and allowed to remain for one or two days, the soil being then raked over three times in order to work the carboniciclyl into the subsoil, after which (when the soil is drained) the hour will be ready for planting.

MORELLO CHERRIES. *D. P.* The prices for these cherries in Covent Garden market varies, as does the value of all fruits, according to the sample and the demand. They have been realising from 4d. to 6d. per lb. wholesale for best fruits. To-day (11th inst.) we are informed that they have a slightly increased value. See our weekly market report in the present issue.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is not part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon the time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time; they should be very careful to pack and label them properly, to give every information as to the county the specimens are in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *E. V. A. I.* *Epilobium hirsutum*, 2. *E. montanum*, 3. *Gasteria verrucosa*, figured in *Bot. Mag.*, tab. 837, as *Aloe verrucosa*, 4. *Polycnemum persicaria*, 5. *Hypericum quadratum*, 6. *Chenopodium polyspermum*—*W. H. Y.* *Eppactis latifolia*—*F. J.* 1. *Physostegia* (syn. *Præcoxephalum*) *virginiana*, 2. *Lycium sinense*, known popularly as the Tea plant—*Noda*, 1. *Catalpa bignonioides*; 2. *Tropaeolum tuberosum*, 3. *Ceanothus azureus*.—*Wishes.* We cannot undertake to name varieties of Roses.

PEAS. *Constant Reader.* Your Peas are affected by a fungus called "Root rot" (*Thielavia basicola*), which seems to be epidemic this season. (See *Gardener's Chronicle*, June 8, 1900, p. 361, fig. 153.) Nothing can save the crop, and the soil should be well sterilised before any other crop is planted.

PEARLGRASS CUTTINGS. *C. O. J.* It is a matter of convenience. The cuttings can be rooted successfully by either method, and you should practise that which the better suits the circumstances of your garden.

PEARLGRASS DISEASED. *W. B.* and *W. J. C.* The injury is due to a bacillus (*B. caulicola*). It makes short work of Pearlgrasses if it is once established, and you seem to have it bad enough. Destroy by fire at once all plants that are attacked, and use for cuttings those tops only that are quite free from disease. Pot five to six cuttings into 5-inch pots and do not water them until the third day afterwards. Keep on the look-out for the disease and destroy any plants that go black. Mix a little lime with the soil used for potting, and avoid using any soil in which diseased plants have been cultivated.

PRONUNCIATION OF PLANT NAMES. *D. B.* You will find a list of the principal plant names, with directions for their pronunciation, in the Appendix to Nicholson's *Dictionary of Gardening*. The subject will shortly receive attention in our own columns.

RHODODENDRON. *Pink Pearl.* By neither hand lens nor microscope can we detect anything unusual on your Rhododendron leaf. Was the wrong leaf sent?

RHODODENDRONS AND CATTLE. *W. H. Y.* Sheep and cattle do not generally injure Rhododendrons, but as they will attack almost any kind of vegetation under certain circumstances, it is advisable to protect the plants from them. They would be likely to injure the cattle if eaten in considerable quantities.

ROOTING OAK-SHOOTS. *E. B.* You appear to have done the best you could in attempting the task of rooting the shoots, but we should not have used the moss at the base of the cuttings. If you have any of the greenery left, try rooting a few of the green or soft-wooded shoots under a bell-glass. The acorns had better be allowed to mature as much as they will and then be sown at once, but success is doubtful.

SCUM ON POND. *J. T.* The green scum on your pond is probably one of the Algae. It can be readily removed by skimming the surface with a net made of sacking. The pest is also killed by diluted Bordeaux mixture, but care must be used with this substance if fish are present in the water. The operation should be repeated at intervals of a few weeks.

SEEDLING CARNAUON. *Box Rd.* The white flowers you describe as having been raised from seeds obtained from the variety *Enchantress* appear very satisfactory, but whether the variety has any commercial value or not, we cannot tell without a knowledge of the general habit of growth and constitution of the plant. If you think that the variety is better than most white tree Carnations already in commerce, you should submit specimens before the Floral Committee of the Royal Horticultural Society. You might exhibit three plants in pots and some selected cuttings.

SOPHORA MOORE-FRAXANA. *Rev. T. A. H.* This species forms a low, much-branched spinescent shrub, 2 to 4 feet in height. The flowers are white with a cup-shaped violet-blue calyx. It is figured in the *Botanical Magazine* under its synonymy *S. viifolia*, tab. 7883.

TRAY FOR VEGETABLES. *W. R. C.* We know of no standard size for a tray on which vegetables are exhibited at flower shows, but certain sizes may be cited in particular schedules. A diagram of a stand for showing vegetables was given in our issue for July 20, 1900, p. 60.

TRUSS OF RHODODENDRONS. *H. E. S., New Zealand.* The term truss is generally used in the case of Rhododendrons to describe a single inflorescence. As we interpret class 47 of the schedule you send we understand it to mean one inflorescence of each of 12 varieties.

AUTUMNAL FLOWERS.

THE desire for common flowers is one of the features of present-day home life facilitates the carrying out of decorations in the house, however extensive they may be, because the wealth of material is so abundant and varied and much of it so beautiful that autumnal floral decorations may well vie with those of any other season. It is true that, as no Rose, or hardly any, to be quite correct, is without its thorn, so autumn has its drawbacks, the worst of which is, perhaps, the numerous insects, which, while extracting a living from outdoor flowers, render many of them of little service to the decorator. This is especially the case with the large number of Composite flowers which, being fertilised by insects, remain only a short time fresh when cut, and therefore call for great care on the part of the flower-gatherer to select young flowers only, a precaution well understood with reference to spring flowers, but less practised in autumn, when it is equally, if not more, important. But to insect agency is not solely due the short life of many flowers in autumn. Some droop almost as soon as cut, and others shortly after being arranged. Mention may be made of Pentstemons, single Helianthus, double Dahlias, and Salpiglossis as markedly possessing this regrettable tendency. Probably it is a feature of most autumn flowers, though not so soon apparent as in those species mentioned, but these serve to emphasise

a condition which, I fear, many garden-decorators fail to appreciate, viz., the need of placing the cut stalks in water as quickly as convenient after being gathered. This is demonstrated by such a badly lasting flower as the Pentstemon, which, if placed at once in water, lasts for days, but if kept out of water for an hour or two is past recovery. The application is clear. Don't keep any flowers when cut out of water, but always place the stalks in receptacles filled with that liquid until the flowers are required to arrange in vases.

All through autumn, bold and elevated masses of bloom and foliage can be provided without having to depend on one or two plants, and if for no other reason, though there are others, the general character of autumnal decorations should be massive rather than slim, though the elegant habit of many of the plants of the season enables one to attain that end without sacrificing the gracefulness which is an attribute that is always expected in floral decorations.

Flowers of outstanding merit will include Gladiolus, of which alone there is an almost endless variety. Straw-coloured varieties of gandavensis should not be overlooked, nor the old Lemoinei, the novel Princeps, Hollandais, and the brightly-coloured Childsii and Goff's seedlings. These are all easy to grow, and may be increased to any extent from seeds or by the spaw, which is found at the base of the corms when lifted. With an abundant stock, one does not hesitate to cut the whole plant including foliage and flower, but if the spike only is cut, then the blades of Iris Pseudo-acorus may be used with them or those of Montbretia crocosmiflora. Tall-growing Montbretias also afford splendid material for decorations. Some of the finer varieties are now cheap enough to procure in quantity, such, for instance, as Etoile de Feu, Volcan, and Chrysis, 5-foot lengths of these being usual in even light soil. Not the least valuable property of Montbretias is that they will associate well with almost any other kind of flower. The use of Phloxes is usually demurred to on account of their stiffness; but that is mostly a matter of detail, for, provided fresh, thinly-crown spikes are employed and receptacles of bold design used, there are few flowers handsomer, probably none, than the old variety, paniculata alba. The colours are, as a rule, lovely, e.g., Sheriff Ivory, James Hamilton, Iris, Eugene Danzanvilliers, Boule de Feu, and many others. I retain in cultivation a few old varieties, such as Madame Mousset, Bridesmaid, and Bryan Wynne, which are less lumpy than newer kinds, longer stemmed, and the colours equally effective. Anemone japonica has of recent years developed into many varieties, but it is strange that one of the most effective grown here is a form given me by the late Miss Frances Hope, of Wardle, very many years ago. Queen Charlotte, Whirlwind, Lord Ardlaun, and Profusion are desirable kinds. The so-called doubles I do not care for. For making up extra large compositions, Bocconia microcarpa is quite indispensable, and for associating with it, Galtonia candicans, which should be regularly raised from seed to keep an abundant supply. Astilbe rivularis, A. Davidiana, and A. chinensis vars., with the ripened, snuff-coloured spikes of A. Aruncus; Spiraea palmata elegans, and Solidago cana-

densis and S. Shortii are all useful. There is not a large choice of blue flowers, but the now well-known Anchusa italica Dropmore variety may be named, and the very lovely and novel variety known as Opal. Butterfly Larkspur and Stock-flowered Larkspurs, the salmon-coloured and white varieties, are also essential. Pentstemon heterophylla is charming, and so are blue Sweet Peas. Single Hollyhocks seem never to have reached the position to which their merits entitle them. Old plants produce abundance of not too lengthened nor too corpulent shoots. They have to be stripped of leaves, and then they stand well in a cool apartment. Many years ago, the double varieties were used for decorating dinner tables, and were considered to be choice—an indication of how far we have progressed since then. Single Hollyhocks are really pretty, arranged on the cloth, and they have the merit of being so little known that many people fail to identify them.

There is a wealth of unsuspected charm in the tall-growing Antirrhinums, that is, the section in which the spikes run up to 5 and 6 feet high, with colours distinct and softly tinted. Those who are still unacquainted with these cannot too soon introduce a selection; the seeds must be sown in early spring, and from July till late autumn they provide beautiful flowers in almost unlimited quantity. I would like to also say a good word for the tall-growing Clarkias, white, pink, and salmon, which are altogether charming. Godetias are generally well known, but by far the prettiest of these, in my opinion, is the lovely pink G. Schaminii fl. pl. Very useful in autumn is the tall-growing Gypsophila transylvanica, one of the good things for which I am indebted to Miss Willmott. It seems almost, if not quite, identical with G. Rokejeki, the individual flowers being like those of G. Stevensii, but the general aspect of the inflorescence is greatly superior. Stems may be cut several feet in length, and these are fully furnished with side shoots, displaying each its quota of neat little flowers.

The autumn is doubly kind in giving us trailing plants, both flowering and fruiting. What so gay as the scarlet flowers and purple fruits of Tropaeolum speciosum? Then there is the glorious purple Clematis Jackmanii, and others only less desirable of the same section, the white-sprayed C. Flammlut and the common C. vitalba. Where Tamus communis can be secured, the long trails furnished with glowing fruits may be used most effectively, and within everybody's reach is the Canary creeper, one of the most useful of autumnal flowers. I say nothing of the coloured foliage, the low-growing plants, Marigolds, Tunica saxifraga, Schizostylis, Verbenas, Carnations, Tritomas, Lobelia cardinalis, Asters, Lilium tigrinum (of which splendens is probably the most effective), Helianthus, Rudbeckias speciosa, californica and japonica, and many other common plants.

A word or two on what may be called the odds and ends that can sometimes be obtained. Never neglect these. Though not to be recommended for general use, there are many flowers and leaves that may be used occasionally, which serve to break down the uniformity which a too rigid adherence to a few flowers entails. Quilled Asters, old-fashioned Dahlias, and many other species may be utilised in this way. B.

FLOWERS OF SPENSER.

(Concluded from page 124.)

RUSHES.

1. fresh flowrets dight
About her necke, or rings of rushes plight.
F.Q., II., vi. 7.
2. The knotted rush-ringes.
Shepherds Calendar, November.

SAFFRON.

And Saffron sought for in Cilician soyle.
Virgils Gnat, 87.

Though Spenser speaks of the Saffron Crocus as if it were only found in Cilicia, which he copied from Pliny and other Roman writers, it was cultivated in England as an article of commerce long before his time, and gave its name to Saffron Walden, Saffron Hill and other places.

SALLOW.

a little broke did pas
Of muddie water, that like puddle stanke,
By which few crooked salloos grew in ranke.
F.Q., IV., v. 53.

Sallow is one of the many old names for the Willow.

SAMNITES.

Mortal Samnitis. *F.Q., II., vii. 52.*

Given by Spenser as one of the poisonous plants of Proserpina's garden. It has not been identified.

SAULEGE.

The wholesome Saulge. *Maisopotmos.*

Saulge is an old form of Sage, a plant of the highest reputation for medical purposes in, and long before, Spenser's time.

SAVIN.

She gathered Rew and Savine.

F.O., III., ii. 49.

Savin is another name of the Juniper. (See Juniper.)

SAVORY.

Sound Savorie, and Bazil hartehale.

Maisopotmos.

A well-known pot-herb; formerly in much higher repute than now.

SETUALL.

Drink-quicking Setuale.

Maisopotmos.

According to Gerard and Parkinson, Setuall or Setwall is the wild Valerian.

SMALLAGE.

Stinking Smallage. *Daphnada.*

Smallage or Smallache is an old name for Parsley.

SOPS IN WINE.

1. Bring Coronations and Sops in Wine.
Shepherds Calendar, April.
2. Girlonds of Roses and Soppes in Wine.
Ibid. May.

Sops in Wine is now an entirely disused flower name; but it is mentioned by Chaucer and Bacon as well as by Spenser. It is the common garden Pink, and so is well joined with Carnations.

STRAWBERRY.

1. They all three together went
To the greene wood to gather strawberries.
F.Q., VI., x. 54.
2. Her goodly bosome, like a strawberry bed.
Amoratti, 64.

The Strawberries of Spenser's time were only the wild wood Strawberries transplanted into the garden; but from the description given of them, it is evident that, so grown, they improved rapidly.

TETRA.

Cold Coloquintida, and Tetra mad.
F.Q., II., vii. 52.

Spenser names this among the poisonous plants of Proserpina's garden. I cannot identify it, and can only suppose that it was a word invented by himself from the Latin *tetra*, i.e., horrible, offensive, etc.

THYME.

1. Bathing herself in Origane and Thyme.
F.Q., I., ii. 40.
2. Faire Marigold and Bees-alluring Thyme.
Maisopotmos.

Our common wild Thyme. We may thank Spenser for inventing such a good epithet as "bees-alluring."

TOBACCO.

Whether yt divine Tobacco were
She found and brought it to her patient
deare.
The sovaine weede betwixt two marbles
plane
She powdered small and did in peeces bruze.
F.Q., III., v. 52.

Tobacco was one of the earliest introductions into Europe after the discovery of America, and it at once was looked on as a heal-all, and was called *Herba Sancta*, or *Sana Sancta*, or, as by Spenser, the Divine Herb. It was at once grown successfully in European gardens and in England; but it could not compete with the American produce, not because it was inferior, but because, as Gerard describes it, "According to the English proverb, Ear fecht and deare bought is best for ladies."

VERVEN.

Veve-healing Verven, and hed-purging Hill.
Maisopotmos.

It is difficult for us to understand how our common Vervain or Verbenia could have been credited with so many virtues as it was, first by the Greeks and Romans, then by the Druids, and then by many mediæval writers. But in Spenser's time its reputation was fast vanishing, so that Gerard refused to mention such "old wives' fables."

VINE.

1. The Vine-prop Elme. *F.Q., I., i. 8.*
2. In green Vine-leaves he was right filly clad.
F.Q., I., vi. 22.
3. Over the which was cast a wandring Vine
F.Q., II., iv. 21.
4. A Porch with rare device
Arch over head with an embracing vine,
Whose boughs hanging downe seemed to
entice
All passers-by to taste their luscious wine,
And did them-elves into their hands incline,
As freely offering to be gathered;
Some deere empurpled as the *Uvula*,
Some as the *Arione* laughing sweetly red,
Some like faire *Emeraudes*, not yet well
ripened.
F.Q., II., xii. 54.
5. Fouth she brought the fruitful Vine.
F.Q., V., xii. 11.
6. Her deeds were like great clusters of ripe
grapes,
Which load the branches of the fruitful
Vine;
Offering to fall into each mouth that gapes,
And fill the same with store of timely wine.
Colin Clout, 60.
7. His looser locks doth wrap in wreath of
Vine.
Virgils Gnat, 15.
8. And over them spread a goodly wilde Vine.
Shepherds Calendar, August.

The vine was probably much more grown in England for the production of wine than it is now. But in all these passages the reference is to the vine of the Latin authors. Spenser certainly never saw a vine propped by an Elm, or such a vine as he describes in No. 4.

VIOLETS.

1. Fragrant Violets and Panaces trim.
F.O., III., i. 36.
2. She bathed with roses red and violets blew.
F.Q., III., vi. 6.

3. The Lily fresh, and Violet belowe.

Virgils Gnat, 84.

4. Bay leaves betwene
And Primroses greene
Embellish the sweet Violet.
Shepherds Calendar, April.
5. Of sweete Violets therein was store,
She sweeter than the Violet.
Shepherds Calendar, August.
6. Coole Violets, and Oripine growing still.
Maisopotmos.

Our common sweet wild Violet.

WALNUTS.

1. And on the other side a pleasaunt grove
Was shott up high full of the stately Tree
That dedicated is t' Olympick Jove.
F.Q., II., v. 37.
2. How have I wearied with many a stroke,
The stately Walnut tree, the while the rest
Under the tree fell all for nutes at strife.
Shepherds Calendar, December.

The Walnut introduced by the Romans was a familiar tree in Spenser's day. He got the idea of its being dedicated to Jove from its Latin name *Juglans*, i.e., *Jovis glans*.

WILLOW.

1. The Willow worne of forlorne Paramoures.
F.Q., I., i. 9.
2. To win a Willow bough, whilst other
wears the Bayes.
F.Q., IV., i. 47.
3. The utmost top of some soft Willow.
Virgils Gnat, 11.

Our common waterside Willow. (See also Palms.)

WOODBINE.

1. Others the utmost boughs of trees do crop,
And brouze the woodbine twigs that
freshly bud.
Virgils Gnat, 11.
2. As your worke all about
With woodbynd flowers and fragrant Eglan-
tine.
Amoratti, 71.

Woodbine was a general name given to almost every climbing plant, and so may mean the wild *Convolvulus* or the Honey-suckle or the wild *Clematis* or any other such plant. It cannot be certainly tied down to any.

YEW.

1. The Eugh obedient to the benders will.
F.Q., I., i. 9.
2. Long he them bore above the subject plaine,
So far as Eughen bow a shaft may send.
F.Q., I., xi. 19.

(See also Heben.)

This completes the list of plants and flowers named by Spenser. But there are a few passages in his works connected with the subject which are worth quoting.

GARDENS.

- To the gay gardins his unstaide desire
Him wholly carried, to refresh his
sprigites;
There lavish Nature in her best attire
Pours forth sweet odours and alluring
sights;
And Art, with her contending, doth aspire
To excell the natural with made delights;
And all that faire or pleasant may be found,
In riotous excess doth there abound.
Maisopotmos.

There the most daintie Paradise on ground
Itself doth offer to his soher eye,
In which all pleasures plentifully abound
And none does others happinesse envie;
The painted flowers, the trees upshooting
byes,
The dales for shade, the hills for breathing
space,
The trembling groves, the Crisall running
by,
And, that which all faire workes doth most
aggrace.

The art, which all that wrought, appeared
in no place.
F.Q., II., xii. 53.

—H. N. Ellacombe.

CAMPANULA RADDEANA.

This ornamental species belongs to the same group as *C. medium*, which is characterised by having additional calyx-lobes or appendages, as they are usually termed, alternating with the normal ones, and similar in shape, but strongly reflexed on the calyx-tube. It is a native of Borsbom, in the Caucasus, and was first described

stems are slender and slightly angular. Leaves ovate or ovate-cordate deeply toothed, glabrous. Inflorescence pyramidal, with alternating branches. Flowers blue, nodding, about an inch and a half long. This species appears to have been first cultivated in this country, at Kew (*Gard. Chron.*, 1906, xl, p. 23), where it was raised from seed obtained from the Tiflis

THE ROSARY.

WEeping STANDARD ROSES.

FAIRLY good plants of Weeping Roses may be obtained the second year from budding, provided specially selected, stout, straight, well-rooted Briars, capable of receiving four to six

FIG. 54.—CAMPANULA RADDEANA: FLOWERS BLUE.

by Frantvetter in the *Bulletin of the St. Petersburg Imperial Academy of the Sciences*, vol. x. (1866), p. 395. Unlike the Canterbury Bell (*C. medium*), this is a perennial species, and it is easily propagated by division. The plants are much branched from the base, and they grow only about 6 inches high in the wild state, but more than a foot high under cultivation. The

Botanic Garden. Colonel Beddome, who probably has the richest collection of cultivated Campanulas in existence, describes *C. raddeana* (*Journ. R.H.S.*, xxvii, p. 214) as a valuable species for the rock-garden. The plant was granted an Award of Merit by the Floral Committee of the R.H.S. when shown by Mr. G. Reuteh on June 23 last. *W. Bunting Hemby.*

buds, are used as stocks. August is the best time to insert the buds, and the earlier in the month the better. Most of the evergreen Wichuriana Roses are suitable for cultivating as weeping plants, and these include such beautiful varieties as Minnehaha, Dorothy Perkins, Lady Gay, Alberic Barbier, Alma Garnet, La. Angeline, Ferdinand Roussel, Galaxy, Paul

Transon, and W. K. Harris. Those classed simply as Ramblers are not all suitable for the purpose. Tausendschön, Philadelphia Rambler, Crimson Rambler, Trier, and Blush Rambler are not to be recommended, their growths being too coarse and rigid. Weeping standard Roses require very careful attention during the first season after they are worked, for the long shoots are very liable to break off if subjected to strong winds. A lath should be attached to each shoot, and this should be well secured to the main stem until the grafts have made a firm hold upon the stock. The following spring each strong shoot should be cut back to within a foot of the stem, and all weak growths should be pruned to two or three buds. The shoots as they appear during the second season should be induced to fall gracefully away from the stem; for this purpose three pieces of thin lath, each about a foot long, that have been thoroughly soaked in water, should be attached beneath the growths to the stem, endeavouring to produce an arch. A well-balanced head is easily formed, for as the shoots are placed during this second season's growth so will they remain. For the third year little or no support is required, and a symmetrical head may be expected to form naturally. Minarchea makes the most perfect weeping standard owing to its very long shoots, which produce loosely-formed sprays of rich pink-coloured, double flowers. The richly-coloured single-flowered Hiawatha is another valuable variety, producing huge trusses of crimson flowers that are much enhanced by a conspicuous bunch of golden stamens; the flowers are long-lived. The variety Paul Transon makes a charming weeping plant, its shiny green, leather-like foliage being persistent throughout the winter, and producing its pretty rose-coloured, tea-scented flowers in great abundance from June to November.

NEW MINIATURE STANDARD ROSES.

MINIATURE standard Roses are admirably adapted for bedding purposes, where they may be used to relieve dwarter plants. They appear best when associated with low-growing members of their own class, and should be planted at rather wide intervals over the whole bed. They also form charming subjects as pot plants for a dwelling-room or for grouping. A valuable feature is their continuity in flowering, for if treated under glass and properly cultivated they will produce a third, and even a fourth, crop of flowers during one season, and two or three bloomings when grown outside under ordinary conditions, with a slight pruning after each flowering. The stock used for these small standards is the Manetti, and stocks are especially grown for this purpose, being usually from 2 to 3 feet high. The class of Rose suitable for this system of culture is a somewhat limited one, being confined to the dwarf Polyantha varieties of lesser growth, such as Annie Muller, Baby Dorothy Perkins, Mme. N. Levasseur, Eugene Lamesch, Léonie Lamesch, Mrs. W. J. Cutbush, Princess Ena, and Schneewittchen. *Wm. Mallett.*

THE ROSE SEASON IN SCOTLAND.

In south-western Scotland Roses have not been quite so numerous this year as in former seasons, but they have, in many instances, been quite remarkable for their exquisite texture and marvellous dimensions. Those that have achieved almost nothing in the flowering direction up to this period (July 29) are, for the most part, varieties of recent origination, whose first tender shoots were seriously injured by exceptionally severe visitations of frost on the confines of May. The only new varieties that have already flowered effectively here have been Isabelle Milner, one of the loveliest of all Roses, a variety of wonderful fulness and perfect sweetness of aspect and fragrance; W. E. Lippiat, a highly effective crimson Rose; Elizabeth Barnes, of richer and deeper colour than

Mme Abel Chatenay; and Nance Christie. Perhaps the very loveliest of the Irish Roses bears the name of "Peggy," one of the many inspirers of Robert Burns. Avoca is just beginning to unfold its crimson flowers, but Harry Kirk, though its golden flowers have been long and patiently awaited, has not yet appeared. It promises, however, to be very effective during the autumnal months. A plant of Hiawatha, the most strikingly distinctive of the glossy-folaged Wichuraiana hybrids, not more than 3½ feet high, has developed 250 flowers.

Another remarkable achievement in my garden is that of the Irish Rose Margaret Dickson, which, after climbing assiduously for years through an exceedingly lofty Hawthorn hedge, has flowered this season at the height of 2½ feet. Caroline Testout is also very aspiring, and its magnificent flowers are invariably commanding in their effect. Of the many Hybrid Teas and Hybrid Perpetuals, the finest this season have been (in addition to those already mentioned) Clara Watson, Viscountess Folkestone, La France, Cho. Papa Gonet, Captain Hayward, A. K. Williams, Horace Verrier, Duke of Edinburgh, and its velvety derivative Prince Arthur, Lady Helen Stewart (one of the sweetest of crimson Roses), Duke of Albany (with wonderful colour, Hugh Dickson (with splendid texture and charming fragrance), and Gloire Lyonnaise. On the walls, my finest Roses have been Bouquet d'Or, Mme. Georges Bruant, and that lovely Hybrid Noisette, with its odororous, drooping flowers, Mme. Alfred Carriere.

Last year I described J. B. Clark in these columns as "an exceedingly large, open-hearted Rose." This grand variety, with its splendid dark-shining, plum-shaded complexion, is, I am glad to record, much fuller in the centre this season: its colour, as I have indicated, has also been much deeper and more impressive, and I cannot but regard it as a valuable acquisition. *David R. Williamson, Mansie of Kirkmaiden, Wigtownshire, Scotland.*

NOTES FROM A "FRENCH" GARDEN.

THE principal work now consists in cleansing the beds, gathering the Melons when ripe, and watering. The seedling Carrots sown a fortnight ago are growing freely; to have them ready for pulling by October they will require daily waterings during hot weather. The Melons, except the last batch planted at the end of June, are all in the open, and care must be taken to remove useless growths in order that the fruits may receive all the nourishment possible. They now require copious waterings.

We have sown a batch of Cabbage and Lettuce, the latter of the Little Black Götte variety. They will be planted at the end of August, in beds prepared to accommodate three rows of cloches. They will be set in groups of four plants to each cloche at the end of September. A batch of Carrots (Early Parisian) can now be sown in sandy soil in the open; though there is not a ready market for this batch, young tender Carrots are always welcome in a "French" cuisine. The ground for the last batch of Batavian Endive should be prepared at the earliest opportunity, as they must be well rooted by the end of August to produce a satisfactory result.

We are now preparing a seed-bed for the sowing of a dwarf strain of the Ox Heart Cabbage; the seeds will be sown at the end of August, and it is preferable to sow two to three-year-old seeds, as the seedlings from these are not so liable to bolt into flower. This variety has done well at Mayland this spring. It is the earliest Cabbage in the market.

We are now sowing a batch of Onion of the variety Little Paris Market. We have dug the ground well, and have incorporated with the

soil a layer 2 inches thick of well-decayed manure. The seeds are sown thinly, and the germination is hastened by light but frequent waterings, as the bed must always be damp. For this sowing it is preferable to select seeds as new as possible.

All the lights used in the culture of the Melons have been brought into the shed; those with broken glass have been put on one side, and during wet weather they will be repaired, as no opportunity must be lost to put all arrangements in working order ready for next January.

Where a "French" garden is contemplated it is time to lay the necessary pipes for the water supply. To obtain 2,000 gallons of water per hour it is necessary to lay a main pipe 3 inches in diameter, running parallel with the position of the future hot-beds. The side pipes should have a diameter of 2 inches and be placed 70 feet apart, which will allow 65 feet for five frames and 5 feet for a path. The hydrants should be 1½ inches in diameter and 2½ feet apart. When the water cannot be had from the main a tank 20 feet high and holding at least 5,000 gallons, supplied with a 2 horse-power motor, should be constructed. This quantity will keep a "French" garden of 2 acres well supplied with water. *P. Aquilias, Mayland, Essex, August 7.*

FREESIAS.

FREESIAS are such charming flowers both in scent and appearance, that it is surprising we do not see them taking a more prominent place in every greenhouse. The probable reason is that many people have tried them with ill-success, and therefore regard them as an unsatisfactory crop for anything except a cut flower supply of comparative unimportance. Though very easy to grow, Freesias require some care in management, and it is because their requirements are not always understood that so many people fail with them. How often one sees a pot of these plants with numerous flabby and straggling leaves hanging over the edges of the pot and a few straggling blossoms supported by stakes, the effect of which is to spoil entirely the natural gracefulness of the plant.

Those who are potting up Freesia bulbs during the next few weeks should bear in mind that the Freesia is a semi-aquatic plant, and should be treated as such if the best results are to be obtained. The bulbs, of which the largest should be selected, should be potted in nothing smaller than a 5-inch pot, and the compost should consist of one part each well-rotted cow manure and leaf-mould to two parts of rough fibrous loam, with a good handful of sharp sand to every pot. A piece of fresh turf laid upside down over the crock at the bottom of the pot will assist in keeping the roots cool and moist. The bulbs may be planted an inch deep, no more than four or five in a pot, and the soil pressed firmly around them. After potting place the pots in the open with some covering handy—a sheet of galvanised iron is excellent—to put over them during heavy rains or continued wet weather. The covering should be raised well above the pots, so as to admit plenty of light and air, and should be removed in fine weather. It will be better for the bulbs and will save watering if the pots are plunged up to their rims in ashes, the latter being kept constantly moist but not allowed to become sodden underneath the pots.

If the bulbs are potted during August or at the beginning of September, the growth should be well advanced before it is necessary to move the pots indoors. A few chilly nights will do no harm, but frost must be prevented,

and as soon as there is fear of this the pots should be put into a cold frame, the lights being removed whenever weather permits and the plants kept as hardy as possible. After a few days there a few of the strongest pots may be taken indoors and placed in a very gentle heat, 50° to 55° Fahr. being quite enough so long as there is sunshine during the day, when, of course, the temperature will rise without doing harm. Plenty of air must be given, and a little ventilation at night, but preventing cold draughts, is beneficial so long as the weather is mild. As the days get shorter and less sunny, a slightly higher temperature may be allowed, but the plants need watching, and at the first sign of weedy growth the heat should be

ate that the plants are suffering from cold, just as a delicate flabby appearance will show too much coddling. The chief things to remember in *Freesia* culture are that they require plenty of moisture with efficient drainage, an abundance of air, and a moderate temperature. They absolutely refuse to do their best when hurried.

Freσίας can be grown from seed, and the writer has had finer blooms and stronger plants under this method than by any other, but the present season is not the best for seed sowing. Whether grown from bulbs or seed, however, *Freσίας* can be had with foliage as stiff as that of *Gladiolus*, and flowers quite capable of supporting themselves. *Last Sussex.*

others with flowers whose colouring is disliked by many. There are no markedly bad white *Iris* Kemperi; all the art shades of lavender, lilac, pale blue, and deep blue are distinctly good, but among the so-called reds, purples, splashed, and parti-coloured flowers there are but few to admire, the flowers being generally inferior. We may copy Japanese gardens in every detail, skirt out waterways with *Iris* in approved Japanese fashion, but we cannot reproduce the Japanese climate that so well maintains the plants in good health in their native country. There is evidence of this in every garden in which *I. levigata* has formed part of an important scheme. In the first year or two there is a glimpse of success, but afterwards,

FIG. 55.—IRIS LEVIGATA (KEMPFER).
W. J. G. & Co. Lith.

JAPANESE IRISES.

(Concluded from page 136.)

I. LEVIGATA (I. KEMPFER).—For garden purposes *Iris levigata* is a group of garden forms derived from one species now widely known as *Iris Kemperi*—the Japanese Flag. There are perhaps a hundred forms grown in Japan. French and Dutch growers have produced a few others, but in no case is a standard of nomenclature recognised, and many fine *Iris* are lost in a maze of nondescript forms for lack of generally-recognised names by which they may be distinguished. For the present, it must suffice to say there are single and double forms in plenty, floriferous and non-floriferous forms, some with attractively-coloured flowers, and

in most cases, a gradual collapse that spells unsuitable culture. There must, in fact, be no attempt to grow *Iris levigata* in the black once characteristic of the Japanese *Iris* garden; our cold winters would tax the plants severely in such material, and experience teaches there is nothing to beat 9 to 12 inches of rich loam between the plant's root-stock and high-water level. In such a position they undergo a certain amount of ripening in winter sets in, and long experience with broad areas of Japanese *Iris* convinces me that a submerged condition of the root-stock is not conducive to success. Shade they cannot endure; persistent laying of their roots by active water represses free growth, and sour, water-logged soil induces a species of fungus to form

modified. *Freσίας* need to be kept near the glass, and coddling in any form is to be avoided. This, probably, is the cause of most failures. The earliest bulbs should begin to show for bloom in November or December, but if they are later nothing will be lost. When the buds appear, a weak solution of liquid manure, made from cow or sheep-droppings, may be given twice a week and will greatly aid the plants. Artificial manures are best withheld, for although some may be beneficial, the writer has had unhappy experience with one or two kinds, even when applied in the most careful fashion. To keep up a succession of bloom fresh pots may be introduced once a fortnight from the frame until it gets too cold to leave any outside at all. A purplish look on the leaves will at once indi-

on the leaves and rhizomes, giving them a rusty appearance that marks the beginning of the end. There is also much to be said for biennial lifting and replanting. I have noticed a marked change in the health of perfectly acclimatised plants of *Iris levigata* when they have occupied the site for three years, and this has led me to lift every plant that has flowered well for two years, break it up and replant it in soil that has been sweetened by a few weeks' exposure to air, and enriched by a liberal dressing of rotted manure—preferably that from oxen. March is a good time for this operation—autumn less good, because the plants lie dormant through the worst of the winter and occasionally suffer loss on this account. A faithful copy of Japanese *Iris* gardens could not exist in this climate for many years, whilst a modification,

restivation and the "blood-stained" spathes have earned for the variety the names *hematophylla* and *sanguinea*—names which are at present in general use. Hybrid derivations of this variety are *Blue King* and *Snow Queen*. The former is structurally between *orientalis* and *coeana*, and may prove to be a hybrid between these two. It has rich, purple blue flowers of wonderful refinement. *Snow Queen* is a valuable border plant, presumably derived by crossing *orientalis* with a form of *levigata*. It has large flowers, the blades of which are orbicular, the standards broad and erect. It is pure white throughout, save for a little suffusion of yellow at the lead of the blade. These forms of *I. sibirica* are good border plants, easy to grow and flower, and they make imposing clumps under quite ordinary border culture.

can recommend planting *Iris tectorum* in poor soil at its highest point and where shade at midsummer is ensured. *Album*, a rare white form (see fig. 57), and *litacinum*, which differs but little from the type, are the only varieties I have seen. G. B. N.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, ante, pp. 81-90.)

(Continued from page 137.)

3, SOUTHERN COUNTIES.

BERKSHIRE.—Strawberries have been excellent in quality and very plentiful. Raspberries have also been produced in great quantity, and they

FIG. 56.—IRIS TECTORUM.

on cultural grounds solely, may be expected to outlive the planter.

I. sibirica.—The easternmost forms of *Iris sibirica* differ widely from the type. They are splendid border plants, whose flowers are fairly large, and there is none of that weedy character that has rendered *I. sibirica* unpopular.

Var. coeana is a tufted plant with rigid, grassy leaves, pale violet flowers with narrow, erect standards, and orbicular blades delicately pencilled with white.

Var. orientalis is an old inhabitant of gardens. It has lax leaves in spreading tufts, stout flower spikes with characteristic ruddy spathes, from which are produced pretty violet flowers with large, drooping orbicular blades as large as a penny. The crimsoned tips of the flowers in

I. TECTORUM (*I. TOMIOPHILA*).—A fascinating *Iris*, with running rhizomes, broad sickle-shaped leaves in fan-shaped tufts and zig-zag flower-stems supporting pale blue reflexing flowers, generally splashed here and there with darker blue. They exceed 4 inches in diameter when well grown, and have toothed, white, horny crests in place of the beard of *Pogon* *Iris*es. I have seen grand clusters of flowering plants in western England, but have not seen such good specimens in the eastern counties. The species cannot withstand summer drought or winter wet, but will grow where path and border adjoin, among stones that define the edge, or at the base of a large boulder in the rock-garden. Frosts cannot harm it if the site is dry in winter. If the open garden is naturally wet in winter, I

are of first-class quality. Black, Red, and White Currants are all heavy crops, and the bunches are of large size. Sweet Cherries proved a bad set on account of a heavy snowstorm at the flowering period. F. Caff, *Charters Gardens, Ascot*.

—The Apple crop in this district is generally below the average in quantity, although there are instances of trees carrying a good crop. In these gardens they are much below an average number. Plums also are very scarce, the blooms being damaged by frost and snow at the end of April. Gooseberries are quite a failure. Strawberries have been abundant, but were very soon over. J. Howard, *Bonham Park Gardens, Newbury*.

DORSETSHIRE.—Despite very wintry weather experienced during the fourth week in April,

when many wall fruit trees were in full bloom, the general fruit crops are satisfactory. Apples are a good average crop, but the choicer dessert kinds, such as Cox's Orange Pippin, which failed absolutely last season, have excellent crops. Pears are a poor crop, and, in particular, on trees against east walls. These suffered from the severe weather which we experienced hereabouts on the morning of April 24, when we registered 7° of frost. This was preceded by several hours of rain and snow. The same frost was also accountable for the partial loss of the Plum crop. Sweet Cherries, which succeed only indifferently in this county, are better than I have ever known them. Morrellos are also good; Peaches and Nectarines are an average crop, but Apricots are almost nil. The excellent promise of a Gooseberry crop was also destroyed by the frost on April 24. Other bush fruits, including Raspberries, are good. The Strawberry crop is the most satisfactory for several years. *T. Earton, Castle Gardens, Sherborne.*

—The Apple crop promises to be a very good one, and the fruits are of fine quality, especially since the advent of rains. Pears of some sorts are a fair crop. Plums are few, the bloom was injured by a fall of snow and a severe frost during the third week of April. Gooseberries and Currants are plentiful and good. We had good crops of Strawberries, but owing to the hot, dry weather, they were soon over. *Thos. Denny, Down House Gardens, Blandford.*

—HAMPSHIRE.—Apples promise a good crop; the trees are healthy and clear of pests; varieties such as Lord Grosvenor, Lane's Prince Albert, Bramley's Seedling, Cox's Orange Pippin, and Worcester Pearmain are excellent. Gooseberries are almost a total failure, owing to the frost and snow which occurred during April. Strawberries are, as is usual here, heavy crop of fine fruit. Sir Joseph Paxton has this season once more asserted its superiority for favour over most other sorts. *E. Molyneux, Swanmore Park, Bishop's Waltham.*

—With the exception of Pears, the fruit crop generally may be taken as a good average one. Apples, in many varieties, are plentiful, the fruits being clear in the skin and the trees strong and healthy in growth. Plum trees on N. and N.W. aspects are carrying full crops, but trees on E. walls are not as well fruited. Apricots are scarce, but the fruits are good, though somewhat later than usual. Owing to the dry weather Strawberries were excellent in flavour, but the heat hastened their ripening; consequently the season was shortened. All small fruits are good, Black Currants being the lightest crop. *A. G. Nichols, Strathfieldsaye Gardens, Mortimer, R.S.O.*

—KENT.—Spring frosts damaged the crops of Gooseberries and Plums in many parts. Apples in orchards have suffered severely from caterpillars, and have, in consequence, shed their fruits freely. Plums are abundant in many places. The fruit trees in our nursery are remarkably free from aphids. *Geo. Bunyard, Maidstone.*

—Many persons are of the opinion that if Damsons are not gathered the next year's crop will be a bad one. The fruits of some of our trees were left ungathered last season, and these had a heavy crop this year, whilst others growing in a better situation, the fruits of which were gathered, have a very poor crop. The Cherry crop is very unequal; some trees are well fruited, whilst others have but few Cherries. Trees in orchards noted in the winter as being affected by disease are not much, if any, inferior in cropping to those not affected. The variety May Duke, which was quite immune from the disease, has no fruits; the trees are surrounded by other affected varieties having, on the whole, fair crops! *Alfred O. Walker, Ulcombe, Nr. Maidstone.*

All fruit trees are very clean and free from blight. I have not seen them looking so well for the past 14 years. I never use wash of any kind on my trees, which, I think, is the secret of my success. If more summer-pruning was practised and less washing, I believe the trees would be more prolific. *Wm. Lewis, East Sutton Park Gardens, Maidstone.*

—In some orchards the Apple crop is a light one, yet on the whole there is evidence of

a good supply of this fruit. Pear trees blossomed freely, but in many instances the fruits failed to set. Late Cherries were almost completely spoiled by continuous rain. *Geo. Fomell, Bowden, Tonbridge.*

—Almost all the fruit trees in this district have been badly attacked by the winter moth caterpillar. In plantations where the trees have not been washed there is no fruit, but in the well-tended plantations there are some good crops. *B. Champion, Mercworth.*

—Caterpillars are very prevalent this season, especially on Apple trees. Plum trees flowered well, and the foliage is free from aphides. Pear trees flowered abundantly, but there were no insects about at the time to pollinate the flowers; consequently the majority of these fruits dropped. Strawberries flowered unusually well, and we have had a very heavy crop; the foliage is free from mildew. Crops of Currants and Gooseberries are patchy; they are plentiful in some places about here. Raspberries are a full crop, and Cherries flowered

the trees did not flower freely, owing, no doubt, to the heavy crop of last year. Strawberries are a remarkably good crop, the berries being of fine quality. Bush fruits are plentiful and good. *John Thos. Shann, Betteshanger Park Gardens, Eastry, Dover.*

—Fruit trees of all kinds are remarkably clean and healthy this season. Bush fruits have cropped heavily, the fruits being very good. Strawberries were a record crop, and their flavour was extra good owing to the dry, sunny weather. *J. G. Weston, Eastwell Park Gardens, Ashford.*

MIDDLESEX.—Considering the severe weather experienced during the flowering period of many kinds of fruit trees, the crops are much better than was expected. Apples are a very good crop, and Peaches against south walls are plentifully cropped, but on trees against west walls the fruits are few. Strawberries were excellent; Gooseberries are an average crop, and the same may be said of Currants, Cherries, Raspberries, and Plums. The crops, on the whole, may be considered very satisfactory. *H. Markham, Wrotham Park, Middlesex.*

—Apples promise to be an extra good crop this season, but Apricots, probably owing to the excessive crop of last year, are a failure. Small fruits promised well early in the season, but the heavy fall of snow, followed by frost, on April 25, practically ruined all bush fruits. Strawberries have been very prolific, but late fruits were damaged through continued showers and dull weather. *A. R. Allan, Hillington Court Gardens, Uxbridge.*

—In spite of the heavy fall of snow and 4° of frost on April 24 the fruit crops are satisfactory. Apples are a heavy crop, especially the varieties Lane's Prince Albert and King of the Pippins, and these varieties have had to be thinned heavily. Pears vary considerably in cropping, the best are wall trees of Souvenir du Congrès and Durondeau. Pyramid trees have only a moderate crop. Strawberries escaped the May frosts, and were the best crop for years past. Laxton's Reward stands out conspicuously both for size of fruit, flavour, colouring, and cropping qualities; many of the fruits were more than two ounces in weight. It is quite the best variety here. Gooseberries, Currants and Raspberries are heavy crops and all are of good quality. *Jas. Hawkes, Osterley Park Gardens, Isleworth.*

SURREY.—The fruit crops in general are very promising, but spring frosts ruined the Apricots, Peaches and Nectarines, particularly the Apricots. Strawberries have been very good, but the late fruits, which were exceptionally numerous, were ruined by rains. A storm on July 13 caused serious damage in some of the gardens here, many Apples being injured by large hailstones. *J. Lock, Outlands Lodge Gardens, Weybridge.*

—All our fruit trees look well and promise good crops of clean fruit. Our Cherry trees have not yet attained a bearing size, but the trees are making excellent growth. *S. T. Wright, R.H.S. Gardens, Witley, Ripley.*

The fruit trees in general are making good growth, and in most cases are carrying average crops of fruit. During the nights of April 24 and 25 we experienced 8° of frost, and on the night of the 25th a heavy fall of snow. Many Plum and Pear trees were then in full flower, yet they are, in most cases, carrying good crops, although no protection was given the trees. Gooseberries and Currants that were in flower on those dates failed to set their fruits. I have noticed several Plum trees around here with silver-leaf disease, more than I have since 1904 after the sunless summer of 1903; this suggests to me that silver-leaf is in some way developed in seasons where there is an excess of moisture and a lack of sunshine. *W. P. Bound, Gattin Park Gardens.*

—I have never known Strawberries so poor in flavour as this year. Apples set a huge crop, but, happily, the fruits have thinned themselves satisfactorily. Plums have fallen from an average to an under crop, through defective fertilisation. Raspberries are a phenomenal crop. *W. Wilks, Vicarage, Shirley, Croyd.*

—The exceeding irregularity of the fruit crop this season renders it difficult to furnish a satisfactory return. There are as many Apple trees fruitless as there are specimens with good

FIG 57.—IRIS TECTORUM, WHITE VARIETY (REDUCED) (For text see p. 142.)

freely and set well. *H. Connell & Sons, Eynsford.*

—Cherries were a heavy and good crop until persistent rains spoiled them; only a small portion of the mid-season fruits were gathered, and the late fruiting varieties have also suffered from the same cause. All varieties of Strawberries have given heavy and good crops. Givon's Late Prolific, treated on the one-crop system, has done grandly. Some varieties of Apples are a full crop, but others are barren. Pears are very few, but the fruits we have are clean and good. There is a great abundance of all bush fruits, even Black Currants, which have been failures for many years. *W. E. Humphreys, Blendon Hall, Bexley.*

—The fruit crops in this district are very good. Cherries are a remarkably fine crop; Apples are plentiful and good, and Plums are also abundant. Raspberries are very heavy crops, especially of Superalive and Baumforth Seedling. Pears are not more than an average crop;

crops. Peas are very few. Plums are plentiful on Victoria and a few other varieties, but, generally, the crop of this fruit is light. Bush fruits have been remarkably good and plentiful in spite of the alarms sought to be created as to Gooseberry-mildew and Currant mite. Wall fruits are a poor crop; the intensely cold weather which prevailed in April having practically destroyed the embryo fruit generally. Strawberries have been exceptionally good and plentiful, though the season was none too long. Raspberries and Loganberries have been great crops. *Alex. Dean, Kingston.*

—The fruit crops in this locality are somewhat patchy. Apples here are a fair average crop, and the fruits mostly are a good shape and promises to finish well. Peas set fairly well, but the Pear nidge has reduced the crop. Plums are better than usual; both dessert and Morello Cherries are heavy crops and of good quality. Peaches, Nectarines and Apricots are much under last year's crop in quantity. These, as usual, failed to set owing to bad weather in the spring. Small fruits are good this year, Raspberries being extra fine and plentiful. Strawberries also were extra good, especially in point of quality. I have never known fruits of Royal Sovereign to be better in size, colour and flavour; they were much less so than usual. Other good sorts here are Givoni, Late Prolific, British Queen, Dr. Hogg, Sir J. Paxton, Louis Gauthier, Laxton's Latest, and Bedford Champion; the last-named is fine in appearance but very poor in flavour. Filberts and Walnuts are satisfactory crops. *Geo. Kent, The Gardens, Norbury Park, Dorking.*

—The fruit crops in this district, with the exception of small fruits and Strawberries, are much below the average. The majority of the Apple trees which are fruiting this season are with few exceptions, those that were barren last year, and these are greatly in the minority. *H. H. Harris, Alfordon Gardens, Putney, St. Marys, Dorking.*

(To be continued.)

MARKET PLANTS.

FATSIA (ARALIA) SIEBOLDII.

This is one of the leading market plants, the prices varying from about 4s. per dozen for specimens in 3-inch pots up to 24s. or 30s. for extra well-finished plants in 6-inch pots. The best large plants I have noticed were grown out-of-doors the previous summer, kept in a temperature just above freezing point throughout the winter, and started naturally as the weather became warmer in the spring. When growth starts in spring the plants soon develop many leaves, and at that stage liquid manure is of great assistance to them. They pay best if left until the leaves are fairly hard before sending the plants to market.

Some are raised from seeds saved in this country, but growers depend mostly on imported seeds, which come from Germany, usually early in April. The seeds soon lose their vitality, and should therefore be sown as soon as received, or if circumstances compel them to be kept for a few days they should be shut up in a tin box or a glass bottle and kept in a cool place. I have kept seeds until August, but with the greatest care they did not germinate so well as those sown as soon as received. The seeds may be sown in shallow boxes or in pans, using good loam and a surface layer of light soil that will not cake. The pans should be placed over a little bottom heat and be well exposed to the light. The seeds will soon germinate; damping is sometimes troublesome, but this may be obviated if the seeds be sown thinly and the seedlings pricked off as soon as they are large enough to handle. Although the plants are best started in the open with in warmth, at sub equant stages they make more satisfactory growth under cool treatment. Where plenty of room is available indoors they may be grown under glass, and form useful plants by the following autumn. The most sturdy plants are those grown in full exposure to the light. They are ready for sale in the second season. Plants which have been kept in small pots through-out the winter may be potted into 3-inch pots early in the year, and kept in a pit until all danger of frost is passed, when they may be stood in the open.

With careful attention to watering and full exposure to sunshine they will form short, sturdy growths and thick leathery leaves. Although established plants are quite hardy, frost will injure the young leaves and thus spoil the plants for sale, therefore they should be taken under cover early in the autumn or before severe weather sets in. The compost most suitable for *Aralia sieboldii* is a mixture of rich loam, well decomposed stable manure, and some bone-meal. *A. Howley.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALANBAND, Orchard Grower to Lt.-Col. G. L. Herberton, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Miltonia vexillaria.—Plants of this species, and its varieties, are commencing to grow actively; therefore, those in need of fresh rooting material should receive attention forthwith, as re-potting or re-surfacing with new rooting medium is best performed at this season. Young, vigorously-growing plants that require additional root room should be shifted into larger receptacles, with as little disturbance as the roots as is possible. Large specimen plants that are in wood stems of exhaustion should have the old material shaken from their roots, any useless pseudo-bulbs removed, leaving two or three only behind each lead; and all dead and decaying roots cut away, taking care not to injure any of the healthy roots in the process. These plants thrive best under pot culture. The pots should be filled to within two-thirds of their depth with material for drainage. For a potting medium use a mixture of two-thirds Osmunda rhizomes of Polypodium fibre, and one-third clean, fresh sphagnum-moss. These materials should be well mixed up and well aired together, adding a liberal sprinkling of crushed bricks and charcoal to keep it porous. Press the soil about the roots moderately firmly, and surface the pot with sphagnum-moss. After potting, the plants should be staged in a structure having an intermediate temperature, and be shaded from strong sunshine. Water must be given sparingly for some time after the plants have been repotted. An occasional sprinkling on the surface moss through a fine rose can will keep the soil sufficiently moist, provided the surroundings are kept damp.

Miltonia Bicolor.—This is a hybrid of *M. vexillaria*, and one that is rather uncertain in its flowering season. Healthy, vigorous plants often produce two batches of flowers in one season, but those that are produced in spring are by far the best. The plant needs similar treatment to that described for *M. vexillaria*, except that they should be given rather warmer quarters at all seasons. Repotting may be done at any time during the stage when new roots are forming above ground from the young growths. The plants give the best results when their roots are restricted to small pots; therefore, over-potting must be avoided.

THE FLOWER GARDEN.

By W. PATER, Gardener to Lady WASTON, Lockinge Park, Berkshire.

Early-flowering Chrysanthemums.—Many of the earliest varieties will now be well furnished with flower-buds. Some of these outdoor varieties require no thinning of their flowers, but others do need such thinning. As a rule, several buds form at the end of each shoot, and even in the axils of the upper leaves; unless some of these are removed, the blooms will be small, and many of them deformed through overcrowding. Rubbing out the buds is a simple process, but it requires care, and an inexperienced person may be liable to rub out the wrong buds. These Chrysanthemums need little staking; one stick placed at the time they are planted out will be sufficient. To this the flower shoots may be secured, a process that requires considerable care and time, but it is well worth the trouble. Green and black fly, also mildew, are occasionally troublesome on Chrysanthemums out-of-doors, and must be combated directly they are observed. Tobacco powder dusted on the leaves when they are damp is a good specific for aphids.

The Everlasting Pea (Lathyrus sylestria).—The Everlasting Pea is a fine subject for growing in masses on rockwork or for training on arbors, walls, trellises, &c. The plants are not particular as to soil, provided it is fairly rich, and they are useful for furnishing cut flowers and pretty shoots for arranging with Sweet Peas and other flowers. A common mistake in growing this plant is overcrowding the shoots, which should be well thinned out when they are young. Being a very deep-rooting plant, the seeds are best sown where they are intended to remain permanently, but they can be planted in small pots now and transplanted in the spring. There are several varieties of distinct colours, including white, pink, and purple.

Hardy annuals.—Many hardy annuals suffered early in the season from low temperatures, and later from excessive drought. It may be well, therefore, to take precaution that sufficient seeds are harvested before the flowers are all over, for the period of blooming may not be much further prolonged. Among the best hardy annuals is *Bartonia aurea*, which, although straggling in growth, blooms freely, and is valuable for massing. *Phacelia campanularia* forms a compact plant, and produces flowers of a lovely blue shade. *Oxandrytis*, *White Spiral*, *Carmine*, and *Little Prince* are all good varieties. The purple, white and yellow *Centaureas* are both free in flowering and decorative in appearance. The *Clarkia* is another favourite garden plant, the double salmon variety being especially good. *Lavatera rosea splendens* has brilliant, rose-pink flowers, which are very effective in the border. The best of the *Nemesias* are the dwarf varieties. *Linum grandiflorum* is a showy, tree-flowering, hardy annual. *Nigella Miss Jekyll* has beautiful, cornflower-blue flowers. The *Salpiglossis* is to be recommended for open, sunny situations.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STUBLING, Esq., Reir, Featherstone N.B.

Humea elegans.—Sow seeds of this plant in gentle heat, and as soon as the seedlings are through the soil remove them to an unheated frame, placing them close to the glass and shading them from bright sunshine. The soil should be damped before sowing the seeds, and these latter will only need to be covered very thinly with finely-sifted soil. As soon as the plants are large enough to handle, pot them off singly into 3-inch pots, taking every care not to break the roots in taking the plants from the seed pot. Let the compost consist of good loam, leaf-mould and sand, adding a little manure from a spent Mushroom bed. When the pots have become filled with roots, repot the plants into 6-inch pots. It is important that *Humeas* should never become severely pot-bound, as this condition causes them to lose their lower leaves. The compost used for the second potting may be a shade heavier and richer. During the winter the watering must be done very carefully, keeping the roots just on the dry side. The plants are best grown in an unheated frame until the appearance of frost, when they may be removed to a shed close to the glass in a house having a southern exposure; a cool greenhouse being suitable. In spring they will need to be shifted into 10-inch pots. These pots should first be made quite clean and each should be well drained. The soil for use at this potting may be made a little richer than that used on the previous occasion.

Roman Hyacinths.—No time should now be lost before putting these bulbs into pots or boxes. If a considerable quantity of bulbs has to be forced, I prefer to use boxes for the early stages of growth; it is very easy matter to move them up into pots before they come into flower, taking care to select bulbs of the same size and stage of flowering for each particular pan or pot. By this method the pots or pans frequently present a better appearance when the plants are in bloom than when the bulbs are grown during all their stages in pots. The bulbs may be started in any ordinary "cutting" boxes, which should contain a porous sandy compost; the bulbs should be placed at distances of 1 inch apart at first. After the rooting is completed apply a good watering, and stand them in a position where 6 inches deep of ashes or sand may be placed over them until

the bulbs commence to grow, at which stage the ashes or sand should be removed and the boxes placed in an unheated frame. When the roots have begun to extend freely into the soil the box, or boxes, should be placed in a warmer atmosphere to force the plants into flower, it being an easy matter to obtain them in bloom by the first week in November.

Cyclamen.—Plants that were planted out into a frame are now growing freely and should be given a little liquid manure.

Stove and greenhouse creepers.—Climbing and creeping plants in the stove and greenhouse that have made large quantities of growth should have some of the shoots cut out and the remaining ones tied in and regulated, so that the light may penetrate more freely between the branches, and thus benefit the plants that are growing beneath them. Lapagerias that are trained over a trellis immediately under the roof should have many of their growths loosened that they may be allowed to hang down before they come into flower; but great care must be exercised in order not to rub off the flower-buds whilst drawing the shoots from the wires.

Winter-flowering Begonias.—Plants that have filled their pots with roots should now be fed regularly with liquid manure, and the shoots should be neatly cut to form good specimens. The plants will not need to be syringed overhead so frequently after this date, and as the days become shorter syringing may be discontinued. Allow plenty of space around each plant and commence now to expose them a little more fully to the sunshine.

Souvenir de la Malmaison Carnation.—Any old plants that have passed out of bloom and require re-potting should be given attention at once. A suitable compost will be one consisting of turfy loam, leaf-mould, lime rubble, wood ashes, and as much sand as will keep the whole of the materials porous after firm potting has been done. In the process of re-potting be very careful not to break the old ball of soil, nor to loosen the plant at the neck. See that the roots are in a moderately moist condition before attempting to re-pot them. Provide each pot with perfect drainage, and in potting press the soil firmly round the sides of the pot. Use great discrimination in the affording of water after the operation, for during the winter the plants thrive better if kept slightly on the dry side.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Winter-fruiting Pineapples.—A tolerably dry atmosphere is necessary for plants of Smooth Cayenne and other winter-fruiting varieties during the flowering period. The house should be ventilated early in the morning upon bright days, and closed sufficiently early in the afternoon that the atmosphere of the house will rise considerably from sun heat. Enough fire heat must be employed at night to prevent the atmospheric temperature from falling below 70°. When the flowering period has passed (it may already have passed in some cases) increase the atmospheric moisture and syringe the surfaces between the plants, slightly spraying over their heads in the afternoon as soon as the house has been closed. Be particularly careful not to let the soil in the pots become dry or remain for any appreciable period in a state of wetness. Slightly stain the water with Peruvian guano each time water is afforded. It is necessary to leave sufficient suckers on the plants for future requirements, and in the case of the Smooth Cayenne variety there is a difficulty at times in procuring as many as are necessary, crowns having sometimes to be saved to make good the deficit. In this respect the Smooth Cayenne produces equally as good fruits as do suckers, but they take a longer period than is required by strong suckers. As the days shorten, gradually train the plants to absence of shade by not using the blinds so early in the day, and by removing them earlier in the afternoon.

Queen Pineapples.—Young plants intended for fruiting early next summer, having now made good progress in their final pots, will require more frequent supplies of weak tepid guano water, care being taken to prevent the soil remaining long in a wet state. At this season the

damping of suitable surfaces to promote the necessary amount of atmospheric moisture needs frequent attention, and the plants should be lightly sprayed overhead when the house is closed early in the afternoon. Ventilation should be employed early each morning, increasing the amount until the middle of the day. By closing the house early in the afternoon, sun heat may be saved, which will render it unnecessary to employ a great amount of fire heat at night. It is desirable to obtain strong plants by October, such that, after passing through a season of rest, will show inflorescences without first making new growth. Remove any suckers as soon as they appear, for if they are numerous, as is the case sometimes with this variety, they are detrimental to the plants.

Fruit borders.—The continuance of dry weather in some districts has rendered it necessary to water outdoor fruit borders even more than is usual. On no account should borders containing the roots of vines, especially such as are carrying late crops of fruits, be allowed to become dry. For if this takes place, and the soil afterwards is saturated, either by rain or by artificial watering, the berries would be very liable to split. The mulching of borders of this description with suitable manures is of great assistance to fruit trees in seasons like the present, but it is a question if the practice is not sometimes carried to excess in wet seasons.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The Dowager Lady Newnesbury, Waterbury, Yorkshire.

Pears.—The returns published recently in these pages show how unsatisfactory the Pear crop is in all parts of the country, but more especially in Scotland. The few trees carrying good crops should be well looked after, keeping them clear of breast-wood, and watering the roots as often as necessary. The trees should be relieved of all small and deformed fruits, which are numerous this year, although the crop is light. The earliest varieties, including Doyenne d'Été, Citron des Carmes, and Jargonelle, will soon be ripening, and will therefore, require almost daily attention to gathering. Jargonelle, Clapp's Favorite, Williams' Bon Chrétien, and, indeed, most of the early varieties of Apples and Pears are best gathered before they are fully ripe, as their flavour is then retained to a fuller degree. It will be necessary to carefully net the early varieties to protect them from tits and blackbirds, for once the fruits are pecked by birds, then hornets, wasps and flies gain an entrance, and soon make a clearance upon trees carrying only light crops. It is now time to pay special attention to mid-season and late-fruiting kinds by feeding the roots with liquid or artificial manures, and mulching the ground, varying the treatment according to the kind of stock the trees are worked on and the nature of the soil they are growing in. Many other details claim the attention of the cultivator at this busy season, and watering is, therefore, often neglected until it is too late to be of much benefit. It will be found that the recent rains have been beneficial to penetrate much below the surface. A special effort should be made to water those trees carrying heavy crops first, pushing the work forward at every opportunity until all have been watered. It is only by making special endeavours in this way that fruits of a large size and extra quality can be obtained. The same attention should be given to early and late varieties of Apples, both on walls and in the open quarter.

Loganberries.—These plants require much the same treatment as Raspberries. All the old fruiting growths should be removed as soon as they have been cleared of fruit to make more room for the young shoots for fruiting next year. Secure five or six of the strongest to the trellis or poles according to the space available, to prevent their being damaged by winds, and apply liberal supplies of liquid manure or other stimulants to the roots. The same treatment should be given to Blackberries. Both plants being gross feeders, they require liberal treatment, especially when planted on light, poor soils.

Nuts.—These present a poor crop this season, especially Walnuts, but the bushes of Cob and Filberts must not be neglected. Keep all sucker

growths removed from the base. A sharp look-out should be kept for squirrels, or they will soon take what few nuts there are present on the bushes.

Fruit room.—If the cleaning of this structure has not already been done, no time should be lost before thoroughly washing the shelves and all other woodwork with soft soap and water. Lime-wash the walls and have everything clean and sweet by the time the fruits are ready for gathering.

Hoing.—The ground is becoming very dry, and, if the hoe is not kept frequently at work, the surface soil will crack, and the trees will suffer at a time when moisture is necessary for the trees to complete their growth and develop flower-buds.

THE KITCHEN GARDEN.

By E. BERRETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Tomatos.—Seldom have the weather conditions been more favourable for the culture of Tomatos out-of-doors than this season. The plants are heavily laden with well-developed fruits, and, provided the weather of autumn is fine, the crop will mature well. Strict attention must be paid to the removal of all unnecessary shoots and any flower trusses that develop after this date. At this period the leaves should be shortened half-way in order that the fruits may have the fullest exposure to sunshine. The fruits must not be allowed to remain after they show signs of colouring, but should be gathered and placed in a warm glasshouse or dwelling-room, where they will mature perfectly. Tomatos grown under glass have needed very little artificial heat, and have done remarkably well. Those in full bearing should be liberally fed with some manurial stimulant, and a free circulation of air should be permitted throughout the house both day and night. Carefully prevent an excess of moisture at the roots. When the weather is wet or cold, especially at night time, a little artificial heat should be provided as a precaution against disease which is favoured by cold and damp. Plants intended for fruiting early in winter should now be shifted into their fruiting pots. These plants should be encouraged to make sturdy, short-jointed shoots. Keep them in a cool greenhouse for about a month, and after that period transfer them to an intermediate-house, where they may be allowed to fruit, training the shoots near to the glass. Make a small sowing of the variety Sunrise, placing the seed pans in a little heat. This is an excellent variety to produce an early spring crop, and, if seeds are sown at this time, the plants will become well established before the winter sets in. If they are placed near to the glass, and given every encouragement, they will be ready early in the new year for shifting into their fruiting pots.

French Beans.—In order to maintain a supply of this vegetable all through the winter, seeds should be sown now in heated pits at a distance of from 18 inches to 2 feet from the glass. No forcing whatever must be practised, but the seeds must be allowed to germinate naturally, as the hardier and more gradual the growth the better will be the results. There are many suitable varieties for winter cropping, but I prefer No. plus Ultra and Canadian Wonder. Both possess a robust constitution, as well as free-cropping qualities. They should be sown in cold frames, the lights of which should be entirely removed during the present month.

Winter Greens.—If by any chance the planting of these has not been completed, it should be done without further delay, and any failure in the principal batches should be made good. In cases where the plants have been placed in soil which has since become calked, such as between rows of Peas, the surface of the ground should be broken up with a fork, as much as make it tidy as to stimulate growth.

Greens and Lungbins.—These have done much better this year than last season, and a fine crop of fruits is now developing, but it must be borne in mind that the keeping qualities of the Cucurbitaceous fruits greatly depend on the thorough ripening. For this reason everything should be done to expose the fruits to the sun as much as is possible, elevating them well to the light and removing any surplus growths and leaves.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor, early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs dealt with the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, AUGUST 22—Derbyshire Agric. and Hort. Soc. Show at Osmaston Park, Derby (2 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—60.6°.

DIURNAL TEMPERATURES.—LONDON.—Thursday, August 19 (6 P.M.): Max. 65°; Min. 52°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, August 20 (10 A.M.): Bar, 29.9; Temp, 61°; Weather—Slight rain.

PROVINCES.—Thursday, August 19 (6 P.M.): Max. 65° Ireland, S.W.; Min. 53° Scotland, N.

SALES FOR THE ENSUING WEEK.

MONDAY, WEDNESDAY AND THURSDAY—Great Trade Sales of Dutch Bulls, at 67 & 68, Cheapside, E.C., by Frotheroe & Morris, at 10.

WEDNESDAY—Palms and Bays, at 67 & 68, Cheapside, E.C., by Frotheroe & Morris, at 5.

FRIDAY—Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Frotheroe & Morris, at 12.45.

The subject of plant pathology is one which merits the closest study, and, fortunately, its importance to cultivators is year by year receiving more recognition.

Many cases could be cited in which serious loss might have been avoided if the results of scientific investigations had been taken into account. A notable instance is afforded in the history of the "wart-like disease" of the Potato, which is also known as "black scab," and has assumed such alarming proportions that it has been scheduled by the Board of Agriculture under the Destructive Insect and Pests Act.

The disease is characterised by curious wart-like excrescences proceeding generally from the front end; outgrowths may also break out from other parts of the tuber, and in severe cases the whole Potato may be transformed into a misshapen mass of irregular, tumour-like swellings as shown in the illustration at fig. 58. The abnormal protuberances are due to excessive cell-division, the result of irritation set up by the invasion of a parasitic fungus (*Chrysophyctis endobiotica*). This parasite first attacks the Potato at the "eyes," and exists as a plasmodium in the diseased tissues. Towards autumn innumerable large resting spores are formed, which remain dormant in the soil during the winter. Professor Potter has proved by experiment* that these resting

spores are capable of infecting the succeeding crop, and it said that even after six years they may still retain their vitality in the soil and attack the next crop.

The disease first appeared some twelve years ago, and was then only known in a small part of Cheshire and North Wales. It has now greatly extended its area in these districts, and has gained a strong foothold in Cumberland, Westmoreland, Nottingham, Lancashire, and in the Midlands of Scotland. The outbreaks in all these counties have been very severe, and from all accounts the disease is spreading rapidly in the infected areas, the amount of damage increasing each year. So much is this the case that many allotments have had to be given up, as it was found impossible to grow Potatoes in the infected soil.

In the earliest stages of the disease very small outgrowths and a discoloration of the tuber near the "eyes" may be the only indication of its presence. Such specimens, however, contain numberless spores, and it is against the introduction of such infected

deux mixture for about 18 hours, or in .4 per cent. formalin for two hours to be efficacious in destroying the spores without causing injury to the tubers.

Potato tubers that are used for planting should first be very thoroughly examined, and those showing even the slightest trace of disease should be rejected. It cannot be too strongly insisted upon that all diseased tubers should be carefully collected and destroyed. They should never be allowed to rot on the land or be used as food for stock. Many Potato diseases are, without doubt, spread in this manner from year to year.

THE NATIONAL CO-OPERATIVE FESTIVAL SOCIETY'S FLOWER SHOW, to be held at the Crystal Palace to-day, the 22nd inst., represents the coming-of-age celebrations, and promises to be very successful. We are informed that the number of entries is large, and that the exhibition will include other attractions besides the exhibits of garden produce.

FIG. 58.—BLACK SCAB OR WARTY DISEASE OF POTATO.

seed tubers that growers must be specially warned lest it escape notice.

Another disease of the Potato which seems likely to cause considerable loss is the "corky scab," due to a parasitic fungus (*Spongospora solani*), allied to *Plasmodiophora*, which causes so much destruction to cruciferous plants. For the life history of *Spongospora* we are indebted to Professor Johnson, of Dublin. In the first stage the skin of the potato is raised as a small blister, and later on depressions as much as an inch in depth are produced. In these hollows, spore-balls, formed by hundreds of spores loosely packed together, are to be found. When ripe they lie freely upon the surface of the Potato; thus some fall on to the ground, while others adhering to the tubers may be carried away, and should such tubers be used for seed purposes they will certainly infect the crop in the succeeding season. This fungus has proved to be a very destructive parasite in Ireland, and it is present in the Lowlands of Scotland. Dr. Johnson found that soaking the Potatoes in a 2 per cent. Bor-

OUTING TO A NURSERY.—Members and friends of the Sutton Coldfield and District and Walsall and District Gardeners' Associations to the number of about 150, visited on Monday, August 10, the seed warehouses at Wordsley and the seed farms and trial grounds at Kinvor of Messrs. WEBB & SONS, Wordsley, Stourbridge. At Wordsley the party was met by Mr. EDWARD WEBB, and the heads of departments conducted the visitors through the offices, warehouses, and greenhouses. From Wordsley they resumed their journey to Kinvor, where luncheon was provided by Messrs. WEBB & SONS. The party then left for an inspection of the trial grounds.

SHOW OF FORCED BULBS.—As we announced in the issue for June 13, p. 385, the Council of the Royal Horticultural Society have decided to hold on the same date, when the prizes offered by the Dutch Bulb Growers' Society at Haarlem will be completed for, viz., March 9, 1909, a general exhibition of forced spring bulbs, with a view to specially demonstrating which varieties are best suited for forcing. Exhibits of small collections are invited from amateurs and trade growers, and for these medals will be awarded according to merit.

*The "Warty Disease" and "Corky Scab" of the Potato, by Prof. M. C. Potter. Journal of the Newcastle Farmers' Club.

FLOWER SHOW AT THE FRANCO-BRITISH EXHIBITION.—An exhibition of plants, flowers, fruit, and vegetables will be held under the auspices of the Franco-British Exhibition, Shepherd's Bush, on September 30 and October 1 and 2. The show will again take place in the Palace of Music and Congress halls. All particulars can be obtained on application to the SUPERINTENDENT OF HORTICULTURAL SHOWS, Executive Offices, Wood Lane, Shepherd's Bush, W.

AMERICAN GOOSEBERRY-MILDEW IN ESSEX.—We are asked by the Board of Agriculture and Fisheries to announce that the presence of the American Gooseberry-mildew in a plantation in Essex has been confirmed. An order of the Board requires all occupiers of premises on

THE MOAT GARDEN, WINDSOR CASTLE.

(See figs. 59 and 60, also Supplementary Illustration.)

This garden, which adjoins the residence of General Sir Dighton Probyn, V.C., Keeper of His Majesty's Privy Purse, is situated beneath the walls of the great Round Tower of Windsor Castle. The greater part of it is formed out of a steeply-sloping, semi-circular bank, around which paths have been made at different heights. From each pathway the ground immediately above has been so treated that it forms excellent sites for the cultivation of Alpine plants and dwarf shrubs. Looking at the garden from any point of view, one cannot fail to be impressed by its interest and beauty. There are thousands of the best varieties of herbaceous, Alpine, and rock plants, planted

pathways ornamented with suitable plants, the effect being just as if the species growing above had seeded carelessly on the ground below. Emerging from "Sandringham Court," the next scene is that of the "Riviera" garden, which is represented in the Supplementary Illustration. In the background, and directly beneath the walls of the tower, may be seen large growing plants of *Arbutus*, *Lilac*, *Crataegus*, and other species, and at the highest point shown in the picture an *Olearia* may be detected in bloom. At lower positions on the bank smaller and choicer plants abound, such as *Andromeda*, *Kalmia*, *Olearia Haastii*, *O. stellulata*, *O. nummularifolia*, *Enkianthus campanulatus*, *Citrus trifoliata*, *Choisya*, *Veronica*, *Raphiolepis ovata*, and others. In this

FIG. 59.—"SANDRINGHAM COURT" IN GENERAL SIR DIGHTON PROBYN'S GARDEN AT WINDSOR.

[Photographed by special permission.]

which the mildew exists to report the presence of the disease under a penalty of £10. All growers of Gooseberries are advised to apply to the Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W., for a leaflet describing the appearance of the disease and giving the precautions that should be taken.

WISLEY STUDENTS AT CRICKET.—The students at the Royal Horticultural Society's grounds at Wisley engaged in a cricket match with the tradesmen of Ripley at Ripley on Wednesday, the 12th inst. The students scored 112 runs for the loss of nine wickets, their opponents replying with 86 runs. The highest score was made by Mr. S. GORRINGE, who opened the batting for the students and carried his bat, making 62 runs.

with infinite care and discrimination in what may be fitly described as a wonderful garden. It is a garden full of pleasant surprises, and the visitor must traverse its many intricate and winding paths from end to end in order to see all the features of which it is composed. Many tons of stone have been brought from Norfolk for the formation of rockwork.

On entering the garden from the side farthest from the residence, the visitor passes through a charming little rock-garden known as "Sandringham Court," which is illustrated at fig. 59. Amongst the many choice plants to be seen there are species of *Sempervivum*, *Androsace*, *Draba*, *Sedum*, *Campanula*, *Saxifraga*, *Primula*, *Heuchera*, *Thymus*, *Dianthus*, *Opuntia*, *Nepeta violacea*, &c. It will be seen that even the stone

"Privy" garden also, which is situated at the foot of the bank, is a pergola clothed with many choice climbing and creeping plants. The sundial in the foreground is reputed to be 800 years old. From the "Riviera" garden commences the "Lavender Walk," so named from the quaint brick vases filled with Lavender which have been placed on each side at frequent intervals. On the left side of the walk is the border of herbaceous plants, containing a choice collection of species and varieties. When we were privileged to visit the garden in June there were flowering some beautiful varieties of *Dolichium*, also *Archusa italica* "Poppo more variety," species of *Potentilla*, *Campanula*, and *Malvauxia campanuloides*, *Gillettia trifoliata*, and others. On the opposite side of

the walk is a mixed border of the best Hybrid Tea and Hybrid Perpetual Roses. A bog-garden is the next item of interest. This is filled with groups of *Astilbes*, *Saxifraga peltata*, *Sarracenia purpurea*, *S. flava*, *Rodgersia podyphylla*, Japanese Iris, *Cimicifuga dahurica*, *Lobelia fulgens*, *Lycopodium*, *Lythrum*, *Eulalia*, &c. Tiny watercourses running over the surface of a low stone wall which surrounds it greatly enhance the effect, and serve the purpose of irrigation. At the head of this garden are Lily tanks filled with *Nymphaeas* and other aquatic plants that are arranged with excellent effect. Around these tanks are cultivated British Ferns, among which were noted some good specimens of the Crested Lady Fern (*Athyrium filix femina cristata*). From this point can be seen a series of dripping wells, the water commencing at the top of the hill and running down in irregular fashion, eventually emptying into the bog-garden. A Sweet Briar walk, planted on each side with Penzance Hybrid Briers, which are trained on a wire fence, lead to the top of the hill directly underneath the ramparts of the tower. The walls of the tower are covered with climbers some 20 feet high. These include *Polygonum Baldschuanicum*, *Vitis purpurea*, *V. Coignetii*, and Roses. One large single pure white variety of Rose named Alice Grey was in splendid condition, although it must have been planted many years ago. A very large Fig tree growing up among the obsolete canons which peer over the ramparts is effective.

The subject of the illustration at fig. 60 is the "Fountain Walk." This is one of the prettiest views in the garden. Here is an old-fashioned border of herbaceous plants, filled with many choice specimens. An antique fountain of beautiful design can be seen projecting from the wall. Old-fashioned plants, including the Lavender and Rosemary, grow carelessly from the top of the wall. Overhead are arches covered with rambling Roses, Clematis, Loganberry, and Wireberry. Wall-gardening is carried out with excellent effect.

There are many other interesting features in this unique garden. In the "Poets' Corner" are quotations from the favourite poets, including Tennyson, Longfellow, Keats, Ruskin, and others; but these are features that are of a more or less private nature. They indicate the exceedingly close attention the garden reeves from Sir Dighton Probyn, who spares neither expense nor trouble in the maintenance of the attractive garden he has himself formed.

HOME CORRESPONDENCE.

The Editor does not hold himself responsible for the opinions expressed by his correspondents.

LIBOCEDRUS MACROLEPIS AND OTHER SPECIES.—This is one of the many beautiful subjects that we owe to the enterprise of Messrs. Veitch in sending a traveller to explore the little-known districts of Central and Western China. The best known, and the hardest member of the genus is the Californian *Libocedrus decurrens*, which forms a stately columnar tree of high ornamental value. There is no other hardy Conifer with which it can be for one moment confounded, though, unfortunately, the name of *Thuja gigantea* was at one time applied to it, and in this way a good deal of confusion has existed between two distinct and equally beautiful trees. *L. chilensis*, which occurs on the lower slopes of the Chilean Andes from Valparaiso southwards to Valdivia, is very ornamental when in a flourishing state, but in this condition it can only be met with in particularly favoured parts of the British Isles. In a paper on "Ornamental Trees and Shrubs at Castlewellan," published in the *Journal of the*

Royal Horticultural Society a few years ago, Earl Annesley speaks favourably of its behaviour in that part of the sister Isle. *L. tetragona*, from Southern Chili, is much less satisfactory in this country than the preceding species, and is very rarely seen. *L. Domiana*, a native of the North Island of New Zealand, is also tender, and must be regarded more as an ornamental subject for the conservatory. The frolic-like branchlets of this plant are of a beautiful rich green colour, and, given glass protection, it is very beautiful. *L. macrolepis* is scarcely hardy, but it is well worthy of association with the greenhouse Araucarias. Messrs. Veitch, in the *Journal of Horticulture* state that it was first discovered in the Chinese province of Yunnan by Dr. Anderson, who was attached as medical officer and naturalist to an expedition under Major Sladen, 1870-1871, but it was left for Mr. Wilson a few years later to introduce it to this country. II.

GRAPE GROS GUILLAUME AT HOWDEN, YORKSHIRE.

—This large bunched variety of Grape is growing splendidly in the gardens of G. H. S. W., Esq., at Howden. The best vine is planted at the back of a roomy three-quarter span-rooted vinery, where it covers a roof space of 120 square feet, the training being on the extension system. The stem, at 1 foot from the ground, has a circumference of 10 inches and the approximate number of bunches produced annually for many years past is 15. The average weight of each bunch is from 4 to 5 lbs.—the heaviest bunch weighed 9½ lbs. The vine has been planted 30 years, and the crop this year is a good one, though the bunches are not so large as I have seen them on a former occasion, which was more than 20 years ago. Even experienced gardeners have at first sight thought the bunches to be fine examples of Black Hamburgh, owing to their compact shape and regularity of berry. The front portion of the vinery is planted mainly with Black Hamburgh, which ripens about the beginning of July, the *Gros Guillaume* maturing a few weeks later. Mr. Biskey, the manager at Howden, has exhibited Grapes at flower shows for many years, and they have seldom been beaten. There are several other vineries filled with *Gros Colmar*. All the Grapes are grown for market purposes. The soil in which the vines are growing is a deep alluvial deposit. If my memory serves me right, there was a discussion many years ago in the *Gardener's Chronicle* respecting a new variety of the Grape in question sent out or exhibited from some garden near Belfast. As some persons have suggested that the vine at Howden is a distinct variety, there may be some connection in this instance. *Yorkshire Gardener*.

MANDEVILLA SUEVEOLENS IN THE OPEN IN IRELAND.

—A large number of interesting and beautiful features are to be found in the gardens of Mr. R. H. Beamish at Ashbourne, Co. Cork, Ireland, and not the least interesting to me, on a recent visit, was a fine plant of *Mandevilla suaveolens* growing against a rock face in the rock-garden there. It is facing almost due south, and is well protected from north and other cold winds. One could not wish for a finer or more beautiful climber than this sweet-scented species, which in such surroundings is delightful in the extreme. The great trusses of pure white flowers were deliciously fragrant, and the plant contrasted well with the grey rock against which it grew. The plant has reached a good height, and it is intended to allow it to mount still higher, by carrying one of its stems under a path which traverses the rock face immediately above, and under which it has been kept. Should this be arranged, and the plant remain as healthy and hardy when it reaches a greater altitude, the picture will be a magnificent one, and there will doubtless be many other cultivators in favoured gardens who will attempt to grow this tender shrub or climber in a similar way. *S. Arnott*.

TRADE NOTICE.

Mr. S. GROUT, eldest son of Mr. GROUT, has been admitted a member of the firm of Messrs. STANS & GROUT, Seed Growers and Merchants, Emburyan (Holland).

SOCIETIES.

ROYAL HORTICULTURAL.

AUGUST 18.—The exhibition in the Horticultural Hall on Tuesday last was again a small one, and was attended by few visitors. There were, however, several good groups of plants and fruits, although none was of outstanding merit. The various Committees all made awards to novelties, the ORCHID COMMITTEE conferring no fewer than one First-Class Certificate and five Awards of Merit; the FLORAL COMMITTEE granted Awards of Merit to a new Pink and a species of *Thalictrum*; the FRUIT AND VEGETABLE COMMITTEE conferred the same distinction on a new early dessert Apple. At the afternoon meeting of the Fellows, a paper by Mr. J. Hudson, V.M.H., on the cultivation of Cherry trees in pots, was read by Mr. A. H. Pearson.

Floral Committee.

Present: W. Marshall, Esq. (in the Chair), and Messrs. Geo. Paul, W. J. James, E. H. Jenkins, W. P. Thompson, J. T. Bennett-Poe, Chas. E. Shea, Chas. Dixon, T. W. Turner, W. Bain, R. Hooper Pearson, J. F. McLeod, C. Black, C. E. Pearson, C. R. Fielder, E. J. Bowles, W. Barr, Jas. Walker, H. B. May, and C. T. Drury.

Mr. L. RUSSELL, Richmond, Surrey, showed new species and varieties of hardy Heaths, a batch of plants of *Fuchsia triphylla*, and, as a separate exhibit, varieties of hardy Fuchsias. Amongst the Heaths we noticed *Erica vulgaris* alba, *E. stricta* alba, *E. vagans* carnea, and *E. vulgaris* Hammondii. The hardy Fuchsias embraced many varieties of *F. macrostema*, including *Riccartonii*, *gracilis*, *globosa*, *coccinea*, &c. (Silver-Gilt Banksian Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, showed a very large group of *Codiaeums* of various tints. The plants were handsomely coloured, and represented most of the choicer kinds in commerce. The exhibit was arranged on the floor of the building, a number of plants being grouped higher in the centre, and also at either end. At intervals in the exhibit were arranged tall-growing plants, whilst other specimens were elevated on stands. Choice Ferns and small Palms were utilised throughout the group, which was very cleverly arranged. (Silver-Gilt Flora Medal.)

Messrs. CARTER, PAGE & CO., 52 and 53, London Wall, E.C., showed vases of *Pompon Dahlia*, pot plants of *Kochia scoparia*, bunches of *Viscaria oculata* in variety, and *Nigellas* Miss Jekyll, *hispanica*, and *h. alba*. The *Viscarias* represented a good selection of varieties, the best being labelled *corœula*, *rosea*, and *roscana*. Messrs. CARTER PAGE also showed a large exhibit of *Cactus Dahlias*, many varieties of *Volias*, and an interesting collection of ornamental grasses. The best of the grasses were *Bromus purpureus*, *Lamarkia aurea* (*Chrysurus cynosuroides*), *Panicum colonum*, *Setaria alopecuroides nigra*, *Polygonum Monspelienis*, *Eileusine rigida*, and *Agrostis dulcis*. (Silver-Gilt Banksian Medal.)

Messrs. JOHN PEED & SON, West Norwood, London, showed a group of *Caladiums*, having fine specimens of choice varieties, arranged with Ferns, Palms, *Isolepis gracilis*, and the small-leaved *Caladium argyrites*. (Silver-Gilt Banksian Medal.)

Another group of these showy foliage plants was put up by Messrs JOHN LAING & SONS, Forest Hill, London. (Silver Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, filled a large table with *Dahlias* and *Cannas* arranged in a setting of Ferns and *Gypsophila*, with *Kochia scoparia*, *Eulalia zebrina* and *Isolepis gracilis* interspersed. The *Dahlias* included varieties of the large decorative type, both single and double-flowered, and a selection of the Cactus-flowered type in most of the best and newest varieties. (Silver Flora Medal.)

A hands-me group of *Gladioli* was shown by Messrs. KELWAY & SON, Langport, Somerset. The varieties were very numerous, and embraced flowers of almost all shades of colours. (Silver-Gilt Banksian Medal.)

A group of ornamental foliage plants of stove and greenhouse varieties was shown by Messrs. W. BELL & SONS, King's Road, Chelsea, London. Arranged in the centre of the exhibit were several plants in flower of hybrids

between *Cattleya velutina* and *C. aurea*. Amongst the foliage plants were finely-coloured specimens of *Codiaeum Reidii* and *Warrenii*.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, S.W., displayed *Buddleia variabilis Veitchiana*, *B. v. magnifica*, *Sambucus canadensis*, and *Seneciois elivorum* and *Wilsonianum*. On the table they usually occupy with greenhouse plants, Messrs. VEITCH showed a collection of Chinese Asters and yellow and red-flowered plants of *Celosia plumosa*. (Silver Banksian Medal.)

Sir EDMUND LODER, Bart., Leonardslee, Horsham, Sussex (gr. Mr. W. Cook), showed many interesting plants from the open garden. We noticed the handsome blue-flowered *Genetiana asclepiadea*, *Magnolia glauca* (in flower), *Astilbe Davidiana*, *Clematis coccinea*, *Myrtis communis* (finely flowered), *Solanum jasminoides*, *Clethra acuminata*, and *Pelargonium Endlicherianum*. (Bronze Flora Medal.)

by Messrs. J. R. PEARSON & SONS, Lowdham, Notts. It was labelled Mrs. Littleton Dewhurst. Messrs. EGGETT & SON, Portsmouth Road, Thames Ditton, showed a few varieties of hardy Ferns.

AWARDS OF MERIT.

Thalictrum dipterocarpum.—A Chinese species collected by Wilson at elevations of 4,000 to 5,000 feet in Western China. The foliage is like that of *T. angustifolium*, and is glaucous green in colour. The inflorescences form loose panicles about 9 to 10 inches long, with mauve or lilac-coloured flowers. The stamens are pale yellow. Shown by Messrs. JAMES VEITCH & SONS.

Pink Princess Christian.—Of the perpetual-flowering type; a tree-blooming variety, with flowers of moderate size, prettily coloured and laced with a velvety claret shade. Shown by Mr. B. LADHAM, Shirley, Southampton.

Cattleya Gaskello-costaricensis and *Sophro-lachlo Cattleya punicea* (*L. pumila* × *S. c. eximia*), and the white-flowered *Neobenthamia gracilis*.

H. S. GOODSON, Esq., Putney (gr. Mr. G. E. Day), was awarded a Silver Flora Medal for a group, in the centre of which was a fine variety of *Odontioda Charlesworthii*. The exhibit also contained the white *Brasso-Cattleya "Queen Alexandra"*, *Cattleya Tritiana*, the finely-formed *Cypripedium* H. S. Goodson, C. Maudslayi, C. A. de Laresse with two flower-spikes, and *Lachlo-Cattleyas*, of which the showy *L. C. Massangeana* var. Harry Goodson was the best.

Messrs. CHARLESWORTH & Co., Heatn, Bradford, secured a Silver Flora Medal for a select group, the best novelty in which was the new *Sophro-Lachlo-Cattleya Marathon* (see Awards). Others noted were the scarlet *Odontioda*

FIG. 60.—"FOUNTAIN WALK" IN GENERAL SIR DIGHTON PROBYN'S GARDEN AT WINDSOR.

Messrs. THOS. S. WARE, LTD., Feltham, showed seasonable hardy flowers, including *Lathyrus latifolius* The Pearl (a fine white-flowered variety), *Chrysanthemum maximum*, perennial *Phloxes*, *Gaillardias*, *Helenium autumnale*, *Convolvulus mauritanicus*, *Callirhoe involucrata*, and *Becconia cordata*. Messrs. WARE also displayed an assortment of Alpine plants in flower. (Silver Banksian Medal.)

Mr. F. EAMES, Frome, Somerset, showed a large selection of varieties of *Phlox decussata*, especially fine being the white-flowered *Ecklaireux*. (Silver Banksian Medal.)

Several seedling Carnations were shown by Lady FLORENCE DUNCOMBE, Calwich Abbey, Ashbourne (gr. Mr. J. Allen).

Messrs. MOORE, LTD., Rawdon, Leeds, showed flowering spikes of *Lilium nepalense*. A white-flowered sport from Lady Gay Rose was shown

Orchid Committee.

Present: J. Gurney Fowler (in the Chair), and Messrs. Jas. O'Brien (hon. sec.), De B. Crawshaw, Stuart Low, Harry J. Veitch, W. Boxall, F. Sander, A. A. McBean, J. Forster Atcock, W. Cobb, J. Charlesworth, A. Dye, W. P. Bound, H. G. Alexander, H. A. Tracy, W. H. White, Gurney Wilson, and F. J. Hanbury.

Interesting and new plants were very numerous, as will be seen by the number of awards granted.

Sir TREVOR LAWRENCE, Bart., K.C.V.O. (gr. Mr. W. H. White), was awarded a Silver Flora Medal for an interesting group, composed principally of new and rare species, some of which are described under Awards. The others included a fine white form of *Catasetum pileatum* (Hungerthou), *Eulophia Guineensis*, the white and fragrant *Schlimia trifida*, the hybrids *Epi-*

Craveniana, *Cattleya Germania magnifica*, *C. Iris*, *C. Wavriniana*, *Odontoglossum Rolletii*, *O. Lambauiana*, *O. ardentissimum*, and other hybrids, *Lachlo-Cattleyas*, *Cypripediums*, and the beautiful *Zygopetalum Koeblingianum*.

Messrs. GURNEY WILSON & Co., Haywards Heath, were awarded a Silver Flora Medal for a group composed principally of varieties of *Miltoma vexillaria*, the one labelled *leuco-centrum* having a clear, lemon-yellow disc to the lip; the variety *leucochilum* has an entirely white labellum.

DE B. CRAWSHAW, Esq., Rosefield, Scenouks (gr. Mr. Stables), showed a very interesting selection of hybrid *Odontoglossums*, and cut spikes of *O. cristatum*. The most remarkable was *O. Zenobia* (Halls × Edwardii). Other new hybrids were *O. Zena* (scytrum × Harryannum) and *O. Wardii* (Kecklam ×

[Photographed by special permission.]

(Harryanum), both with distinct features. (Silver Banksian Medal.)

Messrs. SANDER & SOSS, St. Albans, showed a group of choice *Odontoglossums*, including the pretty *O. Elaine* (rosulatum × *Harryanum*), good forms of *O. Rolleeae*, and of their fine type *O. crispum*-*Harryanum* Brugense.

Messrs. MOORE, LTD., Rawdon, Leeds, sent a group in which were plants of *Vanda coccinea*, *Oncidium lanceanum*, *Bulbophyllum Godsalmanii*, *Scutellaria Hadwenti*, *Angraecum bilobum*, and a very pretty little *Liparis* with a scarlet lip. (Silver Banksian Medal.)

Messrs. HUGH LOW & CO., Clapton, showed good examples of *Oncidium lanceanum*, *O. oblongatum*, *Scutellaria Hadwenti*, *Bulbophyllum papillosum*, *B. Lobbianum*, *Ancistrorchilus Thomsponianum*, *Selenipedium macrochilum*, and *Cypripediums*. (Silver Banksian Medal.)

LT.-COL. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. C. Alexander), showed *Brassica-Cattleya*, *Dischandra-Warneri*, *Westonbirt* variety, a large silver-white flower tinged with rose-lilac; *Cattleya Tacitus* (blue-rose × *Germania superba*), *C. Euphratica*, "Westonbirt variety" (*Worcesterii* × *superba*), and others (see Awards).

Messrs. STANLEY & CO., Southgate, sent examples of *Cypripedium A. de Lairese* and *Laelio-Cattleya elegans* Turneri.

Mrs. T. B. HAYWOOD, Regate, showed *Cypripedium Sanderianum*-Curtisii.

C. W. JESSOP, Esq., Cliff Cottage, Rawdon (gr. Mr. Wilkinson), displayed a well-cultivated plant of the bright yellow-flowered *Satyrion coriifolium*.

W. WATERS BUTLER, Esq., Southfield, Edgbaston, Birmingham, sent *Odontoglossum Uro-Skinneri*, *Southfield* variety, with large and handsome flowers.

FIRST-CLASS CERTIFICATE.

Odontoglossum Wiganianum superbum (*Wilckeanum* × *Rolleeae*), from Sir TREVOR LAWRENCE, Bart., K.C.V.O. (gr. Mr. W. H. White). The largest and most beautiful form of this fine hybrid. The finely-formed flower has sepals and petals of a citron-yellow colour marked with purple. The lip is broad, white, marked with rose-purple.

AWARDS OF MERIT.

Sophro-Laelio-Cattleya Mada vinicolor (*S.-L. Ieta Orpeltiana* × *C. bicolor*), from LT.-COL. G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. C. Alexander). A remarkable colour variation in the hybrid for which an Award of Merit was given at the meeting on October 29, 1907. The flower of the variety under notice is as large as that of *C. bicolor*; the sepals and petals are vinous purple, the lip of deep claret colour, and the *Bezy-colium* bluish-white.

Cypripedium Rosellii (*vincine Sanderi* × *Maudslayi*), from LT.-COL. G. L. HOLFORD. A finely-formed hybrid coloured similar to *C. insignis* Sanderi. The upper sepal is circular, and in colour yellow with emerald green lines and a broad white upper part; the rest of the flower is yellow, tinged with green.

Sophro-Laelio-Cattleya Marathon (*Sophro-Laelia Pycnela* × *Cattleya Empusa Fendrickii*), from Messrs. CHARLESWORTH & CO., Heaton, Bradford. A fine hybrid of the shape and size of a *Cattleya* flower. The sepals and petals are silvery white, flaked with rose. The lip is deep ruby red with an orange-coloured glow, the base being white with rose markings.

Trichopilia (Pitumna) nivalis alba, from Messrs. CHARLESWORTH & CO. A pure white form without the yellow eye seen in the type.

Odontoglossum Zornbia (*Hallii* × *Edwardsii*), from DE B. CRAWFORD, Esq., Rosefield, Sevenoaks (gr. Mr. Stables). A remarkable hybrid of the habit of *O. Thompsonianum*, but white in colour, the sepals and petals being of a dark chocolate-purple, tipped with white; the lip is coloured chestnut-red, with a whitish apex and light markings around the curiously-formed crest.

BOTANICAL CERTIFICATE.

Catantus latibulum.—A green flower of globular form, with the front portion of the lip projected.

Catantus Clavatum.—The flowers are produced on an erect spike; they are pale green in colour, with fringed sides to the lip.

Trostachya Kindianum.—A dwarf species, with racemes of small, star-shaped, yellowish flowers.

Epidendrum Lombocanum.—A dwarf, tufted plant of the *Nanades* section, bearing profusely pretty flowers with whitish sepals and large, fleshy, claret-coloured labellums.

Eria longispicata.—A plant of *Erides*-like growth, producing long, erect spikes of small, whitish flowers marked with purple.

Polystachya flavescens.—A remarkable plant in its genus, a native of Central Africa, the inflorescence resembling a flower-spike of *Neobenthama*. The plant is about 1 foot in height, in growth resembling a small, slender specimen of *Ansellia*; the pseudo-bulbs are tapering and compressed, and bear a slender scape 1 foot high, terminated by a bunch of pure white flowers, with purple markings on the lip. The Botanical Certificates were all granted to Sir TREVOR LAWRENCE, Bart.

CULTURAL COMMENTARIES.

To Mr. W. H. White, Orchard grower to Sir TREVOR LAWRENCE, Bart., K.C.V.O., for two specimens of the graceful *Odontoglossum aspidanthium*, each with about 15 flower-spikes.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (in the Chair); and Messrs. Jos. Cheal, Alex. Dean, J. Willard, H. Parr, Joseph Davis, Chas. Foster, Geo. Reynolds, H. Markham, Geo. Wythes, Owen Thomas, H. Somers Rivers, A. H. Pearson, and James Vert.

Reference was made to the death of Alderman Balderson, a former vice-president of the Committee. A vote of sympathy with deceased's family was expressed and recorded in the minute book.

Messrs. PAUL & SONS, Waltham Cross, Herts., showed a group of fruit trees in pots, including Plums, Pears, and Nectarines. The Plums were very freely fruited, varieties such as Pond's Seedling, Grand Duke, Belle de Septembre and White Magnum Bonum having excellent crops. The Pear trees were shapely specimens, and, though small, were freely fruited, Brockworth Park, Beurre Bacheler, Marie Louise d'Uccle, and Dejeant Bonissac representing a selection of the varieties shown. (Silver Knightian Medal.)

Messrs. S. SPOONER & SONS, Hounslow, Middlesex, showed a collection of Apples, Pears, and a few Plums. There were good samples of Beauty of Bath, Lady Sudeley, Stirling Castle, Grenadier, Cardinal, Ecklinville Seedling and other varieties of Apples; Early Transparent and The Czar Plums were also fine. The Pears were very immature. (Silver Banksian Medal.) A few baskets of early dessert Apples were shown by Messrs. JAS. YERREN & SONS, Chelsea; and Messrs. HUGH LOW & CO., Bush Hill Park, Enfield.

AWARD OF MERIT.

Apple Feltham Beauty.—An early dessert fruit raised from Cox's Orange Pippin × Gladstone. The fruit is of medium size, flattish-round in shape and brightly coloured, especially at the stalk end. The ground colour is yellowish-green, but this is marked very heavily with red, sometimes in streaks. The eye is closed and set in a shallow basin. The stalk is slender, about 1-inch in length, and also set in a shallow cavity. The flesh is brisk and sweet. The variety forms a valuable addition to the list of early dessert Apples. Shown by Messrs. JAS. YERREN & SONS.

FLORAL COMMITTEE AT WISLEY.

AUGUST 11. A deputation from the Floral Committee visited the gardens at Wisley on the above date. There were present W. Marshall (Chairman), and George Paul, W. Bain, George Gordon, Charles Dixon, and R. Hoop, F.R.S.E.

An inspection was made of the *Canas* cultivated out-of-doors. The trial is a comprehensive one, and the plants have succeeded well, but the hot weather and high winds that occurred shortly before the inspection caused the flowers to be in less perfect condition than they would otherwise have been. It was decided that a further inspection would be necessary in the

course of a fortnight, and in the meantime three marks were awarded to each of the following varieties. These marks, it may be pointed out, were awarded after judging the plants from the point of view of outdoor cultivation.

Canas Forest Wood.—This variety has a dwarf habit, is free in flowering, and has rich, rosy-crimson flowers.

C. Mictore.—The flowers of this variety are a very attractive shade of orange-red, being deeper than apricot, but of the same tone.

C. L. E. Bailey.—This variety was given an Award of Merit in 1894, and being now judged to be of first-rate quality for out-of-door cultivation, was given three marks. The flowers are yellow, with pale-reddish spots.

C. Elizabeth Hoss.—This, like the preceding variety, is yellow, spotted with red, but in this case the spotting is of a deeper tint.

C. Dr. Marcus.—This variety has reddish foliage, and exceedingly rich, rosy-tinted flowers, combined with a good habit of growth.

C. William Saunders.—Reddish foliage also distinguishes this variety. The flowers are of a shade of rosy-crimson, but are distinct from those of *Dr. Marcus*.

An inspection was made of the herbaceous *Phlox*, which will be visited again later. Three marks were recommended to each of the following varieties:—

Phlox Saxatilis.—This is a fine, rosy-purple variety of suitable height for the flower border.

P. Jules Cambon.—A purple-flowered variety with white centre.

P. Siebold.—A first-rate, bright-reddish, almost scarlet variety.

P. Andre Michaux.—A very dwarf variety, with large, beautiful, pink flowers, the shade being somewhat varied.

P. General Giovannielli.—An excellent variety with red flowers.

P. Lady Tawdall.—Judging from the specimens seen, this exceedingly dwarf *Phlox* is superior to any existing white variety, the inflorescences being unusually large, and the individual flowers also.

In addition to the above-mentioned varieties, one named *Obergartner Mack* had magnificent flowers of a shade of pink, such as is seen in *Zonal Pelargonium*, but as the flowers burn in sunshine no marks were awarded. The variety, however, might be valuable if cultivated in comparative shade.

DUTCH BULB GROWERS'.

The following awards have been made in recent meetings of the Floral Committee at Haarlem:—

FIRST-CLASS CERTIFICATES.

Early Gladiolus Gordon.—Lilac, with white blotch.

Early Gladiolus Innovation.—Light rose, with white blotches.

Iris hispanica Flora.—White, shaded with lilac.

Iris hispanica Queen Wilhelmina.—Pure white and deep yellow; a variety remarkably early in flowering.

Ixia Lady Helen Vincent.—The colour is soft, rosy pink; a new shade of colour in *Ixia*.

Richardia Gloire de Hollande.—The colour is canary yellow, with a deep purple basal blotch; the foliage is mottled with white.

Richardia Mrs. Roosevelt.—Light sulphur yellow; a variety of American origin.

AWARDS OF MERIT.

Anemone cruenta alba.—A pure white seedling of this lovely biennial plant. It flowered for the first time in 1900, and has not yet been introduced into commerce.

Anemone Comtesse de Ruille.—A double variety of good form; the colour is double violet.

Anemone White Lady.—A fine double white variety.

Early Gladiolus Catharina.—White, with light-coloured blotches.

Early Gladiolus Lady Howard.—White, shaded with soft lilac.

Iris hispanica Lethain.—Light blue and soft lilac.

Lilium bulbiferum ("The Sultan").—The colour of the flower is brownish-red.

SHROPSHIRE HORTICULTURAL.

Exhibition at Shrewsbury, August 19 and 20.

ON Wednesday last the Shropshire Horticultural Society held its thirty-fourth annual autumn exhibition in the Quarry Grounds, Shrewsbury, and it remained open until Thursday night. The weather on Wednesday was dry, but clouds hung over the town and obscured the sun, which shone brightly enough in some of the counties crossed in the return journey to London. The attendance of visitors appeared very large, but many were thankful that the discomforts experienced in the crowded tents on some previous occasions when hot sunshine prevailed were not suffered.

The show was quite as good as previous displays have been, and in some respects, at least, the interest has increased. This was particularly the case in the fruit section, where the Champion fruit class, consisting of 30 dishes of fruit, claimed more than the interest that was hitherto centred in the Champion Grape class. There is little doubt but the committee did right in arranging for this competition when the cup offered for Grapes alone was won outright last year by Lord Hastings and his skilful fruit grower, Mr. Shingler. The class is one of an exacting nature, for the resources of an establishment must be considerable before any aspiration can be indulged that a creditable collection can be obtained from it which will comply with the terms of the schedule. That five collections were staged is, therefore, satisfactory, and it is, even more satisfactory that the exhibit which gained the 1st prize was of such unusually good quality as the produce shown by Mr. Barnes from the Duke of WESTMINSTER'S garden. But we think that the Committee will do well on a future occasion to require that the number of fruits forming a dish shall be the same in each collection. It is difficult to believe that an exhibitor who limits his dishes of Peaches to Apples to six, or to Apples to one, perfect equality with another who shows 12 fruits of each, and consequently produces a "show" that may, at the very least, cause the work of adjudication to be attended with greater difficulty, even if it has not an effect in influencing the judges' decision.

Grapes were not so good as they have been many times at Shrewsbury, and the absence of an exhibit from Mr. Shingler was partly responsible for this.

The groups and specimen plants were excellent, and Messrs. CYRUS were again very successful in the classes for these plants.

Cut flowers of choice sorts were abundant, and they were the produce of excellent cultivation.

It seems needless to praise the vegetables that at Shrewsbury are so admirable each year, apparently uninfluenced by the character of the particular season, but we may mention that Mr. ERWIN BECKETT, who is at present contributing to the weekly *Calendar* in the "Kitchen Garden," obtained remarkable success, winning 1st prizes in three of the most important classes.

Messrs. Adnitt and Naunton, the indefatigable honorary secretaries, were again at the helm, and the arrangements, therefore, worked as smoothly as heretofore.

The receipts on Wednesday amounted to £1,221, being £18 in excess of any previous first day at these exhibitions.

CHAMPION FRUIT DISPLAY.

The Champion Grape class established in 1861 came to a termination last year, when Lord HASTINGS (Mr. Shingler) won the fifty-guinea cup for the third time, upon which that valuable prize became the absolute property of the exhibitor. In place of that competition, which undoubtedly did much to maintain very great interest in the Shrewsbury Shows, the Committee instituted this fruit class, in which the following prizes were offered:—1st prize, a Champion Silver Cup, valued at 25 guineas, and a sum of £20; 2nd prize, Gold Medal and £17 10s.; 3rd prize, Silver-Gilt Medal and £15; 4th prize, £10; 5th prize, £8; and 6th prize, £5. Each collection consisted of 30 dishes of ripe fruit in not fewer than 10 distinct kinds, and was arranged in a space not exceeding 12 feet by 4 feet 6 inches. Not more than four varieties of one kind, nor

more than two dishes of one variety, could be shown in a single exhibit. Only one variety was to be shown on one dish, and the total number was not to exceed 30 dishes.

Each collection might be decorated with flowering and foliage plants in pots not exceeding 5 inches in diameter, also cut flowers and foliage (including Orchids), shown in glassware, baskets or loose, at exhibitor's discretion; a maximum number of plants was previously agreed upon for each kind of fruit. Black and white Grapes were considered distinct kinds of fruit, and two bunches of each kind formed a dish. This being a "decorated fruit display" class, the decorations were not judged separately, but the points thus gained were added to those awarded for the quality of fruit. The maximum points awarded for decoration were as follows:—

Beauty of flower and foliage	... 8 points
Harmonious blending of colours	... 8 "
General arrangement for effect	... 8 "

The Champion or Challenge Cup will become the property of any competitor who wins it three times, not necessarily in succession.

There were five exhibits staged, and the judging took considerable time, being the whole work apportioned to two judges, namely, Mr. A. McKellar and Mr. Peter Blair. The 1st prize was won by the Duke of WESTMINSTER, Eaton Hall, Chester (gr. Mr. N. F. Barnes). He had the following varieties of Grape: Appley Towers (four bunches), Muscat of Alexandria (four bunches), Madresfield Court (four bunches). The Apples were remarkable both for colour and size, the varieties being Emperor Alexander, Washington, Cox's Orange Pippin (we have never seen this variety more highly coloured), and James Grieve. Peaches were of extraordinary size, and included Barrington (two dishes), Princess of Wales, and Royal George. Nectarines included the varieties Pineapple (two dishes), Humboldt, and Elrige. Other dishes were Plum, Jefferson's, Apricot, Moor Park, Fig, Brown Turkey and Branswick; Pears Souvenir du Congrès, Triomphe de Vienne, and Marguerite Marillat. There were four Melons. The 2nd prize was awarded to the Earl of HARRINGTON, Elvaston Castle, Derby (gr. Mr. J. H. Goodacre), who had in the centre of his exhibit a marvellous dish of ten fruits of Emperor Alexander Apple. Other dishes of extraordinary quality were Pineapple Nectarine, Triomphe de Vienne Peach, Thames Bank Peach, Negro Largo Fig, and Golden Transparent Gage Plums. The Melons were very fine in appearance, and the Grapes (including 26 bunches) of medium good quality throughout. 3rd, GEORGE FARQUHARSON, Esq., Ledbury (gr. Mr. Geo. Mullins). 4th, the Duke of PORTLAND, Welbeck Abbey, Notts (gr. Mr. J. Gibson). 5th, E. H. Wood, Esq., Temple Newsam, near Leeds (gr. Mr. R. Dawes).

COLLECTIONS OF FRUIT.

Twelve dishes.—In this class no fewer than nine kinds, and not more than two varieties of a kind, are allowed. Black and white Grapes are considered distinct kinds of fruits. Pineapples are excluded. The 1st prize was gained by the Rt. Hon. Lord BELPER, Kingston Hall, Derby (gr. Mr. W. H. Cooke). This exhibitor staged good bunches of Madresfield Court Grapes and equally good Black Alicante Grapes; the Muscat of Alexandria bunches were scarcely finished as they should be. He had excellent Apples in Peasgood's Nonsuch and Emperor Alexander, also Peaches Barrington and Sea Eagle, Nectarine Pineapple, Plum Magnum Bonum, Pear Duchesse d'Angoulême, Fig Brown Turkey and Melon Hero of Lockinge. The 2nd prize was awarded to Lady ASHBURTON, Melchet Court, Weymouth (gr. Mr. G. Hain), who had excellent Branswick Figs, Pineapple Nectarines, Sea Eagle Peaches, and other dishes of good quality. 3rd, Mr. F. NEED, Malvern, with a very creditable collection, in which the stone fruits were very highly coloured. This exhibitor was awarded the 1st prize for the decorations employed, the 2nd prize being awarded to Lord BELPER, and the 3rd to Lady ASHBURTON.

Nine dishes.—There were six collections shown

in this class, and the 1st prize was won by C. F. K. MAIWARING, Esq., Ellesmere (gr. Mr. H. Stowe). This exhibitor showed Muscat of Alexandria and Madresfield Court Grapes, moderate-sized bunches with well-coloured berries; Diamond Peach, Dryden Nectarine, Branswick Fig, Transparent Gage Plum, Moor Park Apricot, Beauty of Bath Apple, and a seedling Melon. The quality generally was good without being higher than usual exhibition standard, and all the fruits were of medium size. This exhibit was also awarded the 1st prize for the decorations employed, the scheme consisting of *Gloriosa superba*, *Gypsophila* flowers, and sprays of *Asparagus* and *Sclagella*. The 2nd prize for fruit was awarded to Mrs. SWANN, Hailston Hall (gr. Mr. C. Roberts), whose Lady Sudeley Apples and Royal Peach Apprets were very fine. This exhibitor obtained the 3rd prize for decorations. The 3rd prize for fruit was gained by Lord FRETHER, Brynkaul, Chirk (gr. Mr. W. Dawes). The Grapes in this case were much heavier, the varieties being the same as shown in the 1st prize collection, but the bunches much larger and the berries scarcely so well finished. Capt. HEYWOOD-LOXSDALE, Shavington Hall, near Shrewsbury (gr. Mr. J. Mills), was awarded the 4th prize for fruit, and the 2nd prize for the decorations.

GRAPES.

Twelve bunches in four or more distinct varieties, but not more than four bunches of any one variety.—The conditions of this competition were similar to those in the Champion Grape class of last year, but in place of the more expensive Challenge Cup the 1st prize on this occasion consisted of a Silver Cup valued at £10 and a sum of £20; the 2nd prize was £16; the 3rd prize £12; the 4th prize £9; the 5th prize £6; and the 6th prize £4. Each bunch was judged on its individual merits and points awarded accordingly. The bunches were arranged on boards, and each exhibit had a space of 8 feet 6 inches; the boards being in two tiers 2 feet 3 inches wide. The judges were instructed to regard superior cultivation and finish as of the highest importance. Each exhibit had to be decorated, but the decorations were judged separately and prizes for these were awarded as follows: 1st prize, £2; 2nd prize, £1 10s.; 3rd prize, £1.

This season there were only four exhibits in this class, and the 1st prize was won by the Earl of HARRINGTON, Elvaston Castle, Derbyshire (gr. Mr. J. H. Goodacre). His varieties were as follows, and the points awarded are appended in table:—

	Possible No. of Points.	Points Awarded.
Black Hamburg (1) 10	8
Muscat Hamburg (2) 10	8
Muscat of Alexandria (3) 11	9
Madresfield Court (4) 10	9
Muscat of Alexandria (5) 11	9½
Madresfield Court (6) 10	8
Madresfield Court (7) 10	8½
Muscat of Alexandria (8) 11	10
Muscat Hamburg (9) 10	8
Madresfield Court (10) 10	9
Madresfield Court (11) 10	9
Muscat of Alexandria (12) 11	10
Total 124	107

The 2nd prize was awarded to GRANVILLE FORTHARSON, Esq., Easton Court (gr. Mr. G. Mullins), who obtained 97½ points out of a possible number of 123. 3rd, G. A. BRIS, Esq., M.P., Tyntesfield, Flax Bourton, Glos. (gr. Mr. T. Wilkinson), who obtained 96½ points, being only one point below the 2nd prize exhibit. 4th, Rt. Hon. Lord BELPER, Kingston Hall, Derby (gr. Mr. W. H. Cooke), who had 93 points.

The prizes for decorations were awarded as follows: 1st, GRANT FORTHARSON, Esq.; 2nd, Rt. Hon. Lord BELPER; 3rd, the Earl of HARRINGTON.

Four bunches, including one white and one black variety.—There were four exhibits in this class,

the best being one from Lord HARLECH, Brogyvaun, Oswestry (gr. Mr. T. Lambert). His Madresfield Court was almost perfect bunches in form and in finish of berries, the bloom being remarkable, but many of the berries were much below what is desirable. In the other case, that of Muscat of Alexandria, the bunches were very long, somewhat irregular in outline, and uneven in size of berries. They were scarcely fully ripened. The 2nd prize was gained by C. G. A. SMITH, Esq., Vaynor Park, Bangor (gr. Mr. H. Weaver), who showed Black Hamburgh (very fine and beautifully finished) and Muscat of Alexandria. The same varieties were shown by H. ST. MAUR, Esq., Newton Abbot (gr. Mr. G. Richardson), who had 3rd prize.

Black Hamburgh.—There were 12 exhibits in the Black Hamburgh class, and the 1st prize was gained by two first-class bunches shown by J. BRINTON, Esq., Moor Hall, Stourport (gr. Mr. H. Wilson), and E. A. YOUNG, Esq., Bangor (gr. Mr. A. Ruddock), the 3rd prize.

There were 18 exhibits in a class for a single bunch of the same variety. H. ST. MAUR, Esq., gained the 1st prize for a heavy, well-shouldered bunch of perfectly-ripened and well-bloomed berries. 2nd, G. A. GIBBS, Esq., Bourton, Salop.

Black Muscat varieties.—In a class for the best two bunches of Black Grapes (Muscat varieties) there were seven exhibits. The 1st prize was awarded to two long, splendidly coloured of the variety Mrs. Pine, shown by Sir D. D. KING, Bart., Exeter (gr. Mr. S. J. Baker), 2nd, Madresfield Court, shown by Sir W. COOKE, Bart., Ledbury (gr. Mr. H. Butcher), and 3rd, Muscat Hamburgh, shown by the Earl of HARRINGTON, Elvaston Castle, Derbyshire (gr. Mr. H. Goodacre).

Muscat variety.—Seven exhibits in the Muscat of Alexandria class were shown, of these the best was one from Col. F. HAYHURST, Middlewich (gr. Mr. G. H. Hall), who had two beautiful bunches with excellent, highly-coloured berries. 2nd, G. A. GIBBS, Esq., M.P., Bourton (gr. Mr. J. Wilkinson), and 3rd, J. BRINTON, Esq., Moor Hall, Stourport.

Black Alicante.—Five pairs of bunches were staged in this class, the best being from Mrs. F. NEED, Malvern (gr. Mr. J. Jones); 2nd, Col. F. HAYHURST, Middlewich (gr. Mr. G. H. Hall); and 3rd, H. ST. MAUR, Esq., Newton Abbot.

Any other Black Grapes.—Of five exhibits in this class the best was one of Gros Maroc shown by G. FARQUHARSON, Esq., Ledbury (gr. Mr. G. Mullins). The 2nd prize was awarded to a very large, almost round Grape named Black Duke, shown by Col. F. HAYHURST, 3rd, Gros Maroc, shown by Mrs. F. NEED, Malvern (gr. Mr. J. Jones).
White Muscat.—In a class for two bunches of White Muscat Grapes there were 12 exhibits. The 1st prize was won by the Earl of HARRINGTON, the award having been evidently given for better finish, but these were not first-class exhibition bunches from the point of view of size. 2nd, Col. F. HAYHURST, and 3rd, H. ST. MAUR, Esq. The single-dish class for White Muscats was won by G. A. GIBBS, Esq., M.P., and the Earl of HARRINGTON had the 2nd prize.

Vital classes.—In the classes for Grapes reserved for cultivators in the county of Salop the 1st prize for White Grapes was won by H. A. ATENBOROUGH, Esq., Daventry, for Black Hamburgh by Lord HARLECH; for Madresfield Court by Capt. H. LONSDALE; that for two bunches of Black Grapes by the Rev. T. M. BULLKLEY OWEN, West Felton (gr. Mr. J. Langley); for two bunches of White Muscats by Lord TREVOR; for two bunches of White Grapes by Capt. H. LONSDALE, for Black Grapes by Mr. H. TERNER, Wellington, and that for two bunches of White Grapes by E. C. BEELE, Esq., Cyngelede, Shrewsbury (gr. Mr. E. Clowes).

OTHER KINDS OF FRUIT.

Melons.—In all there were 44 Melons shown in the four classes allotted for varieties of this fruit. The best white-fleshed variety was SUTTON'S Royal Favourite, shown by W. L. LOVATT, Esq., Wellington (gr. Mr. J. Cook), the best scarlet-fleshed variety an unnamed seedling shown by R. LL. KENYON, Esq. (gr. Mr. J. Durnett), and the best green-fleshed variety, Early Favourite, also shown by R. LL. KENYON, Esq.

Apricots.—There were six dishes of Apricots, the 1st prize being given for very large, handsome fruits of an unnamed variety shown by Major A. O. LLOYD, Seaton Knolls (gr. Mr. H. G. Trichard). 2nd, the Marquis of NORTHAMPTON (gr. Mr. Searle), who showed the variety Moor Park.

Nectarines.—Of seven dishes of Nectarines the best was Pineapple, shown by Lady ASHBURTON, Romney, Hants (gr. Mr. G. Hall). 2nd, Early Rivers, shown by Mr. W. PALMER, Andover, and 3rd, Pineapple from F. J. MYERS, Esq., Banbury (gr. Mr. Bush).

Peaches.—There were 11 dishes of Peaches, and the 1st prize was awarded to Bellegarde, shown by Major A. O. LLOYD; the 2nd prize to the variety Exquisite, shown by the Earl of CARLISLE, Welburn (gr. Mr. A. E. Sutton), and 3rd prize, Golden Eagle, from H. ST. MAUR, Esq.

Cherries.—There were only eight dishes of Cherries in the single-dish class, but excellent fruits of Antigarrig Apple, the 1st prize for Gage's variety, FARQUHARSON, Esq., Ledbury.

Plums.—There were four dishes shown in the class for red or purple Plums, and three dishes in that for yellow Plums, and three also in the class for Gage Plums. In this last-mentioned class the 1st prize was awarded to extra fine fruits of Oullin's Golden Gage, shown by the Marquis of NORTHAMPTON.

Six dishes of hardy fruits.—A class for six dishes of hardy fruits was reserved for cultivators in the county of Salop. The 1st prize was won by T. A. M. DICKINSON, Esq., Eppington House, Shrewsbury (gr. Mr. G. Gilbert), the 2nd prize by Mrs. F. ALDERSON, Frankton. The fruits included Black and Red Currants, Gooseberries, Cherries, Apples, &c.

GROUPS OF MISCELLANEOUS PLANTS.

The competition in classes 5 and 6 was decidedly keen, and the materials used in most of the groups was both choice and well grown. The judges were "instructed to regard an original and artistic arrangement a great feature" in the groups, but the method of arrangement in most instances did not differ greatly from that generally employed in groups of this description. One exhibitor, however, adopted a somewhat less stereotyped method in setting up his group, viz., G. H. KENDRICK, Esq., and in each case the effect was pleasing and effective, but not sufficiently so to compensate for the high quality and superior culture combined with the good arrangement of the higher placed exhibits. Class 5 was for a group of miscellaneous plants, in and out of bloom, arranged to produce the best effect and occupying a space of 25 square feet. In this, the premier plant class, Messrs. CYPHER & SONS, of Cheltenham, were placed first for a lightly arranged group, which included many choice and well-grown plants, including Orchids. Among the most conspicuous Orchids were *Laelio-Cattleya Canhamiana*, *Dendrobium Phalenopsis*, *Vanda cœrulea*, *Odonoglossum crispum*, *Oncidium Marshallianum*, &c. The background consisted of a fine specimen of *Kentia Forsteriana* supported by some well-coloured *Crotons* and *Lilium speciosum*.

The pretty little scarlet *Fuchsia triphylla* was very effectively employed among dark-foliaged plants and moss on the floor in the immediate foreground. The 2nd prize in this class went to Mr. W. A. HOLMES, Chesterfield. Here again the plants showed good culture and quality, but the exhibit was perhaps too crowded and the plants in the foreground too tall; nevertheless, the general effect was pleasing. Some of the most conspicuous plants were *Croton Thompsonii*, *caudatus*, and *Evansii*; *Odonoglossum crispum* and *Cattleya Harrisoniana* were also freely used.

The 3rd prize was deservedly awarded to G. H. KENDRICK, Esq., Edgbaston (gr. Mr. J. V. MacDonald). As stated above, the method of arrangement certainly showed an improvement upon the style usually adopted. Here again full use was made of *Fuchsia triphylla* in the background, combined with *Lilium speciosum* and surmounted by a fine *Phoenix*. There were some good plants of *Crotons Thompsonii*, *Warrenii*, and *Emper Alexander*.

Group of ornamental foliaged plants, Palms, Ferns, &c.—Messrs. CYPHER & SONS also won the 1st prize in this class with exceedingly well-grown plants, effectively arranged. The outstanding features included a good *Kentia* in the background and some very fine specimens of *Croton*,

Warrenii, *caudatus*, *tortilis*, *Flamingo*, *Aigburth Gem*, &c., and the groundwork was lightly filled in with a great wealth of well-cultivated smaller plants. G. H. KENDRICK, Esq., took the 2nd prize with an exceedingly well-arranged group, each plant standing out well and showing its full value, but the plants lacked quality as compared with the 1st prize group. The 3rd prize was awarded to Mr. W. A. HOLMES, Chesterfield, for a good group, which included a very fine *Kentia*, some good plants of *Acalypha hispida*, and *Crotons Princess of Wales* and *Lady Zeland*.

GROUP OF TUBEROUS BEGONIAS.

This class usually produces keen competition. In this instance Messrs. WAKE, LTD., Feltham, were 1st with a splendid exhibit, their flowers showing great range of colour and splendid form. Some of the finest varieties were *Lady Cromer* (delicate pink), *Patrick Anislie* (scarlet), and Mrs. A. BRANDT, 2nd, Messrs. BLACKMORE & LANGTON, Twerton, Avon. Among their best flowers were Mrs. J. Booth, *White Swan*, and Mrs. T. ROSSITER, 3rd, Mr. FRED. DAVIS, Pershore, who had a very fine group, some of the flowers being a little coarse and the centres of blooms too much split up.

SPECIMEN PLANTS.

The principal class provided for these was for 15 plants. The 1st prize of £20 was won by Messrs. JAS. CYPHER & SONS, of Cheltenham, who had huge, well-flowered specimens of *Ixora Duffii*, *Static intermedia*, *S. profusa*, *Rondeletia speciosa major*, and *Erica Eweriana*. *Kentia Belmoreana*, *K. Forsteriana*, and *Thrinax elegans* were shown in splendid condition. 2nd, Mr. W. VAUSE, Leamington Spa, who had good plants of *Clodendron Balfourii*, two *Bougainvilleas*, and two *Staticeas*, &c. 3rd, Mr. W. R. MAXING, Dudley.

For six stove and greenhouse plants Messrs. JAS. CYPHER & SONS were placed 1st with beautiful specimens of *Rondeletia speciosa major*, *Ixora Duffii*, *Static intermedia*, *S. profusa*, *Allamanda nobilis*, and *Chironia ixifera*. The 2nd award fell to Mr. W. VAUSE, whose plants were smaller and his flowers not so well developed.

In a class reserved for six fine foliage plants Mr. W. VAUSE was placed 1st with four well-coloured *Codiaeums* and two tall *Kentias*, one of which had a number of very rusty leaflets at the edges. 2nd, T. SUTTON TIMMS, Esq., Allerton, Liverpool (gr. Mr. B. Cromwell), whose best plant was *Codiaeum chelsoni*. 3rd, Messrs. JAS. CYPHER & SONS.

The class provided for 30 stove and greenhouse plants, to be grown in 10-inch pots, is always a feature at Shrewsbury, and the specimens with which Messrs. JAS. CYPHER & SONS gained 1st prize were quite up to the quality of previous years. They showed eight *Ixoras*, three *Chironia ixifera*, one *Rondeletia speciosa major*, four *Crotons*, two *Static intermedia*, *Clodendron fallax*, *C. Balfouriana*, *Acalypha hispida*, &c. 2nd, T. SUTTON TIMMS, Esq., Allerton, Liverpool (gr. Mr. B. Cromwell), whose plants were smaller and not so well flowered. 3rd, Mrs. SWANN, Halston Hall (gr. Mr. C. Roberts).

For 12 stove or greenhouse plants, also to be grown in 10-inch pots, Lord HARLECH, Brogyvaun, Oswestry (gr. Mr. T. Lambert) was 1st with shapely plants of *Clodendrons Balfouriana* and *fallax*, *Dipladania amabilis*, *Acalypha hispida*, *Allamanda Williamsii*, &c. 2nd, Sir A. MCNIZ, Bart., M.P., Dunsmore, Rugby (gr. Mr. H. Blakeway), whose best specimens were *Cycas revoluta*, *Chironia ixifera*, and *Rondeletia speciosa*. 3rd, Mr. W. R. MAXING, Dudley.

E. VAUGHTON, Esq., Handsworth (gr. Mr. C. Kelland), had the best four exotic Ferns; and Lord HARLECH (gr. Mr. T. Lambert) staged the winning six varieties of *Dracaenas*. The varieties *Shepherdii* and *Bapustinii* were very good. 2nd, Sir A. MCNIZ, Bart., M.P., Rugby (gr. Mr. H. Blakeway).

T. SUTTON TIMMS, Esq. (gr. Mr. B. Cromwell) was awarded 1st prize in a class for six *Caladiums*, and in another class for 12 table plants. In the last-named class he showed 10 richly-coloured, narrow-leaved *Crotons*, one *Coccos Palm*, and one *Dracaena*.

The best set of four *Fuchsias* and the best six double-flowered *Pelargoniums* were staged by Mrs. M. JOWETT, Hynion, Liverpool (gr. Mr. E. Bridge).

Colonel W. G. PATCHETT, Broome Hall, Shrewsbury (gr. Mr. J. Swain), won the 1st prize in a class for four pyramid-shaped plants of Coleus.

The best half-dozen single-flowered Zonal Pelargoniums came from Mrs. R. TAYLOR, Abbey Foregate (gr. Mr. H. Chife).

Mr. T. HAMMOND won the 1st prize in a class for three double and three single Begonias. 2nd, C. BURK, Esq., Oaklands (gr. Mr. A. Jones). The last-named exhibitor was placed 1st in a class provided for 12 Gloxinias. The plants carried large, shapely, well-coloured flowers.

OPEN ONLY TO EXHIBITORS LIVING IN THE COUNTY OF SALOP.

The principal class was for a group of miscellaneous plants occupying a space of 100 square feet. Of the two exhibits for the first prize of £10, Mrs. SWANN, Halstead Hall (gr. Mr. C. Roberts), was placed first. She had a nice collection of foliage and flowering plants artistically arranged. 2nd, Dr. E. BIRD, Newport House (gr. Mr. T. Edwards).

For six stove and greenhouse plants Lord HARLEIGH (gr. Mr. T. Lambourne) won 1st prize. His best plants were *Eucharis grandiflora*, *Isora Duffii*, and *Clerodendron Balfourii*.

In a similar class to that last-named, G. BERR, Esq., Oaklands (gr. Mr. A. Jones), took the lead, W. L. LOVETT, Esq., Orleton House (gr. Mr. J. Cook) being 2nd. Mr. T. HAMMOND had the best four Begonias (two double and two single-flowered varieties), and W. L. LOVETT, Esq., showed the best dozen plants in pots not exceeding 5 inches inside measurement.

CUT FLOWERS.

BOUQUETS.

The bouquets are always excellent at the Shrewsbury Shows, and on this occasion there were a large number of beautiful arrangements. The 1st prize for a bride's bouquet (with Orchids) and two bridesmaids' bouquets (Orchids excluded) were shown by Messrs. FELTON & SONS, Hanover Square, London. The bride's bouquet was composed chiefly of *Oenothera crispum*, *Phloxenopsis*, white *Cattleyas*, &c., with Asparagus sprays and white ribbons. The bridesmaids' bouquets were alike, each being composed of pink-coloured Carnations. 2nd, Mr. J. E. KNIGHT, Wolverhampton; and 3rd, Messrs. BOTTOMLEY & BERTON, Elland, Yorks.

In a separate class for the best bride's bouquet Mr. W. H. GARNER, Altrincham, obtained the 1st prize, and in the following class for a hand bouquet he also won the highest award. The next class was for a hand bouquet (Orchids excluded), and Messrs. FELTON & SONS won the 1st prize. Mr. W. TRESSEDER, Cardiff, was awarded the 1st prize for a bouquet of Dahlias, and Sir A. MUNTZ, Bart., M.P., Dunsmore (gr. Mr. H. Blakeway), the 1st prize for a feather-weight bouquet. The best floral hair came from Messrs. GUNN & SONS, Olton, Birmingham, and the same firm obtained the 1st prize for a floral cross. Messrs. FELTON & SONS won 1st prizes for a floral wreath and for six button-hole bouquets and six sprays. Mr. J. GARNER had the best basket of cut flowers, and Messrs. FELTON & SONS the 1st prize for a basket of flowers (excluding Orchids). The best stand of cut flowers came from O. ROBINSON, Esq., Alderley Edge.

The best arrangement of cut flowers suitable for a dinner-table arrangement was shown by Mr. J. NIXON, Alderley Edge. It had orange and yellow-coloured flowers including *Gloriosa superba* and yellow Centaureas. There were a large number of exhibits in this class, and they were very gay indeed.

SWEET PEAS.

Sweet Peas were well shown, and the competition was keen. In a class for an arrangement of Sweet Peas on tables, of 4 feet, there were 19 entries. The 1st prize was won by Mrs. JOHN NIXON, Alderley Edge, with a very artistic display of pink Sweet Peas, relieved with golden-coloured Croton leaves and green Selaginellas. The 2nd award went to Mrs. HERBERT, of Acock's Green, who also used pink flowers, but of a paler shade than the last-named. 3rd, Mrs. W. MARBLE, Penkridge.

For 12 distinct varieties of Sweet Peas, arranged on a space of 4 feet by 3 feet, 17 exhibits were placed before the judges, who awarded the 1st prize to Mr. T. JONES, Ruabon, for a magnifi-

cent set of flowers. Mr. GEO. WILKINS being a very close second.

Mr. Robert Sydenham, Birmingham, offered prizes for the best collection of 24 varieties of Sweet Peas, and there were numerous collections staged in this class. The 1st prize was won by Mr. T. JONES, Bryn, Penylan, Ruabon.

Mr. H. Eckford, Wem, Salop, also offered prizes for Sweet Peas.

Messrs. Jones & Sons' 1st prize for six varieties of those flowers was won by Mr. J. HAYCOCK, Wrexham.

Messrs. Bakers', Ltd., Wolverhampton, offered prizes in a class for 12 bunches of Sweet Peas, and the best exhibit in this class was one from Mr. T. JONES, and the best vase of Sutton's Queen in a class in which prizes were offered by Messrs. Sutton & Sons was also shown by Mr. JONES.

CARNATIONS.

Considering the very trying season, Carnations were well shown. The 1st prize in a class for a collection of unadorned Carnations and Picotees to be shown with their own foliage on a space of 6 feet by 4 feet, was won by Messrs. CAMPBELL & SON, High Blantyre, N.B., in whose exhibit we noted two very good varieties named Foxhunter (bright scarlet) and May (Campbell deep crimson). 2nd, Mr. C. H. HERBERT, Acock's Green, Birmingham.

In another class similar to the last-named, but restricted to a space of 4 feet by 4 feet, Mr. J. WALLACE, Esq., Bromborough, had the best flowers, but they were badly set up. 2nd, Miss GLADYS BIBBY, St. Asaph, with a nicely arranged collection, but of rather indifferent quality. 3rd, W. H. BANKS, Esq., Kingston (gr. Mr. G. Bamfield).

Another class was for a collection of Tree Carnations, on a space of 6 feet by 4 feet. 1st, Mr. C. F. WATERS, Balcombe, with flowers of superb quality and beautifully arranged. 2nd, Mr. A. J. DUTTON, York Bucks.

The best exhibit of 12 vases of Carnations, Picotees, selfs, fancies, or yellow-garnets, was shown by C. ALLOCK, Esq., Liverpool (gr. Mr. C. Russell), who had very bright and fresh-looking flowers. 2nd, W. H. PARTON, Esq., Hollywood, Birmingham (gr. Mr. W. Carpenter). There were seven exhibits in this class.

OTHER CUT FLOWERS.

In a class for cut Roses, arranged for effect on a space of 6 feet by 4 feet, Messrs. GUNN & SONS, Olton, Birmingham, were placed 1st with a choice display of flowers, consisting mostly of light-coloured varieties arranged in vases, baskets, and bouquets. 2nd, Mr. GEORGE PRINCE, Longworth. 3rd, Mr. F. M. BRADLEY, Peterborough.

Messrs. ALEX. DICKSON & SONS, Newtownards, won the 1st prize in the classes for 24 Roses, in not fewer than 18 varieties, and 18 cut Roses, in not fewer than 12 varieties. Mr. HUGH DICKSON, of Belfast, being 2nd in each class.

In another class for 18 varieties of Roses, G. H. F. ROBERTSON, Esq., Gresford, beat J. W. HARRIS, Esq., Stone.

In a class reserved for 12 Roses, confined to local growers, Miss HESLER LEAKE, Shifnal, took the lead with a very fine lot of blooms.

Messrs. G. GIBSON & Co., Bedale, had the best exhibit of 18 bunches of hardy flowers, in not fewer than 12 varieties. The examples staged were very fresh and much admired. 2nd, Mr. W. P. RICHARD, Christchurch. 3rd, W. H. BANKS, Esq., Kingston.

The last-named exhibitor secured the leading award in a class for 12 bunches of hardy flowers. 2nd, F. BONSKELL, Esq., Market Bosworth.

For 24 spikes of Gladioli, Messrs. G. MAIR & SON, Prestwich, N.B., led; Mr. JOHN WALKER, Thame, being 2nd.

In a class for 12 spikes of Gladioli, H. F. ROBERTSON, Esq., Gresford, was placed 1st with a wonderfully large, substantial set of flowers. 2nd, the Marquis of NORTHAMPTON, Castle Ashby, Northampton (gr. Mr. A. R. Searle).

In another class for the same number of spikes of Gladioli, but confined to exhibitors residing in the county of Salop, Mr. J. WITHINGTON, Cherrington, was placed 1st.

In a class for a collection of Cactus or decorative Dahlias or both, there were exhibits from most of the principal growers, and excellent displays were made. The prizes were awarded as follows: 1st, Messrs. M. CAMPBELL & SON, High Blantyre, N.B.; 2nd, Messrs.

KEYNES, WILLIAMS & Co., Salisbury; and 3rd, Mr. WM. TRESSEDER, Cardiff.

Most of the same exhibitors entered into the competition for the best collection of Dahlias (any varieties), and Messrs. KEYNES, WILLIAMS & Co. won the 1st prize. Mr. M. V. SEALE, Sevenoaks, was 2nd, and Mr. J. WALKER, High Street, Thame, 3rd.

In a class for 24 Cactus Dahlias Messrs. BOTTOMLEY & BERTON, Elland, Yorks, won the 1st prize, and Mr. W. TRESSEDER, Cardiff, the 2nd prize.

Mr. W. E. WILSON, Cannock, was awarded the 1st prize in a class provided for 18 Cactus Dahlias and in another class for 12 Cactus varieties.

Mr. M. V. SEALE, Sevenoaks, had the best 12 varieties of Cactus Dahlias, six blooms of each, arranged in vases with foliage, berries, &c. 2nd, W. BANKS, Esq., Kingston.

Messrs. H. J. CLARKE & SON, Rodley, Leeds, had some wonderfully fine Asters, and Messrs. G. GIBSON & Co., Bedale, showed the best half-dozen bunches of *Galadiarias*.

The best exhibit of 12 bunches of herbaceous Phlox was staged by N. G. HARRIS, Esq., Wolverhampton (gr. Mr. Jas. Pugh), and the 2nd prize by Mr. M. FRICHAUD, Christchurch.

The best 12 bunches of hardy annuals were shown by W. E. BARRETT, Esq., Bishop's Castle (gr. Mr. H. J. Edwards). He had *Zinnia*, *Double Scarlet*, *Giant White Sweet Sultan*, *Ceropepis Drummondii*, *Lavatera rosea splendens*, *Lupinus hybridus atrocarocinus*, *Steck Perfection*, *Salpiglossis*, *Nigella Miss Jekyll*, *Phlox Drummondii grandiflora*, *Nemesia*, *Godetia Double Rose*, and *African Marigold*.

There was much competition in a class for a collection of hardy perennials (Roses excluded), staged on a table with a frontage of 10 feet and a depth of 6 inches. No duplicates or mixed bunches were allowed, and for a breach in this respect Messrs. G. GIBSON & Co., Leeming Bar, Bedale, were disqualified, who would probably have been awarded the 2nd prize. The 1st prize was won by Messrs. GUNN & SONS, Olton, Birmingham, and A. BRYDON, Esq., Innerleithen, N.B., obtained the 2nd prize, Mr. M. P. RICHARD, Christchurch, being awarded the 3rd prize. The exhibits made an excellent and very happy display of bloom, but the tent was inconveniently crowded with visitors during most of the time the exhibition was open.

The 1st prize for 12 bunches of stove or greenhouse flowers was awarded to T. SUTTON TIMMS, Esq., Allerton, near Liverpool (gr. Mr. B. Cromwell); Mrs. M. JOWETT, Huyton, Liverpool (gr. Mr. E. Bridges), obtained the 2nd prize. The exhibits in this class made a very gorgeous display.

VEGETABLES.

When it is stated that in competition for the trade, and the Society's classes for nine dishes of vegetables each, no fewer than 62 collections were staged, showing a total of 568 dishes, and that in other classes some 700 to 800 other dishes were shown, it will readily be understood what a wonderful lot of vegetables was seen. In addition to all these, Messrs. CLIBRANS, of Altrincham, put up an exhaustive collection of some 150 dishes, including many very fine specimens of Onions, Potatoes, Carrots, Tomatoes, Peas, Beets, and other kinds. Messrs. SUTTON & SONS, Reading, arranged in a superb group very many and extremely handsome dishes of Tomatoes, both red and yellow, also Potatoes, Cucumbers, Beans and other kinds.

(Classes in which prizes were offered by trade exhibitors.) Necessarily, these classes, with their liberal cash prizes, attracted the leading growers, and this year the excellence of the chief exhibits was such as never before has been equalled. Taking these classes in schedule order, first come Messrs. J. CARTER & Co.'s class for nine dishes, with six prizes of the value of £17 10s. Here Mr. I. Dymocke (gr. to G. D. FABER, Esq., Wallingford) was a good first. He had very fine *Quite Content* Peas, Carter's Scarlet Runners, excellent *Alisa Craig Onions*, good *Celery*, *Leeks*, *Tomatoes*, *Carrots*, *Cauliflowers*, and *Windsor Castle Potatoes*. Mr. B. ASHTON (gr. to the Earl of LATHOM, Ormskirk) was second, with capital products. Mr. Searle (gr. to the Marquis of NORTHAMPTON), Castle Ashby, was 3rd, and Mr. Hallett (gr. to Sir J. HESKETH, Worcester), was 4th.

Somewhat keener competition was seen in the class also for nine dishes, in which prizes were offered by Messrs. Sutton & Sons, Reading, to the value of £17. Here Mr. E. Beckett (gr. to

the Hon. VICARY GIBBS, Aldenham House, Herts.) was a capital first, having exceptionally fine Giant Cauliflowers, Prizetaker Leeks, very stout, fine white Celery, superb Ailsa Craig Onions, Abundance Potatoes, Perfection Tomatoes, Best of All Runner Beans, New Red Intermediate Carrots, and splendid Duke of Albany Peas. Mr. Dymocke was second, having also very fine vegetables and Mr. J. Gibson (gr. to the Duke of Portland, Welbeck Abbey), 3rd. Mr. Gibson's Peas, Celery, and Tomatoes being specially fine. Mr. SEARLE was fourth.

Messrs. R. Smith & Sons, Worcester, offered four prizes, total value £11, for collections of nine dishes. Mr. H. Gaiger (gr. to H. T. Tatham, Esq., Elstra) obtained the 1st prize, showing capital Onions, Tomatoes, Cauliflowers, Peas, and Potatoes. Mr. SEARLE was 2nd, and Mr. HALLET 3rd.

In Messrs. Webb & Sons' class, a collection of nine dishes were required, and the prizes were six in number, amounting to £10. The Mr. BENNETT was 1st, repeating the kinds shown in a previous class. Leeks, Celery, Onions, Peas, Tomatoes, Carrots, Beans, Potatoes, and Cauliflowers were all of high-class quality. Mr. DYMOCCKE was an excellent 2nd, Mr. SEARLE coming 3rd, and Mr. B. ASHTON 4th. The firm also offered very liberal prizes for a dish of one of their varieties of Tomatoes. Beautiful samples were staged, all of rich colour and perfect form.

There was also competition in Mr. E. Murrell's (of Shrewsbury) class, again for nine dishes. Here Mr. J. Edwards (gr. to W. E. BARNARD, Esq., Bishops Castle) was 1st, other prizes being taken by Mr. J. H. PUGH, Newtown, and Mr. Cook (gr. to W. J. LOVELL, Esq., Wellington).

Only four collections of dishes were entered for Mr. Robert Sydenham's very liberal five prizes, representing a cash value of £28, with valuable articles of plate and glass. The 1st prize fell to Mr. S. J. Baker (gr. to Mr DYCE DUCKWORTH-KING, Exeter), whose collection included first-rate Onions, Tomatoes, Runner Beans, and Potatoes. Mr. W. H. JONES, of Newtown, was 2nd, and Mr. E. DEAKIN, Birmingham, 3rd.

The chief tug-of-war, however, in the vegetable section was found in the class for nine dishes, the prizes being £10, £7, £4, £2, offered by the Society. Here both Messrs. BAKER and GIBSON had put out their fullest strength, resulting in two very splendid collections that ran each other closely. Mr. BECKETT just winning the 1st prize. We may be disposed to think a finer collection never has been seen at Shrewsbury than was this one. It was subsequently awarded the challenge prize of 10 guineas, after being pointed by the whole of the six vegetable judges. Mr. J. GIBSON, who came 2nd, had most superb Centenary Peas, Ideal Potatoes, very perfect Tomatoes, splendid Cauliflowers, Celery, Runner Beans, and other kinds. Mr. J. HULLSON, Leicester, was 3rd, and Mr. ASHTON 4th. The following represented the joint awards for the challenge prize collection:—

	Points	Avail.	Maximum
Cauliflowers	7	7	7
Leeks	7	7	7
Celery	7	7	7
Onions	7	7	7
Carrots	7	7	7
Potatoes	6	7	7
Tomatoes	6	7	7
Runner Beans	6	7	7
Peas	6	7	7
Total	61	63	

Mr. BECKETT's collection, therefore, had five maximums, and with 63 points won the challenge prize.

In two separate classes, Mr. BAKER had the finest six Onions, in splendid bulbs of Ailsa Craig. For *Messrs. Dickson & Robinson's* prizes, Mr. Wilkinson (gr. to G. A. GIBBS, Esq., M.P., Bourton) was well 1st with clusters carrying 12 handsome ripe fruits on each. For three dishes of Potatoes, Mr. Cook won the 1st prize with handsome samples of King Edward VII., Duchess of Cornwall, and Factor. Mr. B. ASHTON coming 2nd with Empire (white round), Ruby Queen (purple round), and Chieftain (large flat, white, rather coarse). Mr. E. DEAKIN had the two best dishes of Peas in excellent Duke of Albany and

Gladstone. Mr. J. HULLSON, Leicester, had truly wonderful Runner Beans, coming 1st amongst many. Mr. DYMOCCKE had the finest Parsnips, Mr. GIBSON the best four Carrots, and Mr. BECKETT the handsomest four Turnips.

HONORARY EXHIBITS.

Messrs. ED. WEBB & SONS, Wordsley, Stourbridge, had a very gay exhibit in the fruit market, including handsome epergnes of Sweet Peas, Carnations, Gladstone's, Tomatoes, Peas, Beans, Potatoes, Marrows, Turnips and other vegetables in choice varieties. Mr. ED. MURRELL, Portland Nurseries, Shrewsbury, had an exhibit of Roses and Gladioli, also a few plants of Clematis in pots.

Messrs. WM. CUTBUSH & SON, Highgate, London, contributed a grand display of Carnation blooms, many of them being displayed in tall stands. Sprays of Rambler varieties of Roses were included in this exhibit.

A collection of orchard house trees in pots shown by the KING'S ACRE NURSERIES COMPANY, LTD., were remarkable for the finely-cropped Apple and Peach trees. All the trees exhibited excellent health, but the Apples were most freely cropped. From the same firm there was displayed a collection of hardy flowers.

Messrs. GEO. BUNYARD & CO., Royal Nurseries, Maidstone, made an exhibit of choice fruits, including Apples, Peas, and Plums. There were excellent fruits of the finely-cropped new Apple, Lord Castleburgh, and many other varieties. In all there were 65 dishes staged. Messrs. BAKERS, Coltsall and Wolverhampton, had one of the most extensive exhibits of cut flowers, showing a fine display of Dahlias, and another one composed of most hardy flowers at present in bloom.

Mr. HUGH DICKSON, Belfast, made a good exhibit of Roses, showing some of the flowers in Tampion stands and others in the ordinary show boxes.

Messrs. J. S. SAMPSON & SONS, Exeter, had a brilliant group of flowers, which faced visitors as they entered the fruit tent. It was mainly composed of Sweet Peas, Dahlias, Carnations, and Begonias.

Mr. AMOS PERRY, Enfield Nurseries, Middlesex, arranged one of his characteristic exhibits in a hall-circular space in the great plant tent. A large amount of stone had been brought from London, and considerable water tanks were judiciously ornamented with choice Water Lilies, bright hardy flowers, and other tastefully disposed on the side of the water contributed to make a very extensive and attractive exhibit.

Messrs. HEWITT & CO., St. Hill and Birmingham, had a magnificent exhibit of flowers in great numbers.

Roses formed the exhibit from Messrs. GUNN & SONS, Olton, near Birmingham. Messrs. R. WALLACE & CO., Kilmfield Gardens, Colchester, made an excellent display of hardy flowers, and in this exhibit the kinds were massed separately, there being groups of Gladioli, Lilium, and Montpeliers. The Montpeliers were delightfully attractive, and they carried the newer varieties such as Prometheus and others.

Messrs. PRITCHARD & SONS, Shrewsbury, showed a few Ferns, but the arrangement of diminutive examples on the cork table was not attractive.

Messrs. W. M. STANTON & SONS, Nether Green, Shrewsbury, had an exhibit of hardy flowers, and, in addition, staged Vinolas and sprays of border Chrysanthemums over a groundwork of black velvet. A good display of these Vinolas was included.

Messrs. WELLS & BRAND, Salton Walden, Essex, showed their excellent double Hollyhocks in a smart fashion in their exhibit in the R.H.S. Hall, London.

Messrs. G. STARR & SON, Great Ryburgh, exhibited a small collection of new varieties of Sweet Peas. Mr. THOS. W. DICKSON, Watton, Cambridgeshire, showed Sweet Peas of very good cultivation, and Mr. ROBERT BOSTON, Watton, had a similar good group of these flowers. A small group of Cactaceous plants was shown by Miss S. S. DUMPHRIES, Handsworth, Shiffield.

Free Admission. But Nurseries, Gwent, were shown Gladioli, Montpeliers, and Galtonia candicans as cut flowers.

Messrs. W. J. BROWN, Stamford and Peterborough, made an exhibit of Roses in which most types were given a place.

Messrs. DORRIS & CO., Rothsay, sent a very bright group of hardy flowers, comprising varieties of a variety of Dahlias, together with a good selection of Viola and Panicle and a few other miscellaneous flowers.

Messrs. HUBBES, LTD., Dereham, occupied a crescent-shaped display in the fruit tent with a pleasing arrangement of cut Roses and weeping varieties on tall stands.

Messrs. SUTTON & SONS, Reading, had a magnificent collection of Onions, Tomatoes, Cucumbers, Beans, Potatoes, &c. The back of the group consisted of articles of furniture and other sorts.

Mr. A. MYERS, Sutton Lane, Shrewsbury, had a collection of Zonal Pelargoniums and miscellaneous foliage plants. Messrs. DICKSONS, Chester, showed a very fine collection of cut flowers in pots and boxes. Messrs. ISAAC HURST & SON, Westbury-on-Trym, staged two varieties of Phloxes and a small collection of Alpine plants and other hardy flowers. They also showed a flower of the uncommon *Aristolochia gigantea*, from America. KELWAY & SON, Langport, were shown upwards of 200 spikes of sharply Gladioli flowers. The biggest and best display of the fragrant hardy Phlox came from Messrs. GUNN & SONS, Olton, Birmingham, who showed some of the best varieties in show, as well as a number of promising unnamed seedlings.

Mr. JOHN FORBES, Hawick, N.E., contributed a large assortment of bold, variously-colored Pentstemons and Phloxes, together with a good collection of Carnations (based on the old-fashioned Snow-bird).

Messrs. T. RIVERS & SEN, Sawbridgeworth, had an interesting group of heavily-laden fruit trees in pots and potted plants, Peaches, Nectarines, Apples, Pears, Plums, Figs, Lemons, &c. were included in this meticulous display.

Messrs. ALEX. DICKSON & SONS, Newtownards, staged a very fresh lot of Roses in Bamboo stands and boxes.

Mr. A. W. THORPE, Lichfield, had a prettily-arranged group of early-flowering Chrysanthemums.

From Mr. SANKEY, Baschurch, came a group of showy double-flowered Sweet Peas, which were ready. The flowers were large, richly coloured, and borne in great profusion.

Mr. VINCENT SLADE, Taunton, set up a bright display of cut flowers of double and single-flowered Zonal Pelargoniums.

Mr. JOHN SMELLIE, Bury, N.E., showed a selection of decorative and single-flowered Chrysanthemums.

HUGH AIDERSLEY, Esq., Chester, had an interesting group of seedling Phloxes.

Mr. W. ANGUS, Penicuik, Scotland, had a small but grand lot of *Disa grandiflora* and flowers of a new variety of Chrysanthemum maximum named "Snow-ling," remarkable for its large, thick, pure white petals.

Mr. C. H. HERBERT, Acree's Green, Birmingham, had flowers of a new perpetual-flowering Pink named "Proserpine." The colour is pale pink.

From ROBERT SYDENHAM, LTD., Birmingham, came Sweet Peas arranged in rustic stands. Also bearing flowers of the Valley, Spiraeas and Liliums related in profusion in highland and growing well in fibre without drainage.

Messrs. HUGH LOW & CO., Enfield, had a large display of Carnations and Ferns.

Messrs. DICKSON & ROBINSON, Manchester, staged a group of exhibit with Dahlias as a background and Tomato "Money-maker" in the foreground. The latter was shown in trusses of from 18 to 20 fruits of good size and shape. Sweet Peas in variety were also shown.

Messrs. CLIBRAN, Altrincham, had an excellent collection of over two varieties of vegetables, including Clibran's White and Clibran's Green, which were of good quality and large size. Parsley Clibran's Exhibition, well curled, Broad Bean Clibran's Exhibition, large pods containing 12 to 14 beans, Onion Clibran's Exhibition, a hybrid between Ailsa Craig and Excelsior, and many varieties of excellent Tomatoes.

Mr. GEORGE PRINCE, Longworth, Berks, had a good collection of Roses in many varieties and well arranged.

Mr. HENRY CROFT, Weymouth, staged a choice and well-displayed collection of his latest novelties of Sweet Peas, including Annie B. Gilroy, crimson-red, Valley Bell, new bicolor variety with salmon-pink standard and creamy wings; Improved Lord Kosby with four flowers on each spike, deep rose-carmine with well-expanded standards, &c.

Mr. PETER BLAIR, Trentham Gardens, Staffordshire, showed a fine white border Carnation named Mrs. Tom Cuthwaite, who has already been awarded an award of merit by the Floral Committee of the R.H.S. It has a splendid habit, and the calices are usually non-splashing.

Messrs. TOM DORES & CO., Queen Square, Wolverhampton, exhibited rustic arches and similar structures on the grass out-of-doors.

Messrs. JARMAN & CO., Chard, staged many vases with their plants. The Bride, Bridgemoor, Bridesmaid and Honeycomb.

Messrs. ROBEY SYDENHAM LTD., Birmingham, had a fine collection of Sweet Peas well arranged in their "Rural Table Decorations," and showing how well these delicate flowers could be nicely displayed in inexpensive vases. We noted many good blooms of all the newer varieties.

Messrs. HUGH LOW & CO., Bush Hill Park, London, exhibited Carnations, Roses in Pots, dwarf Tampions, Ferns, &c.

HONORARY AWARDS.

LARGE GOLD MEDALS.

Dibbie and Co., Robesay, for Cactus Dahlia 'Sentinel'; Mr. Charles Acock, Blundellsands, for Carnation Mrs. Charles Russell; and Messrs. A. Jackson and Sons, Ltd., Newtownards, for hybrid Tea Rose 'Lena'.

BRIGHTON HORTICULTURAL

AUGUST 18 & 19.—The seventeenth annual exhibition of this Society was held as usual at the Royal Pavilion, and was again a success. Beneath the dome of the building was arranged a bold display of flowers, the centre of the exhibits being composed of tables of flowering and foliage plants, including many Sweet Peas, whilst hardy perennials occupied the staging around. The concert platform was artistically arranged with Dracaenas, Fuchsias, Codaeums (Crotons), and other foliage plants, with an edging of Begonias. There were no fewer than 17 decorated tables in a competitive class.

In the open class for a circular group of flowering and foliage plants arranged for effect, Messrs. GEO. MILES & SON won the 1st prize with a neatly-arranged group, consisting of Liliums, Carnations, Begonias, Dracaenas, Ferns, &c. W. PINGO HOBSON Esq., Cravenhurst, Seaford, was awarded the 2nd prize.

For a circular group of Ferns measuring 12 feet in diameter, Mr. Edward Jones (gr. to HARRY YOUNG, Esq., Withdean Grange, Brighton) won the 1st prize easily with a beautifully-arranged group, in which Nephrolepis exaltata toledoides figured conspicuously. This exhibit was awarded the Corporation Challenge Bowl, offered for the best exhibit in the show. 2nd, Messrs. GEO. MILES & SON.

The 1st prize for a table of flowering and foliage plants was won by Mr. Geo. Chandler (gr. to S. C. WHITTING, Esq., Brighton); 2nd, Mr. H. Goldsmith (gr. to DANIEL HACK, Esq., Withdean).

The only collection of cut Carnations was shown by Mr. C. F. WATERS, Balcombe, and he was given the 1st prize, which consisted of a Silver Challenge Cup and this Society's Silver Medal.

A class for a collection of Sweet Peas arranged with any kind of foliage or plants on a table, brought 11 entries. The 1st prize, which included a Challenge Cup and the Society's Silver Medal, was won by Mr. C. F. WATERS with a splendidly-arranged exhibit of good quality blooms; 2nd, Mr. W. H. SICKLEMORE (gr. to Major WEBBER, Chisleholme).

The 1st prize for a collection of hardy perennial and bulbous flowers was secured by Mr. Hugh MacFadyen (gr. to J. BREITMEYER Esq., Cuckfield Park); 2nd, Mr. J. DAVIS (gr. to Major E. H. THURLOW, Uckfield).

Mrs. H. WALTER, Park Road Nursery, Worthing, arranged the best decorated table. Messrs. J. CHEAL & SOXS won the 1st prize in the class for 20 show or fancy Dahlias, also for Pompon varieties. In the class for Cactus Dahlias the premier award went to Messrs. JAMES STREIGHWELL & SON, St. Leonard-on-Sea; 2nd, Messrs. CHEAL & SON.

There were several classes open only to private gardeners and amateurs. In the class for a circular group of miscellaneous flowering and foliage plants, Mr. EDWARD JONES was again placed 1st, thus securing the handsome Silver Cup and Society's Silver Medal; 2nd, Mr. GEO. CHANLEY.

The best Muscat of Alexandria Grapes were shown by Mr. W. M. MANCEY, Merstham, and the best bunches of Black Hamburgh by Mr. CHAS. EARL.

Mr. T. BRACKLEY, Oaklands, Hassocks, won in the class for a collection of nine kinds of vegetables.

Non-competitive exhibits were staged by Messrs. CHAS. & SOXS, Crawley; Messrs. BALCHIN & SONS, Brighton; Mr. FRANK WOODLARD, Brighton; the BARNHAM NURSERY CO., and others.

again. *L. lanceifolium* is abundant. Lily of the Valley remains good plants for best quality spikes. Stephanotis and Tuberoses are plentiful, but Gardenias and Eucharis are scarce. Carnations are plentiful and cheap. During the past four years I have never known an occasion when blooms of Luchsstrans, Mrs. Lawson, and other popular varieties were not procurable. Roses vary considerably; a few choice flowers are seen, but the best blooms are of second quality or small. Asters are abundant and their prices are low. Those of the Ostreich Plumbe and the Comet varieties are most appreciated, but there are others which are more productive and perhaps as profitable to cultivate. The double-flowered *Gypsophila* is now at its best, also several species and varieties of Statice. The supply of cut foliage of all description is more than equal to the demand. Hardy foliage includes Berberis (Malton), bronzy tinted Oak shoots, also Viburnum Opulus with its bright red berries.

PLANT SALES.

Well-flowered Chrysanthemums are a feature; they are chiefly of the "Masseé" type, but some good plants of Lady Fitzgibbon are also seen. Asters in pots are very good; these have been grown in the open ground and afterwards potted. There are no *Ericas* at present, but I learn there will soon be plants of *E. gracilis* in the market, and *E. lycemalis* will be seen in the trade this season. *Verbenas* are plentiful. *Lilium lanceifolium rubrum* of good quality has been selling very cheaply. Heliotropis, Fuchsias, Campanulas, Impatiens, and Marigolds are all plentiful. Low summer-flowering Chrysanthemums are all procurable. The trade in foliage plants varies but little; business for all pot plants is so good that many studios will remain empty for several weeks to come. *A. H., Cecile Garden, Wednesday, August 19, 1908.*

Obituary.

ALDERMAN BALDERSON.—We regret to have to record the death on August 12, at his home, 3 Corner Hall, Boxmoor, Herts., of Mr. Henry Balderston, at the age of 77 years. For several years he was one of the vice-chairmen of the Fruit and Vegetable Committee of the Royal Horticultural Society, especially during the 5th Derby Hall days. He was a devoted amateur gardener, taking the deepest interest in everything appertaining to horticulture and brought to the consideration of all subjects that came before the committee much keen criticism. He was of a genial, joyous disposition. A merchant in the City of London, he was very popular at his home at Hemel Hempstead, and enjoyed the confidence of the inhabitants of that town, of which he was appointed mayor in 1900. Deceased was also vice-chairman of the Board of Guardians, chairman of several of the important committees of the Town Council, and trustee of Boxmoor since 1871. For 51 years he was churchwarden of St. John's Church, Boxmoor, also a director of the Waterworks Company and chairman of the Gas Company. He was in addition a prominent Freemason and an able supporter of friendly societies in general. Deceased was born at Cadebridge in 1830, when the population of Hemel Hempstead numbered about 3,000 persons. Nearly 40 years ago he was baptised of the town, and in that year the local horticultural society, of which he has always been a strong supporter, was started. The deceased gentleman leaves six daughters and one son; his youngest son was killed in the South African war.

GEORGE COOKE.—We regret to learn from the United States that Mr. George Cooke, the well-known landscape gardener of New York and a partner of Mr. Samuel Parsons, was the victim of the 6th inst. of the epidemic that in California. He was driving in the mountains near Alpine, San Diego, when the horses ran away and he was thrown out, receiving injuries from which he died. The late Mr. Cooke was a native of Leicester. He will be remembered by many of our readers as gardener for several years at Quorn House, near Loughborough. When a young man, and before going to Quorn, Mr. Cooke went to Canada, where he held out for several years at Quorn. Mr. Cooke proved his ability as a good gardener, especially as a cultivator of Orchids and Nephelias; he was the first to flower the white form of *Cattleya Mendelii*, known as the Quorn House variety. On the death of his employer about ten years ago, Mr. Cooke went to the United States to lay out the estate of Mr. H. McK. Twombly, at Madison, New Jersey, and about eight years ago became associated with Mr. Parsons. At the time of his death Mr. Cooke was residing in San Diego, and filling the responsible position of chief engineer to the San Diego City and County Boulevard Commission. Much sympathy will be accorded his widow and daughter by his many friends in this country.

ANSWERS TO CORRESPONDENTS.

APPLE WEEVIL: *Z. A.* Spread cloths beneath the trees and shake the branches, when the weevils will fall to the ground. At the end of September they retire for hibernation, hiding in crevices in the bark of Apple and other trees, or concealing themselves beneath lichens and mossy growths upon the branches, as well as under stones and rubbish beneath and around the trees. The weevils do not appear until the weather is mild and the flower-buds have begun to swell. Varieties of Apple trees which blossom very early and very late are more likely to escape the attacks of the weevil than those of the main crop whose blossom comes late in May in ordinary seasons. It is recommended to spray the branches in February with caustic alkali wash, for this will destroy the lichens and mosses which serve as harbours for the weevil and other insects. All leaves and other rubbish underneath fruit trees should be cleared away. It is also advantageous to spray the trees with kerosene emulsion, made by dissolving 2 lbs. of soft soap in boiling water, adding 2 gallons of kerosene or paraffin oil, and churning the whole until well mixed. This quantity is sufficient to add to 40 gallons of water.

BEECH TREES, NC.: Beech. The trouble is probably caused by drought. Water the roots copiously, using alternately liquid manure. Send a sample of the grass for examination.

BOOK FOR PERN-PRESSING: *F. J. B.* We do not advise the use of a book for plant-pressing. Dry them between old newspapers or periodicals. Place each frond on a separate sheet of white paper, and put a weight on the top to keep them flat. Shift the leaves frequently so that the drying may be hastened, and when they are perfectly dry, attach them to the leaves of a scrap-book, naming each one correctly. A suitable book for the purpose can be purchased from most stationers.

ELM TREES: *W. G. Z.* No harm should result from the application of the soil to the roots, provided it is kept clear of the stem for 2 or 3 feet.

GLOXINIA LEAVES INJURED: *Correspondent.* The damage has been caused by thrips. Sprinkle the plants with water containing a little tobacco extract and soft soap in the proportion of 1 oz. of soap to two gallons of water.

HERGE: *H. F. Z.* We should prefer to substitute *Cupressus Lawsoniana* or *C. nutkanensis* for *C. macrocarpa*. The common Beech makes a splendid hedge and a fine wind break in winter. The Quick or Thorn is well known, also Hornbeam and *Prunus myrobalana* or Cherry Plum, all of which are suitable. When well established, *Berberis Darwinii* makes good growth and is a success as a hedge plant. Do not employ Privet. The best time to plant is about the end of September.

HOUSE INFESTED WITH MEALY BUG AND OTHER PESTS: *J. P.* Fumigate the house with cyanide of potassium gas. See directions in the issue for April 23, 1904, p. 271.

LILIUM GIGANTEUM: *C. H. B.* Remove the offsets and plant them where they are required to flower. The old bulb dies after flowering.

LOAM: *M. Johnston.* The sample of turf is excellent, both in regard to the amount of fibre it contains and the general character of the loam. Your communication should have been addressed to the Editor, not the publisher.

NAMES OF FRUITS: *Asford.* 1, Mr. Gladstone; 2, Early Harvest (Early Juncating)—*G. H. 1* and 4, send later, the fruits are too immature to name; 2, Cox's Pomona; 3, Domino; 5, Beauty of Bath; 6, Lord Derby.—*A. A. B.* The Apple resembles Irish Peach. Please send another specimen.

NAMES OF PLANTS: *A. F.* *Gentiana asclepiadea.*—*H. B.* *Anemone japonica* (seedling variety),—*H. J. P.* 1, *Heliospis levis*; 2, *Heliospis autumnale capreum*; 3, *Centaurea rubra* (probably); 4, *Achillea filipendula.*—*M. H. W.* 1, The curling is due to local conditions, there is nothing on the leaves; 2, *Heliospis scabra*, 3 and 4, both forms of *Helianthus multiflorus* var. *flor. pleno.*; 5, *Helianthus autumnale capreum*; 6, *Campaulna rapunculoides*; 7, *C. lactiflora*; 8, *Aster*, cannot be

named more precisely without flowers; 9, *Aster puniceus.*—*F. G. B.* *Ecremocris scaber.*—*C. H. W.* *Retinospora squarrosa*, a juvenile form of *Cupressus pisifera*—*J. B.* We do not undertake to name varieties of Carnations.—*W. F. Z.* 1, a species of *Polygonum*, too withheld for identification; 2, *Saponaria officinalis*, double-flowered variety—*Togo.* 1, *Trachelium corollatum*; 2, *Hoya bella*; 3, *Crassula* (*Kalosanthe*); *scincina*; 4, *Cyperus latifolius*; 5, *Juncus polinaria*.

NYPHÆA: *G. H. R.* *Nymphæa odorata Carolina* will be suitable for your purpose. It should be planted in April or May, certainly not in October. You must use not less than 1 foot deep of soil, but do not add any manure. On no account introduce any water weed: the *Nymphæa* will be quite sufficient, and both fish and *Nymphæa* will thrive without a constant flow of water. In regard to the pond-scum, an occasional dressing with the Bordeaux mixture, using for your pond about one quart of a pound, which may be dusted on the surface. The best work on aquatics is *The Book of Water Gardening*, by Peter Bisset. New York, A. T. De La Mare Printing and Publishing Co., Ltd., 1907.

PAWAW FRUITING: *J. S.* Kindly send a specimen of the plant with, if possible, an inflorescence.

PEACH STONE SPLITTING: *P. K.* In sending soft fruits, such as Peaches, through the post, a wooden or tin box should be used. The fruit you sent packed in cardboard and wood-wool was crushed. See reply to *E. G.*

PEACHES, E. G. The variety Dymond is not one in which the fruit stones are very liable to split, and we cannot account for this taking place in your case, unless the tree has been too liberally fed, either by rich compost or liquid manures. In the latter case spitting would be the more likely to happen if the border was very dry before a liberal watering was given. The mischief might also be caused from extreme atmospheric conditions, such as extreme fluctuations in regard to the degree of atmospheric moisture during the time the fruit is swelling. The fruits of the Peach do not often drop after their stones have formed, until they are perfectly ripe. Before the stoning process is completed, however, fruit-dropping is likely to happen if the trees are subjected to excessively high temperatures. Provided the border is properly formed, and the tree is perfectly healthy, careful attention to cultural details should prevent the recurrence of the evil.

PLANTS FOR A MOIST BANK: *A. T. B.* In the following list will be found a number of plants suitable for furnishing your moist bank: *Aralia racemosa*, *Epilobium angustifolium*, *E. hirsutum*, German Irises, *Rudbeckias*, *Polygonums* (Knot Weeds), *Doronicums*, *Acogonium* (Monkshood), *Helianthus*, *Saxifraga aruncus*, *S. palmata*, *Solidago* (Golden Rod), *Lythrum salicaria* (Loose Strife), *Helianthus*, *Galega officinalis*, *Michaelmas Daisies*, *Heimerocallis* (Day Lilies), *Moarada didyma* (Bergamot), *Chrysanthemum maximum*, *Trollius* of sorts, *Funkias*, and *Lupines*.

POTATOS DISEASED: *A. C.* The tubers you send are badly affected with the black scab or warty disease—(*E. Olomyces leproides*) (see p. 146 and fig. 58).

ROOTS WITH MILLIPEDS: *W. U.* *Stoke-on-Trent.* The creatures attacking the roots of your plants are specimens of the "spotted snake millipede" *Blungolus gubulatus*, a well-known pest. The smaller ones are immatures. Dress the ground thoroughly with "Vaporite" or "Apterie," which are said to kill these creatures, or with gas-lime. None of the ordinary insecticides affect them.

SOIL EXHAUSTED: *E. G. H.* You appear to have over-dosed the land with chemical manures. Apply a dressing of slaked lime and well fork it in.

TOMATOS DISEASED: *W. A.* See reply to *R. R.* in the last issue, p. 120.

COMMUNICATIONS RECEIVED.—*H. Bro.*—*F. F. E. P.*—*Col. G. C.*—*B. F. K.*—*M. T. Hillfield*—*Wm. J. F.*—*G. F. S.*—*J. E. K.* & *B. K.*—*M. F. G.*—*W. G. L.*—*Marple*—*E. W. C.*—*T. H. B.*—*E. S.* & *Son*—*J. B. S.*—*F. P. T.*—*W. C.*—*Constant Reader*—*J. R.*—*J. E. T.*—*E. F. J. C.* & *Co.*—*R. T. C.* & *Son*—*J. D.*—*I. O.*—*A. B. W.*

WREST PARK, BEDFORDSHIRE.

(See figs. 61, 62 and 63, also Supplementary illustration.)

WREST PARK is the most stately country home in the county of Bedford; Woburn Abbey may be better known, and Luton Hoo is larger, but for variety of scenery and beauty of design the palm must be given to Wrest. Though situated only about forty miles north of London, it lies sufficiently far away from rail and high road to be undisturbed, and it was doubtless from the fact that the Metropolis could be easily reached, combined with the comparative seclusion of the well-kept grounds, that the American Ambassador, the Hon. Whitelaw Reid, leased it as his country seat in August, 1905, very shortly after the Right Hon. Lord Lucas came into possession through the death of his maternal uncle, the seventh Earl Cowper, K.G.

The mansion was built by Earl de Grey: it is in the French style of architecture, but an earlier building stood on a site in the pleasure grounds more to the south. The older structure seems in the Earl's time to have been famous for its cracked walls and long passages, incapable of any essential repair or im-

provement. It was his intention at first to erect a new mansion piecemeal on the same spot near where a splendid Carrara marble fountain now stands, but that idea was given up in order to build on higher ground to avoid the mists rising from the lakes. His lordship's idea was to preserve the relative positions of the ornamental parts of the gardens and the original character of the place. With this in his mind, every tree was studied and several plans were made and altered. In 1834 the present house was commenced, and in 1839 it was used as a residence. Earl de Grey, F.S.A., was his own architect, and he personally designed and supervised the building with indomitable perseverance.

The house stands at the end of a double avenue of Elms and Spanish Chestnuts, which commences at the handsome wrought-iron gates separating the deer park from the model

Drive." These lofty Elms have withstood many an autumnal blast and have been silent witnesses of many changes in the Kent family.

This leads us to digress for a moment to mention that the Barons Grey or De Grey descended from Anchtal de Grey, who lived in the time of William the Conqueror. A descendant of his, known as Reginald Grey of West, had an heir who was also Lord Grey of Wilton. His grand-son, Reginald Lord de Grey of Ruthyn, was Lord High Admiral of England, and it was he who probably erected the nave and tower of Flitton Church hard by, the last resting place of the De Greys. The Reginald in Edward IV.'s reign was created Earl of Kent in 1465. Henry, fifth earl, was one of the Judges at the trial of Mary Queen of Scots in 1587. Amabel, wife of Henry, the ninth earl, who

FIG. 61.—THE ROCKERY, WREST PARK GARDENS.

ville of Silsoe, situated on the main London road between Luton and Bedford. The north entrance is reached by a drive, which formerly was void of beauty, but Mr. Whitelaw Reid has greatly enhanced the spot by planting on each side of the entrance a variety of choice flowering shrubs, both deciduous and evergreen, and now during the spring and summer there may be seen bright colours, and in autumn Ampelopsis Veitchii on the walls behind give a mellow tone. Between these protected patches is an enclosed green, which is kept closely cut, so that the outlook on the park side is a decided improvement. The park itself is worth a visit. A noble avenue of Elms not only skirts the northern and western sides, but is continued far beyond, being formerly used as a drive and it still retains the title of "Duke of Kent's

fought against Charles I. in the Civil War, went by the name of the "Good Countess," for, during her long widowhood of forty-seven years she did much for the house and the estate. There is a long inscription on her tomb in Flitton mausoleum, placed there by her grand-son, stating that "she had time to restore the fortune of this illustrious family, which she found under an eclipse, to near the height of its ancient splendour." She redeemed and considerably improved the family estate at Wrest, "continually adding to the profit or ornament of the place." Her son Anthony married the sole heiress of John, Lord Lucas, Baron of Shenfield in Essex, and obtained from Charles II. in 1663 letters patent creating his daughter (he had no son) Baroness Lucas of Crudwell in Wiltshire. Lady Jane Grey was a connection of the

De Grey family. The eleventh and last Earl in 1710 became the only Duke of Kent connected with the De Greys of Wrest. It was during his reign that so many improvements were made in the pleasure grounds at Wrest. The duke's granddaughter, Lady Jenima Campbell, Marchioness de Grey, and Baroness Lucas, was wedded to Philip Yorke, son of Lord Chancellor Hardwicke. Their elder daughter, Amabel, Baroness Hume, was created Countess de Grey. Their younger daughter's son became the first Earl de Grey and Baron Lucas on the death of his aunt. While visiting her at Wrest, he was allowed to build the lodges at the park entrance, and so pleased was he with their appearance that he determined to adhere to that style of architecture, and finally erected the present house to displace the one at its best in Queen Anne's reign. The present Marquis of Ripon is Earl de Grey's son, and his son's title by courtesy is Earl de Grey. The late and last Earl Cowper was a descendant of Lord Chancellor Cowper, who aided the succession of George I., and in 1710 tried the Scottish rebels. He must have been intimately acquainted with the Duke of Kent. The seventh Earl Cowper was the grandson of Earl de Grey.

Our supplementary illustration shows the Mansion as seen from the south-west. Entering the pleasure grounds by the strangers' gate, with its handsomely ornamented canopy, are seen the armorial bearings graven in stone over the gateway, now mottled by age. A fine piece of greensward is bounded on the right by a high wall, clothed to the summit by Honeysuckle and other climbing plants. A gate on the right is of wrought iron, beautifully worked (see fig. 62). This leads to the kitchen garden, that extends over six acres. Inside are very large trees of Wistaria; some of the stems are chained to the walls. The walls of this kitchen garden are furnished with fruit trees. Within the first enclosure are some Standard Pears, which have been severely pruned, with good results. A hedge of Sweet Briar grows on each side of the walk. Tomatos are largely planted in this open garden: more than one hundred plants were noticed during a recent visit on one plot. Strawberry plants are cropped but once only, and fresh stock is raised each year; the Leader is the variety chosen. Walking through the open iron gateway shown in the foreground (fig. 62), the visitor arrives in the west flower garden (see fig. 63). The flower-beds are gay in spring time with Wallflowers, Tulips, Hyacinths, and Silene, and in summer with Pelargoniums, Tagetes, Coleus, Cannas, and Campanulas. On one side is a conservatory, from the steps of which the visitor looks down upon a mass of flowers. Near the wall, in contrast to the Wistaria and other climbers, is a statue of Pomona, the goddess of fruit, with her overflowing cornucopia. In the centre of each of the larger beds are smaller figures of Cupids depicted as enwreathing themselves with flowers. The Conservatory is a small but well-stocked building, containing some large specimens of the Mandarin Orange and Camellia trees, while on the walls are trained Pelargoniums and Fuchsias. One end of the Conservatory can be seen in the supplementary illustration. It joins the residence and a doorway connects it with the morning-room,

The terrace is about 30 feet wide, and extends the whole length of the south front. It is paved with large square stones and forms a good promenade. Some ornamental and gilded rails lead to steps entering a formal garden. From the terrace is obtained a splendid view. Beyond the fountain, near which stood the old mansion, there is a rectangular canal; at the other end of

more than one hundred and twenty acres. It is from the terrace that one is able to judge of the full beauty of the place. From this spot one is able to appreciate the design of the flower-beds below. The form of the Tulip was worked out by Earl de Grey with an edging of Box, and paths of Matlock spar bring the design into prominence. At the extremities are stone figures representing the

FIG. 62.—WREST PARK: THE GATES LEADING INTO THE KITCHEN GARDEN.

this is a picturesque domed pavilion erected by the Duke of Kent, and in the distance can just be discerned on the skyline the Chiltern Hills. On the near left and right sides are elevated platforms, forming well-kept lawns under leafy Elms, and beyond are choice trees, culminating in a wilderness on each side of the canal. There are about seven miles of paths in the pleasure grounds, which embrace

elements and others the seasons, while still others in lead on stone bases are in the centres of the flower-beds. In the foreground of the picture is the Rosary, with specimens which include La France, Mme. Abel Chatenay, Maman Cochet, and Papa Gontier. The beds are bordered with Violas. Formerly the roots of the Elms near by interfered with the welfare of the Roses, but a wall was sunk

between the Elms and the Roses, the top forming a gravel walk, and the Roses have since flourished.

The grounds are studded with statuary, and the majority of the figures come from the exhibitions of 1851 and 1861. Several of these may be seen on the walk leading from the terrace steps to the fountain. Fifteen standard Portugal Laurels—the stems encased by square wooden bases covered with ivy—have been planted on either side of the broad walk; these Laurels are carefully trimmed. An Irish Juniper stands between each of these. A high Yew hedge on the left shelters an old orchard. In the centre of a circular pool is a statue of Atlas. Near this point is a splendid specimen of the Sequoia (*Wellingtonia*) gigantea, planted about 1850; it is about eighty feet high and the branches are nearly forty feet across at the base. Trees of the Copper Beech abound,

flowers. Ferns grow in luxuriance. The spring provides water for the lake, which "Capability" Brown, the celebrated landscape gardener, engaged by the Duke of Kent, altered and ornamented to form a boundary to the grounds extending nearly a mile. This in early summer is a beautiful spot, especially when the Rhododendrons are in full bloom. A few steps further is a bowling-green, with its curious house in Queen Anne style, fitted with furniture of that period. On this green the Duke met his contemporaries, and the Countess of Kent before him would enjoy a chat with her secretary or steward, Butler, the author of *Hudibras*, and the learned Selden. Parallel with the soft, velvety bowling-green is a "lover's walk," where Lime trees form an archway. Near the house stands the Orangery, which shelters during the winter the dozen Orange trees brought from Paris

the plants are watered at least once every two days.

The crop of Endive planted at the end of June is fully developed, and we are now using the leaves to blanch them. They will be sent to market in a week or ten days. They have been watered each day, but this is not done when the sun is extra hot, for if they are watered then the heart of the plants would be liable to decay. To cultivate Endive successfully, especially on manure beds, another crop, either of Cabbage Lettuce or Cauliflower, must be planted with them, for if they are grown by themselves they are liable to become drawn and to form no heart. They need an abundance of moisture at the roots to prevent the central leaves from becoming spotted.

We are now planting our last batch of Batavian Green. Although the weather is unfavourable for transplanting, the work cannot longer be delayed. We are sowing our batch of Winter Spinach. The seeds are scattered broadcast in beds 9 feet wide. Sometimes

FIG. 63.—THE WEST FLOWER GARDEN AT WREST PARK.

as do Cedars. The Tulip tree (*Liriodendron tulipifera*) is also planted here. A trained Yew, some twenty-five feet in height, is known as the Grenadier's Cap, because of its resemblance to a soldier's bearskin. To the right is a Yew hedge, which is one of the prominent features of Wrest. It is at least 350 years old, twenty-six feet wide, twenty-two feet in height, and about 480 feet in length. Two men are employed for a period of about three weeks in trimming this hedge, which, I believe, has only one equal, namely, that at Studley Royal, Lord Ripon's at in Yorkshire. Close to this hedge are the baths, which formed at one time the bathing place at Wrest. A ruined structure, mantled with Ivy, covers the actual pool, the water issuing from a chalybeate Well and flowing under the rockery (see fig. 61), which in summer, as noticed in the small illustration, is decked with

when Louis Philippe's effects were sold. In summer they make a grove at right-angles to the standard Laurels and Junipers.

The pleasure grounds and gardens are in the excellent care of Mr. George Mackinlay, who is well known to most gardeners. W. T.

NOTES FROM A "FRENCH" GARDEN.

THE fruits of the first two batches of Melons have been gathered, the barren haulms removed, and the ground hoed and well watered to promote as much as possible the growth of the Cauliflowers that were planted amongst them at the beginning of July.

The last batch of Melons planted at the end of June is doing well. The lights are kept on the frames, and ventilation is given in moderation, as the weather is somewhat dull. All unnecessary growths are promptly removed, and

they are sown in beds 4 feet wide so that they may be covered by frames and lights later in the season.

Our first batch of Lamb or Corn Lettuce has been sown, the variety being Green of Etampes. It is advisable in an old-established garden or in a sandy soil merely to hoe and rake the bed for this sowing, but in our heavy soil we are obliged to resort to digging. The germination of the seeds is rather difficult, and must be stimulated by frequent and light waterings. We have pricked off the young Cabbage Lettuces sown at the beginning of this month, 2 inches apart. All the frames from the first batches of Melons have been stacked in heaps, 15 frames high.

We are busily engaged in breaking up well-decayed manure for use when sowing and pricking off Cabbage, Cauliflower, and Cabbage, as we prefer to have everything in readiness before the sowing is commenced. *P. Aquinas, Mayfield, Essex, August 16, 1908.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, ante, pp 84-90)

(Continued from page 144.)

5. SOUTHERN COUNTIES.

SUSSEX.—Some varieties of Apples have full crops, while others are nearly bare, as also are individual trees among the bearing varieties, but none have fulfilled their early promise, as trusses of blossom fell off to a great extent, in some cases owing to the phenomenal attack of brown rot disease. Pears blossomed profusely, but set very little fruit. Plums vary, many trees of every variety are almost or quite barren, and few are fully laden with fruits. Damsons, in my case, are almost entirely devoid of fruit, nine trees out of ten being fruitless. I had a great crop of Gooseberries injured by drought, a light one of Black Currants, and a fair one of Red Currants, and now there is a good one of Raspberries. *William E. Beer, Magham Down, Hailsham.*

—The fruit crops here are good but not quite up to the average of years. Peaches and Nectarines were ruined by the snow and frost of April 21; Pears were also in bloom when snow again fell on April 24 and 26, the snow laid followed by frost. All bush fruits are good. The Strawberry crop was soon over, the weather being hot and dry; Apples are an average crop on pyramid trees in the kitchen garden; the trees are clean and making satisfactory growths. Plums on walls are good, but trees in the open are barren. *A. B. White, Paddockhurst Gardens, Crawley.*

—The fruit crops are, in general, very good. Strawberries, both early and late varieties, have been excellent; also Gooseberries and Raspberries, and the promise well both in quantity and quality, especially Brimley's seedling, Dutch Magnolia, Worcester Pearmain, Lane's Prince Albert, Cox's Orange Pippin, King of the Pippins, and Scarlet Pearmain. Plums that promise best are Cox's Emperor, Victoria, The Czar, Grand Duke and Pond's Seedling. Constant attention to root pruning I consider one of the chief points to success with trees growing in this heavy soil. *H. Langridge, Old Hall Gardens, Burgess Hill.*

—The fruit crops here are splendid, all the best varieties of Apples are so heavily cropped that severe thinning has been necessary in the case of Cox's Orange, Allington, and St. Edmund's Pippins, and these choice dessert varieties look well and more promising than last year. Pears are not so regularly cropped, but many varieties had to be thinned. There are good crops of Rasberries, Currants, Gooseberries, Strawberries, and Loganberries, and the fruits are of good quality. Cherries are good; all the trees appear robust and are making good growths. We practise much summer pruning, and this for wall trees has been a necessary this season. *H. A. Cook, The Gardens, Leonardlee, Horsham.*

WILTSHIRE.—Fruit crops generally in this neighbourhood are satisfactory. Apples are an average crop and the quality is good. Small fruits are good, with the exception of Gooseberries. These were nearly all destroyed by the late frost. Strawberries have in many places been abundant, but they suffered in their later stages from the drought. *W. Tinsley, Malmesbury.*

7. ENGLAND, N.W.

CUMBERLAND.—The fruit crops in this district in general are good. Apple trees are clean and are carrying healthy foliage. Pears are only an average crop, the bloom having suffered from frost in April. Small fruits are plentiful and good. Strawberries suffered a little from drought at the end of June and early in July. *William Scott, Eden Hall Gardens, Ingleton, R.S.O.*

—The unimproved wood, caused by last summer and autumn being wet and sunless, was the chief cause of the failure in Pears, Apples, and Apricots, as well as standard Plums. Strawberries were a splendid crop of fine fruits. Small fruits are good, excepting Gooseberries, which are very poor on some trees, but other bushes have a full crop. *J. Clark, Lealster Castle Gardens, Penrith.*

LANCAHIRE.—There was an abundance of blossom on trees of stone fruit, though much of it seemed weak and infertile; these conditions, with a low temperature at the season when the trees were in bloom, prevented a good set. Apples and Pears were very late in blooming and escaped the late frosts, so that there was a good set of fruits, but during the very dry weather in June many of them fell. *E. F. Harrison, Knowsley Gardens, Preston.*

—Apples are an abundant crop, with the exception of the late varieties, which have thinned themselves within the last fortnight to a moderate crop. Where caustic alkali solution was used as a winter dressing, insect pests have not been troublesome. Pears and Plums suffered from the very cold, low temperature of the nights of April 22 and 23, the thermometer registering 0° and 9° of frost, with a heavy fall of snow. Cherries are an average crop, the quality of the fruit being good where a plentiful supply of liquid manure was given during the last week of the winter. Small fruits, especially Raspberries, Red and Black Currants, and Loganberries, are excellent. Gooseberries, however, are very much under an average crop. Strawberries have been good in quantity and in quality. *B. Cromwell, Cleveley Gardens, Alton, Liverpool.*

—The show of Apple blossom was one of the finest I have ever seen, and the set of fruit was enormous. The hot, dry weather of the latter half of June and the first week of July caused, unfortunately, great quantities of the fruit to fall. In spite of this the crops are still heavy and very promising for fine fruits. The trees are, on the whole, very clean and healthy. Pear trees are somewhat partially cropped; some varieties, notably Beurr d'Ananias, Beurr d'Arcberg, and a few others, are bearing heavy crops, while others have none at all. This is not a good Plum district, owing, I think, to the sandy nature of the soil and the absence of lime. All small fruits are excellent crops, and fine in quality. *Ben. Ashton, Latham House Gardens, Ormskirk.*

—Everything was favourable to the setting of Apples and Pears this year, and all our kinds of fruit. The few Peach trees we have on walls had only a few weak flowers, consequently the fruits are few. Everything else may be said to be a full crop in this district, and except that caterpillars devoured some of the leaves of the Apple trees, I have not heard any other complaints in regard to the fruit crops. *W. P. Roberts, The Gardens, Curzon Hall, Preston.*

WESTMORELAND.—The fruit crops in this county are not so good as the early prospects gave promise. The wood of fruit trees and bushes failed to ripen last autumn owing to a lack of sun-shine. Nevertheless we had a promising show of blossom, but Apples, in particular, have failed to carry full crops. *H. Gibson, The Gardens, Levens Hall, Mablethorpe.*

—Late varieties of Apples are much better cropped than the early varieties, but all were full of blossom. Last year we had a very wet autumn with little sun, therefore the wood was not well ripened. This spring also was not favourable, for east winds prevailed. I have never seen better crops of Strawberries; Raspberries are also a full crop. The soil here is on the limestone. *J. Moorhaus, Dalton Hall Gardens, Burton.*

—We had every prospect of a good crop of fruit all round, but owing to the east winds in April and sharp frosts on more than one night, the crops generally are not favourable. *H. Cotton, The Lodge, Helme Dale, Kendal.*

—Apples are plentiful, the varieties Strling Castle, Lane's Prince Albert, Annie Elizabeth, Keswick Codlin, Warner's King, and New Northern Grown being heavy crops. Pears are few, likewise Plums and Cherries. Strawberries have been a heavy crop, the best for many years, especially Royal Sovereign. Kenish Favourite promises well. *H. A. Miller, Underley Gardens, Kirby Lonsdale.*

8. ENGLAND, S.W.

CORNWALL.—Apricot and Plum trees set enormous crops, but frosts killed all the young fruit. This being a late district, the bulk of the Peach blossom opened ripely, only the very early flowers being damaged, but cold weather

later caused many of the young fruits to drop and also ruined what might have otherwise been a plentiful Apple year. *A. C. Bartlett, Pen-carrow Gardens, Bodmin.*

DEVONSHIRE.—Apples and Pears were much injured by the drought throughout June. Apricots, Peaches and Nectarines suffered much from cold, dry weather and late May frosts. *Andrew Hope, Prospect Park, Exeter.*

—It is many years since we witnessed such a wealth of blossom on all kinds of fruit trees, especially Apples. These fruits and Plums are the two most irregular crops of the season. Doubtless the cold winds and frosty nights accounted for the partial failure of the Plum crop, and ill-ripened wood must be the cause of the thin Apple crop. Strawberries and bush fruits have been produced in abundance. *James Mayne, Bilton Gardens, Budleigh Salterton.*

—Gooseberries are a small crop, but Currants and Raspberries are very good. The earliest fruits of Strawberries were also good, but later berries suffered from drought. *E. E. Bristow, Castle Hill Gardens, S. Molton.*

—There was an abundance of blossom on fruit trees, but the cold, wintry weather at the time Pears and Plums were in bloom is responsible for the scarcity of these fruits. A light rainfall up to June was followed by drought, and these conditions have caused Apples and Cherries, especially Morellos, to fall from the trees. The drought has also affected Peaches on outside walls. *T. H. Slade, Poltimore Gardens, Exeter.*

—The fruit crops generally are plentiful and good. All small fruits are abundant and of fine quality. Apples generally are a good crop, and up to the present the trees are very clean. Pears are rather scarce; they apparently set well and promised a heavy crop, but after a spell of cold weather they dropped badly. Of Plums we have none, and Apricots are a light crop. Peaches and Nectarines are good crops, and the fruits promise to finish well. *J. Coady, Killiton Gardens, Exeter.*

—The fruit crops in this district are, generally, very good. Apples are a heavy crop and of good quality, especially on pyramid and bush trees, the fruits having required a severe thinning. The fruits in orchards are also good, but the trees are less regularly cropped. Pears are a light crop, but of good quality. Peach trees suffered early in the season from blight, but the shoots are now clear of pests. Strawberries were a heavy crop, but the drought somewhat checked the late fruits. The Gooseberry crop was rather a light one, but Raspberries and Currants are very fine. Our soil is a light loam on waterstone. *Geo. Baker, Memland Hall Gardens.*

GLoucestershire.—Apple trees, in spite of a remarkable show of bloom, are sparsely cropped. Some of the trees, however, are carrying good crops, viz., Frogmore Prolific, Tower of Glamis, Lane's Prince Albert, Ecklinville Seedling, and Keswick Codlin. Caterpillars injured some of the trees, notwithstanding they were sprayed with the alkali wash in the middle of February. Dessert Cherries set very imperfectly, and Morellos are fairly cropped. Gooseberries are a failure owing to 6° frost on the night of April 23, when the bushes were in full bloom; on April 24 they were covered with snow. Black Currants are only a quarter of a crop; hitherto these fruits have always been abundant. Strawberries have been very abundant and of excellent quality. *John Banting, Tortworth Gardens, Falfield.*

—Pears are very promising, the trees having been syringed each evening during the hot weather of June. Apricots are a failure, but Peaches and Nectarines are fair crops. Plums a moderate crop, and Cherries a good one. Strawberries have been abundant and of good flavour, lasting much longer than usual. Raspberries are abundant and good, also Red Currants, but Black Currants are a failure. *F. C. Wallon, Stunley Park Gardens, Stroud.*

—Apples are an average crop. Apricot trees, following a heavy crop last year, bore very few blossoms. Plums are an average crop, but Greengages and Damsons are scarce, the birds having destroyed the fruit-buds. Peaches and Nectarines are scarce. Gooseberries suffered from severe frost. Raspberries are a good crop, also Currants. Strawberries were

abundant and of good quality. Cherries are plentiful, especially Morellos. *A. Chapman, Westonbirt Gardens, Tetbury.*

—The flowering season of nardy fruits was all that could be wished for, but in some cases severe weather, which was experienced late in the season, ruined the crops, especially on trees in exposed situations. Apricots appear to have suffered most. Gooseberries are scarce in some places. On the whole we have an average crop of fruits of good quality. *Thos. Cooper, Sedbury Park Gardens, Chipping.*

—All fruit trees gave promise of good crops. I never remember having seen Apple and Pear trees so full of flower, but frost at the end of April and May ruined all the expanded blossoms. Strawberries have been a record crop; the berries were of good flavour, but not quite so large as usual owing to the dry weather. Red Currants are a full crop, but of Black Currants we have only half the usual quantity. *W. H. Berry, Highnam Gardens.*

HEREFORDSHIRE.—Strawberries were very good, but the rain came too late to develop more than a good average crop. We had 14° of frost on April 23 and 10° on the 24th of that month, and this ruined a grand lot of well-set Peaches, Nectarines, and Apricots, despite extra protection given. Raspberries are very satisfactory, but Gooseberries are not a large crop. Red and White Currants are of good quality. Our soil is a cold, heavy clay. Generally there is a good crop of Damsons in this district. *Thos. Watkins, Newport Hall Gardens, Eardisley, R.S.O.*

—The Apple crop is a good one, and the trees are very healthy; thinning the fruits had to be resorted to owing to the very heavy crops. Pears are few; also Plums on walls, owing to the cold weather of April when the trees were in full bloom. Bush Plum trees are carrying a good crop; those were not in bloom during the severe weather. Apricots, however, were all destroyed. Small fruits suffered from the same cause; Gooseberry bushes were denuded of their fruit, and Currants were considerably thinned. Raspberries are a moderate crop, but the fruits suffered severely during hot, dry weather. Strawberries have been good. *Thos. Spencer, Goodrich Court Gardens, Ross.*

MONMOUTHSHIRE.—Apples are abundant and good, the trees being clean and healthy. Pears set well and promise a splendid crop, but the Pear midge is answerable for many of these fruits falling. Peaches and Nectarines are not as plentiful as usual, although there is a fair crop of fine fruit on slightly protected trees. Fig trees on walls promise a good crop of fruits, but on trees in the open they are a failure. Strawberries have given an enormous crop of well-flavoured fruits, the dry weather allowing them to ripen without decaying. The partial failure of the Plum crop is due to the disastrous frost and wet weather experienced during the time the trees were in bloom. The same remark applies to Gooseberries. Raspberries and Currants have yielded heavy crops of fine fruits. *W. F. Wood, Llanyfrocha Grange Gardens, Caerleon.*

—All kinds of fruit trees blossomed abundantly, but the continuance of low temperatures and the 9° of frost, accompanied by snow, on April 23, during the flowering season of Plums and Pears, did much to spoil the favourable prospects. Of the variety *Bellevue* carries a full crop, and of Peaches *Belvedere* is the only variety that has a full crop. Gooseberries and Black Currants are thinly cropped owing to the frost. Strawberries were remarkably prolific, and the fruits were of fine quality. Apples are good in every respect; some kinds have had to be severely thinned of their fruits. Kitchen varieties are generally more heavily laden than are dessert varieties. *T. Coomber, The Healds Gardens, Monmouth.*

—The Apple crop generally in South Monmouthshire promises to be much above the average; the quality of the fruit is good, and the trees are free from aphids. Pears are an average crop, and the trees are very free from blight. Stone fruits, with the exception of Plums, are almost a failure, and the same remark applies to Gooseberries and Currants. This was caused by the severe frost on April 23. The recent rains have been very beneficial to all fruits, and they have fallen in sufficient quantity

to reach even the roots of the trees in grass orchards. *John Basham, Fair Oak Nurseries, Basildon, Newport.*

SOMERSET.—There was an exceedingly good show of blossom on all kinds of fruit trees in this district, but the persistent east winds and low temperatures, together with a heavy snow-storm and sharp frost on April 25, ruined the promise of good crops of Apricots, Plums, Pears, Cherries, and Gooseberries. Apples in the orchards have suffered from drought, but there are good crops in cultivated gardens. *George Shawley, Halswell Park Gardens, Bridgewater.*

—Apples promise a very heavy crop. At the time the trees were in flower they were a lovely sight, some orchards being a mass of bloom. Most kinds of fruit trees were later in blooming than during the past few seasons. Apricots are practically a failure, owing, presumably, to the heavy crops of last year. Small fruits of all kinds, especially Gooseberries, Red Currants, and Raspberries, are a heavy crop and of good quality. On the night of April 23 sleet fell, and on the morning of the 24th of that month we registered 9° of frost, this being followed by a heavy fall of snow. Plums then in flower were badly injured. Untrained Fig trees are carrying heavy crops of fruit. *Geo. H. Heald, The Gardens, Kingsdon Manor, Taunton.*

—There was an excellent show of blossom on all fruit trees and bushes this spring, and most of these have set very well, but from many places complaints are general as to the failure of the Gooseberry crop. This is due to a sharp frost occurring when the bushes were in bloom, although here and in one other garden which I have visited the crop of this fruit is quite up to an average one in both quantity and quality. Peaches and Nectarines on unprotected trees were also ruined. Strawberries set very well, and the plants having been copiously watered have yielded a heavy crop. *A. Skelton, The Gardens, Ford's Abbey, Chard.*

WORCESTERSHIRE.—What at one time promised to be a full crop of fruits was entirely spoiled by the frosts at the latter end of April. The Gooseberry crop was destroyed, also the larger varieties of Black and Red Currants. Amongst Black Currants the variety *Ogden's Black* was not injured in the least, the fruit now being very fine. We never had a finer show of Apple blossom, but whilst some varieties are heavily laden, others are very thinly cropped. *A. Young, Watley Court Gardens, Worcester.*

—Apples and Strawberries are the most satisfactory crops of hardy fruit crops. We experienced sleet and snow, followed by 10° of frost on April 24, and even before it was dark the leaves and blossoms were frozen together and were as brittle as glass. Pears, Plums, and bush fruits were then in full flower and suffered greatly. It was distressing to find oneself unable to cope with such a visitation, and to see the work of a whole season ruined. *William Cramp, Madresfield Court Gardens, Malvern.*

(To be continued.)

FOR STRY AT THE HUNGARIAN EXHIBITION.

IN the earlier notice of the exhibition at Earl's Court (see p. 41), the various products of the vineyard, the farm, orchard, and garden were remarked upon; but the present one is concerned with forestry. Trees are not cultivated in Hungary as ornamental objects on an estate, or as merely forming roosting perches for pheasants, but for commercial uses or for furnishing fuel for the inhabitants; thus they afford a means of livelihood for a large section of the peasantry. Very little timber is imported from abroad, and only such kinds as are used in cabinet work and the finer kinds of furniture.

But few of the objects shown at the exhibition appeal to the visitor, unless he be conversant with, or is an expert in, woodcraft, or a dealer in timber, very few of the exhibits being of a nature to attract the eye; and yet in all this sombre-looking material and the primitive tools

and appliances there is much that shows the great extent of the various industries connected with the planting of forests and woods, and the importance of the cultivation of timber trees to the community as a whole. It furnishes the main source of the fuel consumed, for coal is a scarce commodity in districts far from the Carpathian Mountains; it finds employment for a large number of the inhabitants all the year round in planting, felling, barking, and in the preparation of timber for the innumerable purposes to which it is put in a civilized community.

The Royal Hungarian Woods and Forest Office, Lotosovar, have numerous exhibits, and the visitor will note the fact in the raw Oak timber from Orsova that the flint and steel method of obtaining fire is still in use in parts of the country. Alongside of this timber is a large bundle of splints (stems) for the making of matches, a hint that the era of tinder and flint and steel was about to come to an end. These match splints are made from some species of *Conifer*, the trees being grown closely together, so that no knots shall appear in the wood to spoil the simple and cause waste in cutting up. This Forest Office shows implements for stripping bark for tanning leather, tools employed in felling and working timber; broad axes, adzes, bill-hooks, &c. There is shown an analysis of the bark of the Tanner's or Turkey Oak (*Quercus Cerris*) and of the Hungarian Oak (*Q. panonica*), this last from the R. H. Forest Office at Lipka. There were noted several exhibits unfamiliar to an Englishman, namely, shingles, grooved and ungrooved, for roofing purposes, and made from Pinewood. These shingle roofs are much in use in Hungary and to a less extent in Austria; they last a score or more years, are cheap, easily repaired, and withstand the severe hailstorms common in that country to a better degree than this slates. There are diagrams of methods of afforestation, part of the area to be planted being under farm crops as a preliminary course of treatment. This is, as I know, a common practice, the forest owner asking, as a rule, no rent for the use of the land for two or three years. By this method, which is of mutual benefit to owner and farmer or cottier, the land reverts to its original use in a clean condition, free from noxious weeds and deeply cultivated, besides being freed from the stumps and bigger roots of the trees that formed its previous crop. Shingles formed of Beech and ungrooved are exhibited from the R. F. Office of Bustyabaza, besides wheel spokes of Locust tree wood (*Gleditsia triacanthos*), spokes of the common Ash, wheel hubs of Turkey Oak, and sections of impregnated and non-impregnated Beechwood railway sleepers. In the mountains and hills, wood shires, with and without water, are used to transport heavy timber from the higher ground where horse traction is impossible, and models of these are exhibited. These are formed of slender tree trunks, barked and laid close together so as to form a channel 3 to 4 feet in depth and 5 to 6 feet in width. Such appliances are commonly used for firewood transportation. A model of a snow shelter or refuge is shown; it has a gallery formed round the entire upper storey, which projects over the lower storey, forming a gallery or passage some 6 feet in width round the latter. These galleries being closed at the sides and ends would provide shelter for a large number of people. A coloured illustration is displayed of the Royal Experiment Station of Szobed, and likewise a model in wood of the headquarters of a forest ranger, a most commodious-looking dwelling, with all its various appurtenances. There are likewise specimens of horse shoes for use upon bare, curious things with iron rings riveted on the face of the shoes, instead of studs as with us; of ordinary horse saws, water driven; also of hand saws working perpendicularly on a sledge, and on the ground instead of in a pit, the motive power being obtained by an over-rot

wheel; and of a bark crusher similarly worked by water power. There are models of methods of charcoal burning, showing a deeply-notched tree stem instead of a ladder of rungs, used in ascending a charcoal mound in process of charring. The entire process of cellulose making and its formation into sheets is shown in another model; as also the ground-up material at various stages of manufacture. Examples of good and bad tree planting in real Oak saplings form a practical lesson in planting. There may be seen the common basketwork wagons used by charcoal burners for the carriage of charcoal, for use on wheels or sledges, drawn, as are nearly all wagons in Hungary, by a pair of trace horses; likewise a woodman's hut of a round shape and pointed at the top, with a roof of shingles, and a penthouse over the entrance. A large view shows the Royal High School of Forestry at Selmec, by Banya. At Kiszlybe there is established a forest school under the management of the High School. It lies in the parish of Topetak; latitude, 48°27' to 48°28'; longitude, meridian of Ferrol, 36°36' to 36°38' east; 450 feet to 670 feet above sea level. The substratum is trachite, with a little basalt. The soil, of medium depth, is a sandy clay. The rotary period of the forest at this place is 100 years, and the exploitation of the forest is provided for by gradual renewal after felling the trees and clearing the area. This work is carried out partially by natural and partly by artificial means, special attention being paid to the planting of Oak, Poplar, white Pine, and other valuable species of native and exotic trees.

Tools used in forestry are shown in great variety, including the heavy hoes (known as "grafts" in Kent), and wooden and iron rakes in all sizes. The specimens of Oak, Maple, Ash, Elm, Silver Fir, and Common Beech timber are extremely fine, some of them having boles of 3 to 4 feet in diameter. From an illustrated handbook which is being freely distributed, it is interesting to learn that notwithstanding the enormous area of forests in Hungary (more than 35,000 square miles), the Government is extending and renewing them on a large scale. In the State forest-nurseries a stock of two hundred million young trees is maintained, from which over forty millions are transferred to the State forests annually, besides ten to twelve millions sold at a low rate to private persons. In addition the Hungarian State possesses many fruit nurseries, from which about four million young trees are yearly distributed to communal authorities and others. *P. M.*

KEW NOTES.

THE GREENHOUSE.

THERE are many interesting and beautiful subjects flowering in this house at the present time. The Giant Balsam, *Impatiens Oliveri*, from British Central Africa, which was the subject of a Supplementary Illustration in the *Gardener's Chronicle* for October 27, 1906, has become too large for its tub, and has, therefore, been planted out in the centre of the house, where it is now growing freely. Although it cannot be claimed for the plant that the inflorescences make a brilliant show, there are always flowers on the plant, a characteristic which cannot be claimed for many of the other greenhouse subjects. Arranged amongst a group of the "Chimney Campanula," *C. pyramidalis*, are some 25 well-flowered pot-plants of *Watsonia Merriana* var. *O'Brienii*, or, as it is better known in gardens, *W. Ardeni*. The bulbs were potted early in April, four being placed in a 7-inch pot. They were grown in a cold frame till the flower spikes were well advanced, when it became necessary, owing to their height, to transfer the plants to a cool greenhouse. Most of the flower spikes are 5 feet in height. Two tall-growing *Calce-*

arias, valuable for large show houses, are *C. Buralbaei* and *C. integrifolia*. Both have yellow-coloured flowers (the latter is the more compact in habit, but its flowers are smaller and are arranged closely together in the panicles). Both species have been flowering in this house since early summer.

The genus *Begonia* is largely represented, including the tall-growing species *B. coccinea*, *B. chinosepala*, *B. fuchsoides* and the varieties *B. nitida alba*, *B. President Carnot*, and *B. Luzerna*, the latter a hybrid raised on the Continent. It has very similar growth to *B. President Carnot*, but with deeper coloured flowers and shining, dark-green foliage. On the side stages, in addition to single, double, and fringed tuberous-rooting varieties, are plants of *B. Corleille de Feu*, a variety in the way of *B. fuchsoides*, which was one of its parents. It is, however, of dwarf habit and fringed flowered than *B. fuchsoides*, and the flowers are lighter in colour. *B. Evassiana*, *B. Davisi*, *B. Pearcei*, *B. Bertini*, *B. Triomphe de Lorraine*, a double semperflorens variety with bronze-tinted foliage, and *B. Gloire de Chatelaine* are all represented by small or large groups of plants. The last-named variety is dwarf, compact, floriferous, and belongs to the semperflorens type; it is of recent introduction, and has rich, rose-coloured blossoms.

The rich scarlet flowers and handsome foliage of *Clerodendron litalax* are prominent all around the greenhouse. The plants are about 14 months old, being raised from seeds. They were transferred to this show house from a warmer house when the first flowers were expanding in June. The light, graceful racemes of *Francoa* rising amongst the other flowering plants are very ornamental. *F. ramosa*, white, and *F. sonchifolia*, pink, are the two species utilised. The variegated variety of the giant Tobacco, *Nicotiana tomentosa* (syn. *colossea*) is represented by two particularly handsome and striking specimens. The species of *Kalanchoe*, *K. flammula*, and the two hybrids *K. × kewensis* and *K. × felthamensis* are showy and valuable, as they continue in flower for a long time.

The introductions to gardens of the dwarf early-flowering variety of *Salvia splendens*, named *Glorie of Zurich*, is welcome. The plants at Kew have been on show for a period of three months, and they are still a blaze of scarlet flowers. The *Statice* or Sea Lavenders are other plants noted for the long time they flowers last; *S. brassicifolia*, *S. macrophylla* and *S. prolusa* are all worthy of culture. A pretty *Pyrethrum*-like plant with small double white flowers, named *Matricaria mondana*, is a useful decorative plant. I have not seen this in other gardens, but it is worthy of inclusion in a greenhouse. *Jacaranda mimosifolia*, also known as *J. ovalifolia*, is not often seen in flower. It belongs to the natural order Bignoniaceae, and the lavender-blue flowers are produced in terminal panicles, the shape and size of the individual blossoms resembling those of *Tecoma Smithii*. Our plants were raised from seeds sown in 1906, and were stood in the open under a hot south wall during the summer of 1907. In the winter the foliage was ornamental, and the plants were interspersed amongst flowering plants in a cool house.

The white-flowered *Campanula Tridatii* is a distinct Bell-flower. It has pendulous flowers and rich dark-green foliage that are appreciated in a greenhouse, either alone or arranged as a groundwork for taller-growing subjects. The introduction of a set of hybrids of *Impatiens Holstii* with flowers of some six or seven distinct shades of colour has given an added value to this plant. The offsprings are dwarf in habit and particularly free in flowering. *Fuchsia Abou-Hifman* is usually recommended as a dwarf bedding variety. Grown here in 6-inch pots, the bushy plants, 6 inches to 9 inches in height, are covered with blossoms. It has a light red calyx and white corolla. *D. D.*

FLORISTS' FLOWERS.

THE VIOLA AND PANSY.

Many persons who have not the convenience of a glasshouse or frame manage to propagate these plants by inserting cuttings in the open garden, shading and protecting them from sun and drying winds until they are rooted. In order to obtain the best results it is well to have glass frames in which to propagate the plants and protect them from severe weather. Violas are harder than Pansies, but the method of propagation is similar. In the Pansy more than in the Viola, the main flowering stems are hollow, and these should not be used as slips or cuttings, but the best shoots for rooting are the numerous small growths produced at this time of the year. These are pulled out with the fingers, and, generally, small rootlets are attached to their base. Some fine sandy soil should be placed in the frame to the depth of about 3 inches, and into this the cuttings should be inserted about 3 inches asunder. If the lights are merely tilted a little at the back of the frame the cuttings soon become established, and the light may be drawn off both night and day, except when the weather is wet. Some of the plants may be kept under glass for spring planting, and others may be planted out early in October to flower as early in the spring as the weather will permit them. As soon as weather permits, a second planting may be made in spring, and this batch of plants will flower all through the season, and in some districts if the weather is mild all through the winter. Good soil is essential to success in the culture of these plants, and it should be worked to the depth of 18 inches and well manured. The blooms of the Pansy more than those of the Viola soon fall off in quality after the first rich display. The best treatment is to pick the flowers off, top-dress the plants with a rich compost, and peg the growths into it. Seedlings are harder than plants raised from cuttings. *J. Douglas.*

MARKET GARDENING.

THE MARSHLAND BULB SEASON.

EVERYTHING was backward at the start of the growing season, but copious rains and more than a usual amount of sunshine have developed the growths of the bulbs. The weather has been glorious for lifting the bulbs, which is still being done between the intervals of fruit picking. On the 8th inst. we lifted a large breadth of *Bouton d'Or Tulip*, a variety which develops highly-coloured flowers on this salty soil.

Narcissus is a wonderful crop. On a large acreage of these plants, five years old, specimens have been lifted with as many as two dozen bulbs in a clump. The top soil, in which are bulbs intended for furnishing a supply of flowers (10,000 boxes of flowers were sent to market last season), is now being top-ploughed, and the plough is followed by the horse harrow. Dry weather is favourable for these operations.

Coming to work on this bulb farm as a strange hand (though I have for years been a visitor), the system of culture was a revelation to me, and showed what can be done in this country in bulb-growing on suitable land. The silt is land reclaimed from the river's bed (really an arm of the Wash), and except for being weedy is just what the bulbs enjoy. Such land is always in a workable condition, the only drawback being the weeds, which are difficult to exterminate by hoeing, especially in wet weather. The bulbs are grown beneath belts of fruit trees and bushes, there being rows of Apple trees, with bruses between. The trees protect the bulb beds from the effects of both winds and frosts. *Stephen Castle, Wisbech.*

ARCTOSTAPHYLOS MANZANITA.

The genus *Arctostaphylos* is represented in the British flora by two species, *A. alpina* and *A. Uva-ursi*. Both are prostrate shrubs with evergreen leaves and pink flowers. These, however, are very different plants from *A. Manzanita*, which is one of a number of upright, shrubby species natives of California. When young it is rather tender, but after attaining four or five years of age, the plant becomes capable of withstanding ordinary winters in the neighbourhood of London without injury. In some respects, especially in the wood and bark, this species resembles a dwarf-growing *Arbutus*. The leaves are evergreen, thick, and somewhat fleshy, broadly oval in shape, 1½ to 2 inches long and 1¼ inches wide. When young they are

plant flowers in spring, and its novel and pretty appearance attracts considerable attention amongst surrounding shrubs. The practice obtains at Kew of planting these and other shrubs, which are slightly tender whilst young, amongst tall-growing *Ericas* for protection. H. D.

THE FERNERY.

FERN HUNTING IN DEVONSHIRE.

As our British Fern literature contains little regarding the actual experiences of Fern hunting expeditions, perhaps I may be permitted to remedy the deficiency to a small extent by a record of a few days spent in that pursuit in the Axminster district, where the Axminster

result has been so far disappointing that the number of species falls very far short of those to be found elsewhere in Devon, say, about Barnstaple, the search in point of fact being almost entirely confined to *Polystichum angulare* and *Scolopendrium vulgare*. These two species are abundant almost everywhere in the heales and on the banks which enclose the lanes. The Lady Fern only crops up here and there in moist places. *Polystichum aculeatum* occasionally shows itself. *Polypodium vulgare* is fairly plentiful in places, and *Asplenium Adiantum-nigrum* also; *A. Trichomanes* and *A. Ruta muraria* turn up now and then on old walls, but, unfortunately for the Fern hunter, all the old walls hereabouts are kept in such good repair, either recently pointed or whitewashed,

FIG. 64.—ARCTOSTAPHYLOS MANZANITA.

rather glaucous, but afterwards become bright green. The flowers are borne in terminal panicles and are of deep pink colour. The buds are produced in autumn, and the flowers commence to open late in February, being at their best during the latter part of March and early in April. Like other members of the *Ericaceae*, this plant requires soil free from lime, and thrives most satisfactorily in light, sweet, sandy soil to which a little peat has been added. Propagation is effected by means of imported seeds, and it is a good plan to keep young plants in pots until they can be finally planted into sheltered, permanent quarters. At Kew a good bushy

plumose Lady Fern, found in 1860, formed one incentive to my choice of locality, as that Fern was the progenitor of my "superbum" section of plumose varieties of that species, which, crested and uncrested, possess such delicate beauty. Another incentive was the fact that a visit could be made to Mr. Moley, one of the surviving pioneers of the cult, who is credited with the discovery of about 600 wild varietal forms. Taking up my quarters in Colyton, in company part of the time with another Fern enthusiast, Mr. Cranfield, of Enfield, a fair number of miles of road and lane sides have been carefully explored. The

that while walls form an ideal hunting ground in many parts when left alone, they are all but barren in this locality. The season also presented its drawbacks, there having been practically no rain for two months, so that the Ferns in most places were starved and forlorn-looking, while another drawback is the hedge cutter, whose ruthless sickle had mown the Ferns by the wayside for miles. On the other hand, in other spots, it was obvious that even this drastic procedure is not an unalloyed evil, since where it is not done the grasses, nettles, and other weeds, and rank vegetative growth generally are apt to overgrow even the Ferns and, at any rate,

hide them from view or draw them out of all form. With these preliminary remarks, which promise little success, it is nevertheless gratifying to record a fair number of "finds." Among the Hartingtons I have found *Scolopendrium v. muricatum*, the surface covered with exserted growths like the crested *Bogaios*; *S. v. variegatum*, light yellow striped with green; *S. v. undulatum*, with waved fronds approaching frills; *S. v. contractum*, in which half the frond is narrowed, and the contracted part prettily frilled; *S. v. latum*, with extremely broad fronds 4½ inches wide and only about a foot long, found side by side with normal plants of half the width and twice the length; *S. v. marginato lobatum* having marginate and digitate tips; and *S. v. marginatum*, the edges of the fronds crenate with dorsal ridges round the indentations. In connection with this species we acquired no fewer than four forms of the rarely-found crispum or frilled section, but only vicariously. In a cottage window two very pretty dwarf crispums, so neat in appearance that we ventured to knock and enquire about them, since as is generally the case where Ferns are plentiful, it is a rare thing to see a variety treated as a pot plant. The lady, Miss K. White, informed us that she had found both by chance, noting an unusually pretty frond by the wayside, and to my delight brought forward a third gem, with exceptionally thin fronds and a pronounced sagittate or arrow-shaped base. One of the other two we found was inclined to creasing. Explaining who we were, and the plants bearing offsets, we arranged an exchange and bore off our prizes. Before parting, Miss White told us we ought to see another variety found by a neighbour, Mrs. Edwards, in a similar chance way, and proceeding thither, we found a magnificent fertile crispum, quite distinct, which we were informed was beautifully tasselled some seasons. It is distinguished by some of the fronds being evenly contracted for some inches into narrow, thickened frills. The nearest approach to it is *S. v. crispum Drummondiae* in general habit, but it is not frimbriated like that variety. Again, we retired with specimens due to the generosity of the finder, and were naturally much struck by the singularity of the fact that four such gems should have fallen by pure chance to the lot of two ladies who make no claim to be Fern huntresses at all or to know anything about the culture. To return now to our own finds, my friend found *P. angulare grandidens*, with contracted pinnae and pinnules, and subsequently I found other specimens on different hills. I also found a thoroughly crested variety of *P. angulare*, but with such minute tassels that my success is rather a joke. *P. angulare parviceps* is all I can call it. In this species, however, I have acquired a form of extreme interest, as will be seen. Noting a peculiarity in a single large frond peeping out from a hedge bottom, I examined it, and found a fine decomposite variety, in which the normal unfrilled pinnules were stalked, and greatly lengthened, pinnate at the base and pinnatifid to the tips, and of lustrous texture. While examining this frond, I noticed an adjacent one of an extraordinary type; the tip had been destroyed, but the remaining two-thirds of the large frond bore two rows of pinnae similarly divided to the other frond, but all without exception were truncate, terminating squarely with the midrib continuing for half-an-inch as a translucent thorn, a point that it was really a transverse part and not a damaged tip. Examining the first frond, I found the pinnae at the base, for about a third of the frond similarly truncate, and what I had assumed to be a damaged tip proved also to bear the excurrent midrib straight as I am aware, such a form is unparalleled, but the most remarkable feature from a morphological point of view has yet to be mentioned. After extracting the plant from the hedge bottom—a work of great difficulty—I proceeded

to clear away the debris of old fronds attached to it, when, to my amazement, I found five or six dead and shrivelled but unmistakably normal fronds of the commonest small pinnuled form of *P. angulare* attached to it and representing the growth of last year. This fact is beyond all doubt, and we have consequently here a case where a purely normal long-established Fern has suddenly assumed not merely one new feature but several, viz., difference of texture, of dissection and of terminal growth. It of course remains to be seen whether new growth under culture will revert or retain the new type, but, fortunately, it is profusely fertile, and I have gathered ripe spores from the entirely truncate frond. These I shall sow with care, and shall be very surprised indeed if spores from such a source do not reproduce the variety rather than the type. I have dealt with this find at some length, since I believe the case is unique. I close the record of this species with a fine form of *P. angulare revolvens*, with fronds rolled almost into tubes. Finally, I have on my list a form of the common Polypody with distinctly variegated fronds, pure white and green. The white is not due to insect action, as it is clearly visible in the young uncalled and quite healthy fronds, and there was a whole colony of it. *P. vulgare bündelium* completes my record so far. *Chas. T. Drury, F.M.H.*

P.S.—Subsequent to writing the above record on the spot, I found *Scolopendrium vulgare transverso lobatum* with crossed crests, and a very fine form of *Polypodium vulgare* with the pinnae bifid and trifid, and rolled inwards so as to form a bunched centre to the frond. In all, I brought home 18 varieties of interest. *C. T. D.*

The Week's Work.

THE FLOWER GARDEN.

By W. J. H. GARDNER to Lady WASTAGE, Lechlair Park, Berkshire.

Rose cuttings.—Shoots, 9 to 12 inches in length, of strong-growing varieties should now be inserted at a depth of about 6 inches. Do not remove any of the buds, and if possible the cutting should be taken with a portion of the old wood at the "heel." A shoot from which a flower has recently been cut is very suitable for rooting, after the lower leaves are removed and the heel of old wood trimmed. The soil in which the cuttings are inserted should be of a sandy nature. Good results are obtained by the use of pots, provided they are deep enough to allow a considerable portion of the cutting to be inserted. The cutting should rest upon a firm base, and when planting is finished be well watered. When pots are used, a gentle bottom heat will be found to be an advantage, for the extra warmth will cause roots to form readily. Rose cuttings will also root readily in cold frames and in the open ground. With care and attention the majority of the cuttings will form roots and in the following spring will start freely into growth, but it is well to defer shifting them until the following autumn. Tender varieties, including Tea Roses, may be rooted in the same manner, but the protection of a cold frame is necessary during the winter months. In some instances Roses on their own roots make comparatively little growth for some time, but all will be considered if they compare very favourably with budded plants.

Winter sowing.—The Snapdragon, as a half-hardy annual, is worthy of a place in every garden. The plants require constant attention in the removal of their seed pods, and must never be allowed to suffer from lack of water at their roots. If seeds are sown now or during September or early plants will be obtained for a second flowering. They should be given the protection of a cold frame during the winter months. By sowing more than one batch of seeds at intervals, the last in February, the flowering season will be prolonged and a succession of blooms be had until the plants are cut down by frost. The choicest varieties can be propagated from cuttings inserted any time between now and the end of September. The best

short, plump, flowerless shoots and insert them in sandy soil in a cold frame or hand light. A further supply of cuttings will be furnished by the young growths these cuttings will make early in spring, when they will root readily if inserted in gentle warmth.

THE ORCHID HOUSES.

By H. G. ALFAXBER, Orchard Grower to Lt.-Col. G. L. Holford, C.V.O., C.B.E., Westonbirt, Gloucestershire.

Subralia.—This genus contains members with very handsome flowers, viz., the species *S. macrantha*, *S. leucoxantha*, *S. Holfordii*, *S. xantholeuca*, *S. Lucasiana*, *S. macrantha Keatsiana*, *S. Sanderiana*, and the hybrids *S. Veitchii*, *S. Amesiana*, *S. Wigamiae*, &c. All are strong-growing evergreen terrestrial plants, free in flowering and ornamental all seasons of the year. I find *Subralias* thrive best when cultivated in an intermediate temperature. They need plenty of sunlight and fresh air. Thus treated, they form strong healthy shoots which flower satisfactorily during the summer months. *Subralias* are always in more or less active growth, and their large, fleshy roots soon fill the receptacles in which they are grown, thus causing the soil to dry very quickly; because of this, they require great attention in the matter of watering. During the growing season root-bound plants need a liberal supply of water, with an occasional dose of weak manure water made from farmyard manure; especially is this stimulant needful when the new growths are nearing completion in the spring. At no season should the soil in the pots be allowed to become dust dry, as a lack of moisture at the roots affect the leaves, causing many to drop. Thrips and red spider are sometimes troublesome to these plants, but if the syringing is used freely, weather permitting, about the foliage daily, little difficulty will be found in combating these pests.

Repotting.—Most of the *Subralias* have ceased flowering, and it is a suitable time to attend to their repotting. They should be examined and have some of the old flowering growths removed, cutting them away close to the roots. This will allow the young growths that are now forming more room to develop, and will admit light and air to them, especially in the case of large specimens growing in tubs. Plants that are root-bound should be shifted into larger receptacles, if big specimens are desired. Any that are considered to be too large can be divided. In performing the latter operation, it will be found a difficult matter to separate the large, fleshy roots without injuring them, but care must be taken to preserve as many of them intact as possible. After shaking the loose material from the divided parts, cut off cleanly all roots that are bruised just above the point where they are broken. The divided portions should then be put in pots just large enough to accommodate them. The receptacles, whether pots or teakwood tubs, should be well provided with material for drainage. The potting compost should consist of a mixture of two-fifths turfy loam, two-fifths turfy peat, and one-fifth Sphagnum-moss, with sufficient gritty material to keep it porous. Use the potting materials in a rough state, and make them moderately firm about the roots. The surface of the compost should be left about an inch below the rim of the pot and the crown of the plant on a level with the surface of the soil. These *Subralias* need the usual care afforded well-potted plants in respect to watering.

THE HARDY FRUIT GARDEN.

By F. J. JONES, Gardener to The Downey Lav, Nettleham, near North York, Yorkshire.

Fruit gathering.—The earliest varieties of Apples and Pears are best gathered before they are dead ripe, but only by a knowledge of the different varieties, and by using careful judgment they be sent to the table in their best condition. These early varieties quickly lose their flavour and become mealy, and more especially those growing against walls in hot and light soils. The fruit should be examined frequently when they are cool and dry in order to gather those which are ripe. Most mid-season and late varieties of Apples and Pears improve in quality and keep better if they are allowed

to hang until they are quite ripe, especially the latest varieties. Birds are troublesome this season, and all the best fruits should be protected from them. It is easy to protect fruit on wall trees, but those on bushes and standards are more difficult to guard. Wasps, too, are very troublesome, and efforts should be made to destroy them in their nests with cyanide of potassium. Wide-mouthed bottles containing sweetened beer placed amongst the trees will catch a large number of this pest, but it is a matter of opinion whether their presence does not attract larger numbers to the trees. The bottles need to be emptied at short intervals and fresh bait placed in them. The finest varieties of Plums should be protected with hexagon netting or some other material as soon as the fruits change colour.

Watering.—The rainfall during the past few weeks has been irregular and quite inadequate to the requirements of all fruit trees. The fibrous roots of well-managed trees are near to the surface of the soil, where they soon become dry, therefore watering must be frequent or the fruits will not develop into fine specimens, nor the trees form pump buds for next year's fruiting. If proper attention has been paid to the watering of the roots during the time the fruits were swelling, no water will be necessary when they are ripening. Cordon and other wall trees that have matured heavy crops of fruits should be liberally fed with liquid manure or some other manual stimulant directly they are cleared of their fruits, and be thoroughly washed with the garden hose. Trees that are making strong shoots will require plenty of water, but no manure must be given them. Specimens that have not fruited well should be marked so that, if necessary, they may be root-pruned later.

Buds and grafts.—The weather of late has not been favourable to budding; success is more certain in damp weather, but where this work has been performed, light syringing and shading will have been necessary in hot weather. Another important operation is attention to grafts; see that no ties are cutting the stocks, and that the grafts are secured to stakes, especially those that are elevated on old stocks and much exposed, as they are most liable to be blown out by strong winds.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LANGRATOCK, The Henley, Moulshamshire.

Early permanent vines.—The laterals of early-forced vines being now well opened, their shortening should be commenced. Remove about one-third of each shoot and all sublaterals from the remaining parts, but in doing this carefully preserve the principal leaves. This pruning will admit an increased amount of light to ripen the wood, and by concentrating the sap will assist the buds that are to produce fruit next season. Keep the borders thoroughly moist, and until the leaves wither liquid manures may be applied with benefit. If insect pests, such as thrip or red spider, are present on the vines wash them with soluble paraffin oil insecticide, repeating the operation at intervals. Apply the specific thoroughly to every part of the vine by the aid of a syringe, working it well into the crevices about the spurs. If mildew has been troublesome spray the foliage with a solution of sulphide of potassium, prepared as advised in a former *Chronicle*.

Muscat of Alexandria.—It is desirable to retain in good condition bunches of Grapes on early-started vines they should be protected from the sun by sheets of brown paper, which will prevent scalding, also dust from resting on the berries. Ventilate the house freely in favourable weather, and maintain a dry atmosphere. Vines upon which the fruit is colouring should be given sufficient fire heat to maintain a night temperature at about 70° with the ventilators slightly opened. A little night ventilation is necessary to prevent condensation of moisture upon the berries. Increase the ventilation early in the morning when the sun is bright, and do not permit a sudden rise of temperature. Atmospheric moisture should be promoted in agreement with external conditions; on sunny days the floors of the house

should be damped early in the afternoon, but this practice must be discontinued in wet weather. Sudden fluctuations in the atmospheric moisture and temperature are liable to cause the berries to crack. Water the borders as is found to be necessary, and in the case of those inside the house attend to this early in the morning of fine days, when the house can be liberally ventilated. Keep the young growths properly stopped and thinned, in order to permit sufficient light to reach the bunches of fruit. At the same time guard against the berries being exposed unduly to direct sunshine.

Late vines.—The continuance of sunny weather is favourable to the colouring of late Grapes, and has permitted the necessary temperatures being maintained without employing much fire heat. The night temperature should be 65° to 70°. The flavour of such varieties as Black Alicante, Lady Downe's Appley Towers, and especially Gros Colmar will be inferior, unless the Grapes are ripened under the influence of a certain amount of fire heat. In order to secure perfect colour in the fruits, the laterals should not be severely thinned, and in very dry weather it may be advisable, especially in houses having large panes of glass, to lightly shade the vines with fish netting. This protection has proved of much benefit in these gardens this season in the case of a house devoted to Lady Downe's seedling; keep the leaves clean and free from insect pests and promote a healthy growth by giving liberal supplies of water at the roots.

THE KITCHEN GARDEN.

By E. BEMBERT, Gardener to the Hon. VICARY GILES, Aldham House, Elstree, Hertfordshire.

Leeks.—The later plantings will require an abundance of moisture, both at the roots and overhead, during the next six weeks or two months. The blanching of the stems should be completed as soon as possible. I have before pointed out the importance of early blanching, for after the shoots are etiolated they may be depended upon to thicken sufficiently.

Celery.—This vegetable has done remarkably well during the past three weeks, and this in spite of the Celery fly being very prevalent when the plants were younger. This pest will probably make its appearance again in the autumn, when its effects are far more serious than in the spring and early summer. As a preventive, fresh soil should be strewn over the plants two or three times a week. Carefully remove all side growths and decayed leaves, and give liberal doses of liquid manure in addition to ordinary waterings. Celery of the best quality can never be produced if the plants are allowed to suffer seriously from want of water. Earthing up or blanching with paper must be done in accordance with requirements. It takes from six to eight weeks at this season to perfect the blanching. No attempt should be made to hasten the blanching of the later batches, as the longer this is deferred the more likely will the plants pass through a severe winter unharmed.

Celeries should receive every encouragement to grow to a large size ready for lifting by the early winter. It is hardly possible to supply this autumn vegetable with too much water, whilst manure in some form should be given liberally. Keep the surface of the soil about the plants frequently stirred with the Dutch hoe.

Onions sown in open ground should now be sufficiently advanced in growth to allow the tops to be bent down. The tops should all be laid one way, and on the side that will most expose the bulbs to the sun. In about a week or ten days these Onions should be ready for lifting and drying off ready for storing during the winter.

Spinach.—Make the principal sowing of this vegetable at the end of the present month or the beginning of next. Though no definite date can be given, owing to the uncertainty of our climate, it is generally safe to sow about the time mentioned; but, in order to make sure of a regular supply of this vegetable during the winter an 1st sowing month, constant small sowings should be made during the next four or five weeks in various parts of the garden. The

surface of the soil should be made very fine, and plenty of soot and wood-ashes should be incorporated with it.

Turnips.—Good breadths of Turnips should be sown wherever land is available; as in the case of Spinach, much depends on the kind of weather experienced during the next six weeks or thereabouts as to the time the roots will be ready for use. I have often had excellent results from sowings made as late as October during mild winters, but very late sowings should be made in a fairly sheltered position. One of the hardiest and best Turnips which I have grown for many years I have found to be Prize-taker, a green-topped variety with flesh of exceptionally fine quality. I have never known severe weather to injure this variety.

Endive and Lettuce.—Continue to transplant these on warm borders and in cold frames as they become ready. Radishes should be sown both in the open and in cold frames.

PLANTS UNDER GLASS.

By THOMAS L. GARDNER to A. STUBBING, Esq., Keir, Perthshire, N. B.

Adiantum Ferns.—All old or damaged fronds should be removed from these plants and the young foliage regulated evenly. A close inspection should be made for scale, and if it is found, remove the whole frond on which the pest is harbouring. Increased ventilation should be given to the plants and less moisture in the atmosphere in order to harden the fronds so that they will better survive the winter for decorative purposes. They will also be less injured by the dry atmosphere of dwelling-rooms if the fronds are hardy.

Stove plants generally should also be afforded less moisture as the season advances. They will not require to be syringed more than once a day, the morning being the best time for the operation. Plants such as *Codiaeums* (*Crotons*) and *Dracenas*, that are liable to attacks of red spider, must be thoroughly wetted, including the under surfaces of the leaves. From this date liquid and artificial manures must be given sparingly.

Caladiums.—The foliage is now getting past its best condition. The amount of water at the roots should be gradually reduced as the foliage begins to fade. Later, the plants should be laid on their side, but still afforded a stove temperature. Although they need to be kept dry, they should not be allowed to become so dry that the fleshy roots shrivel. A suitable place to winter them in is underneath the staging against a wall on the dry gravel of the floor of the house, where there will be sufficient moisture for their proper keeping.

Achimenes.—The earliest batch of these plants will now be passing out of flower, and water should be withheld from their roots. They should be placed on a light, airy shelf, so as to ripen the tubers. When the shoots are dead they should be removed, and the pots or pans placed on their side in a temperature not higher than 55°. Any dry place is suitable for them, and the tubers must be kept perfectly dry all through the winter.

Zonal Pelargoniums.—The pots containing plants for autumn flowering are well filled with roots, and frequent waterings of liquid manure are necessary. By the end of September the plants should be placed in a warm, airy greenhouse with a southern exposure in order that they may receive all the sunlight available during the dull days of winter.

Cypripediums.—The earliest varieties have now set their buds, and should have their shoots tied out evenly, training the tallest shoots in the centre. Use sharp-pointed, green-painted stakes, and in tying-in the shoots endeavour to hide the stakes as much as possible. Never use two stakes where one will suffice. Attend regularly to the feeding of the plants with liquid manure one week, and an approved artificial manure the next. Guard against green fly, and on the first appearance of this pest dust the buds with tobacco powder in the evening and syringe it off in the following morning. Mildew becomes troublesome on some varieties after this date. As soon as the fungus is discovered, dust the foliage with downy mildew underneath as well as on the top of the leaves.

EDITORIAL NOTICE

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Contributions should be written on one side only of the paper and as early in the week as possible and duly signed, not by the sender. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contribution or illustrations, or to claim nearest copyright or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of rare herbs, plants, flowers, trees, &c., but he cannot be responsible for their return.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Appointments for September.

TUESDAY, SEPTEMBER 1.—Roy. Hort. Soc. Coms. meet. Nat. Amateur Gard. Soc. meet.

THURSDAY, SEPTEMBER 3.—Nat. Dublin Soc. Exh. at Royal Hort. Hall, Westminster.

SATURDAY, SEPTEMBER 5.—Soc. Franc. d'Hort. de Londres meet.

WEDNESDAY, SEPTEMBER 9.—Roy. Caledonian Hort. Soc.'s Sth. in the Waverley Market, Edinburgh (2 days).

THURSDAY, SEPTEMBER 10.—London Dublin Union's Sth. at Royal Botanic Society's Gardens.

MONDAY, SEPTEMBER 14.—United Hort. Ben. and Prov. Soc. Com. meet. Nat. Chrys. Soc. Com. meet.

TUESDAY, SEPTEMBER 15.—Roy. Hort. Soc. Coms. meet. British Gard. Assoc. Ex. Council meet.

THURSDAY, SEPTEMBER 17.—Nat. Rose Soc. Autumn Sth. at Roy. Hort. Hall, Westminster.

SATURDAY, SEPTEMBER 19.—German Gard. Soc. meet.

TUESDAY, SEPTEMBER 22.—Roy. Hort. Soc. Coms. meet. Michaelmas, Quarter Day.

WEDNESDAY, SEPTEMBER 23.—Fl. Sth. at the Franco-British Exhibition, Shepherd's Bush (3 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last fifty years at Greenwich, 58° 8'.

ACTUAL TEMPERATURES.—LONDON.—41 Clarendon, August 26 (P.M.): Max. 70°; Min. 55°.

Gardener's Chronicle Office, 41, Wellington Street, Covent Garden, London. *Thursday, August 27 (10 A.M.):* Bar, 29.6; Temp, 68°; Weather—Bright sunshine.

PROVINCE.—*Wexford, August 26 (P.M.):* Max. 45°; Cambridge; Min. 44° Ireland, N.W.

SALES FOR THE ENSUING WEEK.

MONDAY.—Trade Sale, Dutch Bulbs, at 67 and 68, Cheapside, E.C., by Frothery & Morris, at 10.

TUESDAY, WEDNESDAY, THURSDAY, and FRIDAY.—Dutch Bulbs, at 67 and 68, Cheapside, E.C., by Frothery & Morris, at 10.30.

WEDNESDAY.—A consignment of *Prozocra filipini longicornis*, also *Mancasteria*, *Narcissus*, and other bulbs, at 67 and 68, Cheapside, E.C., by Frothery & Morris, at 6.

Nectaries and their Origin.

It has long been known that the honey produced by bees owes its origin, at least normally, to the nectar, or sugary juices excreted by the nectary of so many flowers. But it is not perhaps so generally known that a large number of plants possess glandular structures which also secrete sugar in regions other than the flowers, for example, on leaf stalks, and stipules. It has often been difficult to account for these extra-floral nectaries, as they are called, and all sorts of ridiculous hypotheses have been put forward to explain their occurrence. One view of their function that has been very often advanced is that ants are thereby attracted, and serve to keep off various intruding intruders, for the most part, of a purely imaginary nature.

Amongst plants which possess these extra-floral nectaries we may mention the common bracken fern, which exhibits them at the places where the leaf branches to form the lateral pinnae. Several species of *Vicia*, again, possess them upon the stipules, whilst species of *Prunus* and other Rosaceous plants not infrequently exhibit them upon their leaf-stalks.

A general consideration of the subject tends to excite a suspicion that the supposed relation between plants and ants or other insects in such cases, is probably inadequate to explain the existence of the nectaries. Of course it is true enough that ants are very often attracted by the excretion, just as they are by the sugary substance which is emitted by aphides. But it will hardly be seriously maintained that the aphids get rid of the sugar for the purpose of maintaining a defensive army of ants, any more than that the plant feeds the aphides in order to use them as intermediary paymasters for those protectors.

As a matter of fact there is evidence to show that the structures in question have arisen in a different manner, and that the functions of these extra-floral nectaries have, probably in the great majority, if not in all cases, nothing primarily to do with alluring insects to the plant. Their origin is to be sought in the varying pressure at which water exists in the tissues.

It is a fact, easily verifiable by experiment, that warm conditions encourage the roots to absorb large quantities of water, whilst a low temperature of the soil brings about the reverse result. Thus it may easily happen that while the temperature of the earth is high, and that of the air suddenly falls, water will accumulate to a dangerous extent within the plant, inasmuch as evaporation or transpiration is inadequate for the time being to carry off the surplus. When this happens, a state of things that might easily threaten the health of the plant may readily occur, unless some means of getting rid of the excess of water be provided until the equilibrium between supply and expenditure has again become established.

The excess is commonly eliminated by a more or less complex mechanism whereby drops of water are exuded by the plant. A familiar example of this state of things is afforded by the dew which "falls" on the grass at the close of a summer's day. The earth is thoroughly warm for some distance below the surface, and root action is thereby stimulated, with the result that a considerable quantity of water continues to be absorbed. As long as the warm unsaturated air continues to play over the leaves the surplus water is passed off from them as vapour, but after sunset the cooling of the atmosphere renders it less capable of holding so much vapour, and thus the transpiration or evaporation suits a sudden check. Water continues to be forced into the stem and leaves by the active roots, but the air is no longer able to take off the excess of moisture. Drops of water then become forced out through apertures situated near the tips of the grass leaves, and in this way the dew is formed.

In grasses the organs through which this water is thus eliminated are simple in character, but other plants often develop more

specialised glands which excrete the liquid. With the added complexity of structure the excretion itself may also become less simple. As examples of such organs we may cite the well-known chalk glands that stud the edges of the leaves of many Saxifragas, and at first sight it may not appear to be surprising that sugar, which is so common a substance in plant cells, should also be excreted in the same way. But in reality these excretions are very difficult to explain with scientific exactness, although the fact itself is obvious enough. Probably some direct benefit may accrue to the plant, although it is impossible at present to say what it is. We may, however, assert with some confidence that when we have succeeded in discovering the explanation as to how it is possible for the excretion to take place at all, we shall be in a better position to enquire into its utility from the point of view of the plant.

This exudation of water from leaves is more frequent in the case of these organs while they are young than when they become older. It is possible to see in this a provision for alleviating the strain on tender tissues which would be of little consequence when they reach their full development, but any such "explanation" must be received with caution. The fact itself may, however, easily be verified, and some further interesting adaptations are thereby incidentally brought to light. The leaves of the common Fuchsia, for example, exhibit very well-formed water-glands on the ends of the leaf teeth, and are often spoken of as if they alone were functional in getting rid of surplus water. In the young leaves, however, this is certainly not the case. The surface of the young foliage, like that of many other plants, is beset with hairs, and these are the structures through which alone the water-drops escape while the leaves continue to remain in the downy condition. It may well be that this elimination of excessive moisture forms one of the chief functions of the evanescent down that occurs on the young foliage of so many plants, but this can only be decided by further experiment. This much, however, is certain, that a large number of plants possess organs specifically adapted to get rid of excess of water, and it further seems also certain that the sugar-excreting glands have been derived from these simpler structures, reaching their most perfect form in the widely diverse, but perfectly adapted, nectaries of flowers.

In the case of floral organs no one, of course, questions the existence of the interrelation between nectaries and insects. The whole flower has become, in the higher types at any rate, more and more specialised in its direction, and this, we think, may be accepted in spite of the occurrence of numerous vegetable backsliders that have diverged into lines of reduction and simplification of structure.

We may discern in these floral nectaries abundant evidence of the conversion to a specific purpose of a widely distributed and, at first, somewhat vague and little specialised mechanism. Thus it becomes apparent that a consideration of the origin and history of nectaries may well furnish a fascinating chapter in the story of the evolution of floral structures in general.

ROYAL HORTICULTURAL SOCIETY.—The next exhibition of flowers and fruits will be held in the Society's Hall, Vincent Square, Westminster, on Tuesday, September 1. In the afternoon a lecture on "The History of Garden Making" will be delivered by Mr. THOMAS H MAWSON, A.R.I.B.A.

FLOWERS IN SEASON.—Mr T. SMITH, Daisy Hill Nursery, Newry, sends a shoot of the uncommon *Pyrus (Cormus) foliolosa*, which he describes as a small tree of distinct appearance, resembling a plant of *Gleditschia*. Mr. SMITH also sends a very handsome-fruited Maple in *Acer insigne*. The fruits are of very large size and bright-red colour.

Messrs. JAMES VEITCH & SONS, Chelsea, send sprays of some interesting shrubs and trees from their collection at Coombe Wood. *Acer Negundo marginata elegans* is a fine golden-coloured form, with very large foliage. *Sambucus canadensis* has a bold inflorescence, the flowers being beautifully fragrant. *Eucryphia pinnatifida* is very like *Eucryphia cordifolia* (see fig. 52 in our issue for August 15) in flowering, but the leaves are compound. *Hydrangea Mandschurica* has a moderate-sized inflorescence of rosy-pink flowers; the shoots are almost black, but the green of the foliage is pale and very beautiful. *Buddleia variabilis magnifica* is an improvement on the type, the inflorescence being larger and deeper in colour, and the flowers are disposed in distinct, circular whorls. *Astilbe Davidii*, of which a portion of an inflorescence is sent, is a desirable plant; the long plume-like inflorescence appears shot with heliotrope on a pink ground; the heliotrope shade is present in the anthers and upper parts of the filaments. The box also contained examples of *Polygonum baldschuanicum*, *Hypericum Androsæum*, *Indigofera floribunda*, *Colutea arborescens*, *Fuchsia americana elegans*, *Fuchsia Ricartonii*, *Hypericum kalmanium*, *Hypericum floribundum*, *Buddleia variabilis Veitchiana*, *Cornus alba Spathii*, *Hedysarum multijugum*, *Amorpha canescens*, and *Corylus purpurea*.

Mr. M. CUTHBERTSON, of Rothesay, sends a seedling variety of *Chrysanthemum maximum*. The flower has a small centre, and the ray florets are slightly revolute. Mr. Cuthbertson states that the plant grows about 2½ feet high, and, although the stalks are long and slender, the flowers require no staking.

We have received from Messrs. KELWAY & SON, Langport, Somerset, half-a-dozen inflorescences of *Gladioli*. The varieties include *Winnie Talbot* in a very long spike with 10 expanded blooms and as many in the bud, the flowers being of a deep rose-pink shade and having a white lip; *Golden Ray* has flowers of a pale-yellow or dark cream colour; *Robert Jardine* has flowers of a beautiful cherry-red colour, the lip being of a lemon-yellow shade; the others were labelled *Lady Warwick*, *Muffy*, and *Mrs. Field*, their respective flowers being plum colour, vinous red, and white.

THE LATE SIR DIETRICH BRANDIS' BOTANICAL COLLECTION.—The recently deceased botanist, Sir DIETRICH BRANDIS, who spent 30 years in India, left a valuable botanical collection of Indian plants, which his widow has offered to the Hamburg Botanical Institute. The Senate was advised to purchase the collection, upon which a fixed price of 15,000mk. has been put, the Director of the Institute accompanying his advice with a hint that if the purchase be not soon concluded, the collection, for which two offers from foreign institutes are now pending, will be lost to Germany. The Senate has agreed to conclude the purchase.

BEQUESTS TO GARDENERS.—The late Mr. Wm. JONES, of Quarry Bank, West Derby, Liverpool, left an estate having gross value of £92,006. He bequeathed considerable sums of money to the persons in his employ. To his gardener, CHARLES JONES, he gave £300; to his under-gardener, EDWARD HARPER, and his former under-gardener, MOSES OCKLESHAW, £100 each; and to his late gardener, THOMAS FAIRCLOUGH, £25.

A NEW BOOK.—Messrs. JACK announce the issue of a work to be entitled *Beautiful Flowers and How to Grow Them*, and containing one hundred drawings in colour. The work, which is edited by Messrs. HORACE J. WRIGHT and WALTER P. WRIGHT, will be in 17 parts, and the text will be illustrated with line drawings.

LIMES AS TOWN TREES.—The Lime tree appears to be a favourite one with some landscape gardeners who have to do with town parks, gardens, squares, and avenues, but most species turn rusty in the foliage, and become bare at the very approach of autumn, giving a disagreeable aspect, especially when they are planted in

only ones to be recommended for this purpose, viz. *Tilia vulgaris* syn. *intermedia*, and the Hungarian Silver Lime, *T. argentea* syn. *tomentosa*. If planted in good soil and given proper care, these species preserve their large spray leaves later than all others. As a rule, the Lime cannot be recommended for planting in urban districts.

IRRITANT WOODS.—In connection with our article on "Plants and Skin Irritation," printed on p. 110, the following contribution on "Irritant" wood, which we extract from the *Journal of the Royal Society of Arts*, is interesting: "In the course of the past year inquiry was made by the Factories and Workshop Department into the effect of irritant woods and the extent to which they are used in this country. For example, in the case of satin-wood, there was inquiry into (1) the extent and class of work in which it is used; (2) the evidence there is as to its irritant action on the skin; (3) the precautions taken in its use. Much confusion was found as to the kind of wood referred to as satin-wood—the two covering East and West Indian satin-wood and satin walnut. The first two are practically confined to high-class furni-

[Photograph by C. P. Raffill.]
FIG. 65.—STAPHELIA HANBURYANA; FLOWERS GREENISH-YELLOW, SPOTTED WITH BROWN. (For text see p. 164.)

tures or in avenues. The worst species, writes a correspondent, from these points of view, is *Tilia patyphylos* syn. *grandifolia*. The season of its growth is relatively brief, and even in wet summers the tree is bare of foliage before the month of August comes to an end, and in hot, dry seasons it falls a prey to red spider, which spreads over the under-sides of the leaves and hasten their fall. In London the hot weather in June of the present year had the effect of turning the leaves to a brown colour, and many trees had lost the greater proportion of their foliage in July. At one time the Crimean Lime, *Tilia dasystyla* syn. *euchlora rubra*, was considered by some an ideal street tree. But it is very liable to be affected by a fungus (*Nectria*), and is frequently infested with red spider. A better tree is *T. parvifolia*, which retains its leaves in a green condition till late in the autumn; but its growth is slow, which is against its being employed where quick effects are looked for. There are two species that are better fitted for town planting, both of which grow with vigour, and are not attacked by red spider, and these are the

and furniture making, and to decoration of cabins and overmantel work in ships. Occasionally thermometer stands, backs of toilet brushes, and similar articles are made of it. In these trades it is used as an inlay or veneer involving little exposure to irritant dust. East Indian satin-wood possesses much more irritant properties than the West Indian variety. Satin walnut appears to be no more harmful than deal. The East Indian wood is only used in two shipyards. It causes an eruption on the skin of the worker exposed to the dust or shavings produced during manufacture, but some persons are much more susceptible to its effect than others. One man stated to the inspector that if he only placed a shaving of the wood on the back of his hand it caused a sore on the skin at that point. The injurious effects, however, appear to be only temporary. Exhaust ventilation is in use for carrying off dust, &c., from the machines in most of the works, including one of the shipyards in which the East Indian wood is used. Reference to occasional contact action on the skin is made as to teak by Mr. Inspector WRIGHT (North London), who rejects

to report: 'of swollen arms and eyes,' by Mr. SHANNIN (Liverpool), and by Mr. GRANT (Preston) as to teak and olive wood. The inspector in Sheffield states that: 'In the manufacture of knife scales and tool handles the following woods are considered to be irritant—some of the ebomas, magueta rose-woods, West Indian box-wood, cocos-wood, and partridge-wood. Irritation of the eyes and nose is caused also by woods of the mahogany type. East Indian wood had to be discontinued on the shuttle trade owing to its irritating action on the eyes.' Mr. LEWIS (Manchester) states that sauca-wood from Cuba was stated to give off 'a fluffy dust

WINDOW DRESSING FOR FRUITERS.—This is the title of a publication of 15 pages issued by the Lockwood Press, the publishers of *The Fruit, Flower and Vegetable Trades Journal*. Our fruiterers deal in so much foreign produce coming from all quarters of the globe, including Potatoes, Onions, Lemons, Chestnuts, and Broccoli from the Continent; Oranges from Italy and Jaffa and Valencia, likewise Dates from Egypt, mild-flavoured Onions, and Cob Nuts (Barbanas) from other parts of the Peninsula; Bananas and Tomatoes from the Canary Islands and the West Indies; Apples from Canada, the United States of America, Australia and New Zealand; Bananas, Pineapples, Yams, Persimmons, &c. from the West Indies, there exists endless material for effective window dressing. But the style in which many fruiterers' windows are dressed is not, if read attentively, and its directions followed with care, but modified to suit the locality in which the shop is situated, will help the fruiterer to make his shop as attractive as possible. The booklet is furnished with numerous illustrations, showing better than words how the produce may be arranged for effect combined with convenience for inspection by the buyer.

BANKRUPTCY STATISTICS.—According to a report recently issued by the Inspector-General in Bankruptcy, it appears that during the past financial year there were in England and Wales 7,809 receiving orders, administration orders, and deeds of arrangement; the debtors' liabilities, as estimated by themselves, amounted to £10,888,127, assets to £5,018,122, and the estimated loss to creditors was £5,888,544. These figures show a considerable decrease in the number of failures compared with the preceding year, there being 385 fewer receiving orders and 153 fewer deeds of arrangement. The liabilities exceeded those for 1906 by upwards of £700,000, while the loss to creditors was greater by over £400,000. In Scotland there were 257 sequestrations, with liabilities at £865,232 and assets £226,843; also 146 cessations, in which the liabilities were £38,588 and the assets £7,500. Here also the failures compared favourably with the preceding year in number, although the losses were greater. In Ireland there were 173 bankruptcies and 125 deeds of arrangement, the liabilities being respectively £150,373 and £138,247, and the assets £34,057 and £70,388. In a comparative table attached to the report, we find that the total number of failures, including receiving orders and deeds of arrangement, among gardeners, florists, and nurserymen during the past five years were as follow: In 1903 there were 49 failures, with total liabilities amounting to £33,603; in 1904 there were 49 failures, with liabilities amounting to £29,104; in 1905 the number was 31 failures, with total liabilities amounting to £27,065; in 1906 there were 32 failures, with total liabilities amounting to £62,343; and in 1907 there were 35 failures, with liabilities amounting to £35,467.

Publications Received.—*The Botanical Magazine*, June, 1908, Tokyo, (Agent, Wm. Wesley & Son, 28, Essex Street, Strand).—*Third Annual Report on the Poultry Industry of the Province of Ontario, 1908*. H. K. Cameron, publisher, Toronto).—*The Philippine Agricultural Review* (Bureau of Agriculture Department of the Interior Government of the Philippine Islands), April, 1908.—*The Journal of the British Gardeners' Association*, August, 1908.—U.S. Department of Agriculture Bureau of Plant Industry,

Egyptian Cotton in the South-Western United States, by Thomas H. Kearney and William A. Peterson, Issued June 13, 1908. (Washington: Government Printing Office).—U.S. Department of Agriculture Bureau of Plant Industry, Nomenclature of the Pear; A Catalogue Index of the known Varieties referred to in American publications from 1804 to 1907. Compiled by W. H. Ragon, Expert in Pomological Nomenclature. Issued June 30, 1908. (Washington: Government Printing Office).—New Zealand Department of Agriculture, Division of Biology and Horticulture, Bulletin No. 7. NOTES UPON STAPELIAS.

It is probable that there are no plants having flowers of a considerable size so little known by the general public in the British Isles as the

FIG. 66.—STAPELIA BELLA: FLOWERS DULL PURPLISH-BROWN.

FIG. 67.—STAPELIA BELLA. A, section through the flower; B, C, floral details. (For text see p. 169.)

under the machines and hand planes, the effect of which upon the workers is to cause a running of the eyes and nose, and a general feeling of cold in the head. The symptoms pass off in an hour or so after discontinuance of work.' Eczematous eruptions are said to be produced by so-called Balsam Dis-wood, a wood used owing to its brilliant colour and exquisite grain in fire-saw work, but the Director of the Imperial Institute, SIR WYNDHAM DUNSTAN, who has interested himself in this wood, has failed to discover injurious properties in it.'

FIG. 68.—STAPELIA BAYFIELDII: FLOWERS PURPLE-RED, MARKED WITH PALE YELLOW LINES. (For text see p. 169.)

group of genera collectively termed Stapelias. They are cultivated by few and very rarely exhibited at a flower show, so that most people are unfamiliar with them. This may partly be accounted for by reason that they are considered difficult to cultivate. Nevertheless, they constitute a very remarkable and interesting group of plants, quite unlike any others, and a good many have pleasing or attractive flowers. All are dwarf, succulent plants, varying from 1½ inch to 18 inches in height; their stems are thick and fleshy, with four to many angles and nearly or quite leafless, the leaves being rudimentary or replaced by teeth on slender spines or bristles, in which latter cases the plants have some resemblance to certain species of Cacti (Cereus). As to the flowers, these vary very much in size; there are some that are not more than quarter of an inch in diameter, whilst in one species they attain to over 1 foot in diameter; the majority, however, are between 1 inch and 4 inches in expanse; many are disagreeably scented or have

a carrion-like odour, but some are quite scentless, or their odour is very unobtrusive.

The group comprises about a dozen distinct genera, but those containing the largest number of species and, probably, the best known are *Stapelia*, *Huernia*, *Caralluma* and *Duvalia*. The majority of kinds in cultivation in Europe belong to the genus *Stapelia*, and a number of them are hybrids, for, although they are very difficult to hybridise artificially, yet insects very frequently effect the operation, so that plants raised from seeds produced in Britain and on the Continent are almost invariably of hybrid origin. Many of these hybrids have been unwittingly described by myself and others as species, upon the supposition that the plants had been introduced from South Africa, and it is only during the past few years that I

inch thick, with four rounded, toothed angles, quite smooth and glabrous, dull green, mottled with purple where exposed to the sun. The corolla is about 2½ to 2½ inches in diameter, with very spreading or recurving, ovate, acute lobes, and having a circular raised ring with a flattish, recurved rim on the disc. The lobes are pale greenish-yellow, narrowly edged and evenly marked all over with short transverse lines or linear spots of purple-brown, and the tips of a rather darker shade; they are very minutely ciliate with subclavate hairs. The ring or annulus is much paler than the lobes, being whitish-yellow, with numerous small round purple-brown spots, often more or less confluent.

STAPELIA BELLA† (figs. 66 & 67) is a hybrid, probably derived from *S. glauca* or some hybrid

with a few that are clavate, otherwise they are glabrous on both sides; in the centre of the slightly convex disc is a small cuplike depression containing the corona.

S. BAYFIELDII† (fig. 68).—This is a hybrid raised in Europe, and probably *S. mutabilis* is one of its parents; the stems resemble those of that species, but are puberulous, they are 6 to 8 inches high and ½ to ¾ inch square, with rounded angles having spreading teeth. The corolla has its ovate, acuminate lobes much recurved, but when they are extended the corolla measures 2½ to 2½ inches in diameter; the colour is purple-red, marked to half-way up the lobes with numerous transverse, pale-yellow lines, the tips of the lobes being darker, and they are ciliate from base to apex with rather short, simple, pale-purple hairs; there are a few short scattered hairs just around the corona, but otherwise the inner surface is glabrous. Some hybrid *Stapelia*s raised in Europe have survived under cultivation for many years, but I have not seen this hybrid for a long period, and it would be interesting to know if it still survives.

STAPELIA HIRSUTA VAR. *UNGUIPETALAS* (fig. 69).—Since the publication of this plant as a distinct species, I have learnt that it was raised from seeds produced in this country, and is, therefore, doubtless a hybrid between two varieties of *S. hirsuta*. The stems are 4 to 8 inches high and rather less than half an inch square, with concave sides and minute, erect, rudimentary leaves at the teeth along the angles, dull green, puberulous, velvety to the touch. The corolla is star-like and 4 to 4½ inches in diameter, with long, tapering, lanceolate lobes 1½ inch long and ¾ of an inch broad at the base, incurved or somewhat hooked at the tips, dark purple-brown, marked with transverse yellow lines to two-thirds of the way up the lobes and with five bands of pale greenish-ochre colour on the disc, radiating from the centre of the sinuses; the disc is covered with long, silky, purple-red hairs, and the lobes are fringed with similar hairs of a paler purple. The inner corona-lobes have their inner horns ascending and recurving, but not nearly spreading out to the sinuses of the corolla.

STAPELIA HIRSUTA VAR. *DEPRESSA*‡ (fig. 70).—This variety is a native of South Africa. The stems and flowers are similar to those of var. *unguipectala*, but the corolla is smaller, varying from 2½ to 3½ inches in diameter, its lobes are not incurved at the tips, and there are no pale bands radiating from the centre to the sinuses, otherwise the colouring is similar, but the hairs on the disc are usually rather shorter. The inner horns of the inner corona-lobes are suddenly recurved near their base and spread almost to the sinuses of the corolla. *N. E. Brown, Kew.*

(To be continued.)

FIG. 69.—*STAPELIA HIRSUTA* VAR. *UNGUIPETALA*. FLOWERS DARK PURPLE-BROWN, MARKED WITH YELLOW LINES. A, rostrum and ala; B, ligula (magnified).

have discovered this error. Of the nine figures which illustrate this article, five are hybrids raised from seeds produced in Europe, and the others are genuine natives of South Africa, where natural hybridisation undoubtedly takes place also.

*STAPELIA HAMBURYANA** (fig. 65) is a hybrid between some form of *S. variegata* or hybrid derived from that species, and another of or from *S. mutabilis*, raised in the South of Europe. Its stems are scarcely distinguishable from those of *S. variegata*, being 2 to 3 inches long, half an

form of that species and *S. deflexa*. The stems are 5 to 6 inches high and ½ to ¾ of an inch square, with flattish or slightly concave sides, and small teeth along the angles, dull green, glabrous to the eye, but when examined with a lens and held against the light it is seen to be thinly covered with very minute hairs. The corolla is dull brownish-purple, without markings, and when the ovate, acute lobes are spread out it is about 2 inches in diameter, but, naturally, these are rolled back and are ciliate with long, flattened, tapering, purple hairs, mingled

AMERICAN NOTES.

TWO POPULAR WILD FLOWERS.

Two of the finest wild flowers of North America are the Red Milkweed, *Asclepias tuberosa*, which is frequently used by the florists for decoration, and the Bergamot (*Moradada*), which is variable in colour but usually a mauve or lilac tint. The former grows in the open prairie in stony, sandy and hot positions, but the latter prefers a spot near trees and by the water side, being very fine in many places along the shores of Lake Michigan. These circumstances should indicate the kind of position likely to be suitable for these plants on the herbaceous border. *H. R. R.*

BAYHAM ABBEY.

BAYHAM ABBEY, the seat of the Marquis Camden, is situated about three miles west of Lambethurst and about six miles to the east of Tunbridge Wells on the borders of Kent and Sussex. A stream running through the park divides the two counties. The principal entrance is about a quarter of a mile from Frant Station. Outside the entrance lodge is a row of stately trees of Spanish Chestnut (Castanea), three being on either side of the approach, which leads from the high road to the park. The ground, on entering, rises for some considerable distance, and in the distance above low-lying woods of Fir, Chestnut, Laurel, and Oak can be seen Bayham Abbey. It stands on the south side of a hill, and is sheltered from north winds by a belt of Fir trees mingled with deciduous trees. The Abbey is situated at a distance of two miles from the entrance gates, but the distance appears very much

from the rockery to the Abbey is a mossy bank, on which are growing Oaks and Beeches. The ground in spring-time beneath the trees is covered with bulbous flowers. There are numerous ornamental trees, including many evergreens, but these have not yet attained their full size as the gardens were only laid out some thirty years ago. The mansion itself is not old, being built about the same time; the title was derived from the old Monastery of Bayham, the ruins of which are in the park close to the mansion. This old monastery was founded in 1200 A.D. Many trees have been planted by visitors at Bayham, including a Lime tree planted by his Majesty the King when Prince of Wales, in 1881. Beds of hardy flowering plants are dotted about the pleasure-grounds, and these are gay with their flowers throughout the spring and summer months. There are many hybrid Rhododendrons and many ornamental shrubs and trees, including species of Maple, some with very richly-coloured foliage

the old ruin. Leading out of the pleasure-grounds is a fruit orchard. In one part of this orchard is a plantation of Boskoop Giant Black Currant, and the bushes are in good health. The soil of the kitchen garden is of a stiff, retentive nature, nevertheless good crops of vegetables are procured all through the season. In the plant houses are many Carnations of the Souvenir de la Malmaison type, and these are in an excellent condition of culture. Grapes and Peaches are also cultivated indoors, and other fruits, including strawberries, are forced in their season. In one of the late vinerias are some dwarf Japanese trees, two of Larix leptolepis, one of which is reputed to be 150 and the other 136 years old. The gardens and grounds at Bayham are in the care of Mr. Earp. H. R. Whitlow.

FLOWER SEEDS DIFFICULT TO GERMINATE.

SEEDS of many of the choicer plants, and especially of some hardy perennials, often prove very difficult to germinate. This may result from one of many causes, and only by long experience can a correct treatment be arrived at.

There are a number of plants the seeds of which require to be sown immediately after they are harvested or as soon as they are ripe, when they may, with few exceptions, be expected to grow readily, but should the sowing be deferred for two or three months, or for an even shorter time, they either lose their vitality entirely or require to be in the soil for a period of from six to twelve months before they commence to germinate. An easy way to surmount such a difficulty is to place an order for such seed with some reliable seed house, requesting a supply immediately new seed is ripe, which is usually in the autumn. Seeds that are subject more or less to this failing to germinate include *Genetiana acaulis*, *Asclepias*, many species of *Anemone*, *Primula obconica*, *Phlox decussata*, *Ranunculus*, *Sweet Violet*, *Humea elegans*, *Aralia Sieboldii*, *Trollius*, *Dictamnus*, *Eremurus*, *Clematis*, and *Romneya Coulteri*. Occasionally seedlings will show themselves at intervals extending over a long period, as is the case with *Romneya Coulteri*. The seedlings should be carefully lifted from the seed pan when they are large enough to handle and potted on, but care must be taken to disturb the soil in the seed pan as little as possible. The pot or pan should be kept under observation for at least twelve months before being finally discarded. Happily, many such subjects may be sown in the open ground, and for these a nursery bed should be prepared, selecting a sandy but moist soil. It is useless to attempt to raise such seeds on heavy, cold, wet soils, although in such cases a good layer of sandy loam will improve matters considerably; when this course is impracticable, it will be better to sow the seeds in well-drained pots or pans, filled with sandy loam. Those that are very minute, or expensive to buy, should be placed in a cool greenhouse or frame. If in the latter a thick layer of ashes at the bottom of the frame is essential, for this will help to check the presence of worms, which must be prevented from entering the pots. In sowing, an extra layer of finely-sifted soil should be used, never less than 3-inch, but in the case of large seeds the depth of covering material may be increased to 1-inch. This will permit of a slight skimming of the surface soil should the troublesome liverwort appear, as it often does on pots or seeds that are kept for a considerable time. For perennial seeds in general, equal parts leaf-soil and peat, with one-third its bulk of silver sand, is the best compost. If possible, and in all cases where the seeds are large and known to possess free-germinating qualities, the sowing is best done thinly in the open ground during spring and summer. To sow thinly, the packet containing the seed should be opened at one end and held so as to liberate the forefinger about

FIG. 70.—STAFHELIA HIRSAUTA VAR. DEPRESSA; FLOWERS PURPLE-BROWN WITH YELLOW MARKINGS.

A, flower; B, rostrum; C, beak; D, malformed beak (all magnified).

(For text see p. 169.)

greater, probably from the undulating and timbered lands which intervene. The journey to the residence leads alternately through park and wood, the latter being skirted with Rhododendrons. A row of *Abies Douglasii* is planted on either side of the drive; these trees are about 50 feet in height, and situated at distances of 28 yards apart. The visitor passes through another gateway on entering the pleasure-grounds proper, which has recently been erected to take the place of some former wooden gates. The pleasure-grounds contain a rock-garden which has recently been remodelled. It is planted with a variety of subjects, including many dwarf-growing shrubs and *Wichuraiana* Roses. Nymphæas are planted in a water basin, around the sides of which are species of *Banisia*. Although this rockery is not very extensive, use has been made of every available place for the planting of suitable species. Leading

that are especially fine in autumn. Spring and summer flower bedding is extensively practised. A feature of these flower-beds is a number of pyramidal tiers extending to a height of about 8 feet, which are formed of stout stakes driven into the ground, one tier above another. Over them are trained in summer-time Ivy-leaved *Pelargoniums*; in winter they are clothed with Ivy.

A pergola furnished with a variety of climbing plants leads from the pleasure-grounds to a part of the estate where there are mineral water springs. Inceabout is a summer-house, the water spring in a basin in the centre of the floor. A little distance from this summer-house is a waterfall, the overflow of a great lake; the stream winds its way in a serpentine manner through the park and past the front of the Abbey. There are several beautiful vistas in the grounds near the Abbey, some being near

3 inches above the surface, starting from the left of the pot, the hand holding the pocket should be moved to and fro, allowing the forefinger to cause the contents of the pocket to fall by slight tappings; by this practice the density of the sowing may be easily regulated. In covering the seeds, the finely-sifted soil should be made to pass over the tips of the four fingers, at the same time working the hand containing the soil from left to right in quick succession; by this process an even thickness of soil is made over the whole surface without scattering the seed. In watering freshly-sown pots, great care must be taken not to wash the seeds out of the soil. The spray of water should never be allowed to fall heavily or in straight lines, but the can should be kept constantly on the move from left to right and right to left, using a fine rose. Another good method of watering, especially with very fine seeds such as Begonia and Gloxinia, is to hold the pot or pan in the tank, care to be taken not to allow the water to overflow the surface. Allow it to remain partly submerged until the top soil is moistened by capillarity. Small-seeded aquatic and semi-aquatic plants are easily raised if sown thinly over a patch of growing moss placed on a pan containing shingle and water. *William Mallett.*

BRITISH HEATHS.

DURING August and September one of the pleasantest spots in the garden is the Heath border, which towards the end of summer shows a great variety of form and colour. It is quite possible for anyone who has a light, sandy or loamy soil to grow most of the Heaths to perfection, and one need not go outside our own native species to obtain a very good collection that will do well in almost any position if the simple requirements of the plants are attended to.

The cross-leaved Heath (*Erica tetralix*) is the earliest of our common native sorts, often coming into bloom before the middle of June and lasting until August or even later in a cool summer. It is a capital plant to grow in partially shaded positions or on the edges of pools in water gardens, and among Ferns in the rockery big clumps of it are very pleasing in effect. Unlike most of the other Heaths, this species is not altogether happy in very dry situations, but it will do very well in the open border if it is watered occasionally in long periods of drought. The white form, which the writer has found growing wild in Hampshire and is also seen sometimes in the west of England, is charming as a garden plant.

Everyone is familiar with the common Purple Heath (*E. cinerea*), which grows in such abundance on commons in Surrey, Sussex, and elsewhere. Its dazzling purple, which at times so closely approaches crimson that in the sunlight it is difficult to say which colour describes it more correctly, provides the most wonderful effect in a natural state, and it is even more beautiful than many of our cultivated species or varieties. As a specimen plant in the garden it makes a brave show, and planted in a mass in untidy corners or on poor, bare patches where more fastidious plants will not grow, this Heath is worthy of a place in any collection. The white form of *E. cinerea* is very rare in a natural state, the writer only having found it once and then only as a "sport," but the white-flowered variety can be obtained from Scotland or through a nurseryman. A single plant of a variety of deep crimson colour—so distinct as to be readily distinguishable from its purple neighbours—was found last year in Sussex by the writer.

Less common, but equally beautiful, kinds of native Heaths are the Fringed Heath (*Erica ciliaris*) and the Cornish Heath (*E. vagans*). Both are distinctly local in a natural state, and are not generally known except to diligent students of wild flowers. The Fringed Heath is a downy plant with many branches and small

oval-shaped leaves. Its crimson flowers are egg-shaped, with a small one-sided mouth through which the style is protruded. It flowers all the summer, but is only found wild on sandy heaths in Cornwall and near Wareham and Poole in Dorsetshire. As its name implies, the Cornish Heath is peculiar to that county, and has many characteristic differences from the other members of the family. Instead of drooping, the flowers grow erect in racemes, and the pink corollas instead of being egg-shaped are bell-shaped, with an open mouth. The plant is only found in its natural state in West Cornwall near the Lizard, where it blossoms from July to late August or early September.

Even the common Heath, or Ling, which stands in a class by itself, is not so much appreciated as an ornamental plant as it ought to be.

FIG. 71.—*VERBASCUM LEIANTHUM* IN GLASNEVIN BOTANICAL GARDENS. HEIGHT 14 FEET.

In some places, as on the open commons of Hampshire and Sussex, it is very plentiful, but in other localities it does not thrive nearly so well as the common Purple Heath. In a summer like the present it finds the dry weather very trying, and the bloom is not so good as usual. Its great advantage is that it comes into bloom when the Heaths are beginning to fade and lasts in full beauty till the autumn. When well established it makes a very showy plant in the garden, and forms as good a hedge as Box, if kept clipped, and is much handsomer. It is found wild in a golden form in Scotland, and in many parts of England the white variety is not uncommon. A most striking effect is obtained in the border by planting the ordinary mauve side by side with the golden-foliated and white-blossomed varieties.

Of course, if one likes, it is easy to add to the foregoing by introducing certain of the cultivated Heaths, but those which have been mentioned are all wildings and obtainable in their localities for nothing, or next to nothing. The strictly local varieties can be obtained through any nurseryman in the district. As to culture, although the Heaths will respond to a little generous treatment, they will thrive, once they are established, on the poorest soil, anything which contains sand or peat in liberal quantities sufficing for their needs, provided there is not much lime present. Heavy waterings during dry weather will greatly improve the size and quality of the blooms, especially in the case of *Erica tetralix*. *East Sussex.*

VERBASCUM LEIANTHUM, BENTH.

THE *Verbascum* include many tall and stately plants; some species are showy-flowered and worthy of a place in the herbaceous border. Among the tallest of the genus is *Verbascum leianthum* (see fig. 71), several plants of which are flowering in the Botanic Gardens at Glasnevin. The plants last year formed a large crown of leaves, some of which were 4 feet long by 2 feet wide, and this year they flowered, the largest plant developing a flower-stem 14 feet in height, the branching inflorescence itself measuring 7 feet by 3 feet in width. The plant has a bold and imposing appearance, and is planted in front of a row of evergreen shrubs, which form a fine background, so that the towering spike of yellow blossoms attracts attention from a considerable distance. A grand effect is produced by planting a group of this imposing species. The individual flowers are comparatively small, being only three-quarters of an inch in diameter, but this apparent defect is remedied by the profusion and constancy with which the flowers appear. They are bright yellow in colour, the filaments being covered with whitish hairs, while the anthers are of an orange colour, and before the flower-buds open they are bright and shining. Both stem and leaves are covered with a dense felt of whitish hairs which give the plants a silvery appearance.

The Glasnevin plants were raised from seeds received from Asia Minor, and from Newry. *C. F. Ball, Glasnevin.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

GOOSEBERRY-MILDEW.—In the interests of fruit growers throughout Essex, it is expedient that the greatest possible publicity should be given to the fact that, after extensive ravages in many of the eastern counties, the American Gooseberry-mildew has at length appeared in our county. A Gooseberry-mildew order will be issued by the Board of Agriculture, as a natural corollary, and growers should see that every effort is put forward to ensure the efficient working of the order on their part. The mildew, as its name implies, is a native of America, and was unknown in Great Britain till 1900, when it was found in two Irish counties; by 1907 it had spread to no fewer than 21 counties. In respect to the damage done by the disease, Dr. Pethybridge says, "As regards Ireland, it is no extreme view of the case to state that the losses have been in many cases most serious, and unless the disease is checked, we are threatened with nothing less, practically, than the total loss of the profitable cultivation of the Gooseberry as a bush fruit." What is true of Ireland is true, also, of Essex. I will gladly give any help to Essex fruit growers who care to write to me on the subject. *C. A. Euland, F.R.S., F.L.S., Biologist to the Essex Education Committee, County Laboratories, Chelmsford. August 17, 1908.*

FLOWERS OF SPENSER.—*Aquilegia* is found in Lyte's *Nieve Ho-billy*, 1578, and a quarter of a century earlier Doddeus employs it to distinguish the Columbine. *Aquilegia* is used by Clusius, and *Aquilegia* goes well into the 15th century. *Aquilegia* and *Aguilaria* were applied to a variety of plants. B.

—I do not question that *Aquilegia* is an old name for Columbine; but I can find no good authority for connecting it with *Aquilegus*. As far as I know, all point to *Aquila* and not to *Aquila*. Little is known of authority on derivations. He connects *Aquilegia* entirely with *Aquila* without a suggestion of *Aquilegus*. *Henry N. Ellacombe*.

—On page 29 the author of "The Flowers of Spenser" alludes to Costmary, and says it is almost impossible to say what plant is referred to. Is not *Chrysanthemum balsamita* the plant meant? Asa Gray so describes it, and the fact that Spenser brackets it with *Camomile* increases the possibility. This plant is also known as *Aleost*, because it was used in flavouring beer, and in America, where we adopt a good many old-world names erroneously, it is sometimes called *Lavender*, and *Mint Geranium*. *Emily Taylor Reye, Maryland, New Jersey*.

In Spenser's time *Chrysanthemum balsamita* was knesest as Costmary, but in the passage quoted I think Spenser did not refer to any special plant, but to the ointment, of which one of the ingredients may well have been the *Chrysanthemum*. I might, perhaps, have made this clearer. *Henry N. Ellacombe*.

—Since the recent correspondence on the etymology of the name *Aquilegia* a curious and interesting addition to the evidence has come my way. Quite accidentally I have been informed by an old garden labourer here that the wild Columbine—a rather rare plant in our Wiltshire woods—used to be called *Dropsy-weed*. Now we know that in old times plants were regarded not more from a culinary or medicinal than from the modern aesthetic point of view. The Heartsease, for instance, was so called not because the contemplation of its beauty caused a sense of tranquillity, but because a decoction of the plants was esteemed as a sedative in disease of the heart. We know also that plants were assigned to their several medicinal uses by what was called the doctrine of signatures. They were supposed to have been signed by the Creator with marks to indicate their virtues. Thus the leaves and flowers of the Heartsease were made more like heart-shaped to advertise its efficacy in heart complaints. Similarly Lungwort (pulmonary) and Hepatica were outwardly fashioned so as to attract those who suffer in lungs or liver. It would be quite in accordance with this view of plants that the Columbine, so singularly covered with beads of glittering dew or rain, would be medicinally used to draw off the dropsical humours of the human body, and would be named *Dropsy-weed* or wort, in Latin *Aquilegia*, the water-gatherer. As to Little, it is my experience that even the best leucographers are apt to repeat the derivations of the early botanical writers, just as these repeat one another. Canon Ellacombe, I am sure, will not think me contentious in returning to this very interesting enquiry. In considering such derivations we must take into account two tendencies. First, the older botanical writers were entirely without etymological science. They took the first sound or appearance of a name and explained it accordingly. The first five letters of *Aquilegia* immediately suggested *Aquila*, therefore the name and the flower must have something to do with an eagle. A quite analogous instance is *Pansy*. This is usually explained as a corruption of the French *pansee*. "Pansies, that's for thoughts," says Shakespeare in *Hamlet*. But the old Anglo-Sax name was *Banwort*, the herb that was applied in disease or fracture of the bones, and there is little doubt that it survives in the first three letters of *Pansy*. The other tendency is that of the more scientific modern enquirer to always lever a scientific derivation which have no foundation in fact. Jerusalem Artichoke is never explained as an absurd corruption of the Latin *Girasole*, because it is a Sunflower. As a matter of history, proved conclusively in the *Gardeners' Chronicle*, this plant was grown in England long before it was introduced into Italy, where, indeed, it is scarcely

known even now. And other plants, not Sunflowers, bear the name, e.g., Jerusalem Cowslips, Jerusalem Sage, &c. In this connection Jerusalem means simply foreign or outlandish, and the use probably dates from the time of the Crusades. I can never accept the explanation of Walnut as Welsh or foreign nut, because there is a simpler internal etymology. Its oldest name was *Walnut* in Old English. We know that the Latin *v* fluctuated in time between the sounds *v*, *u*, *w*, and by a quite normal transition *Walnut* would become *Walu-nut* and then *Walnut*, just as a farmer calls oats *wuts*. There is room for a good book on plant-name etymology. When Spenser calls the Poppy "dull" (p. 14), he surely means that opium dulls the senses, and does not refer to the colour of the flower. *G. H. Engleheart*.

—Again I thank Mr. Engleheart for his criticism, but I cannot change my opinion. The Wiltshire labourer's name of *Dropsy Wort* for the Columbine is interesting, but he stands alone, and cannot be taken as an authority. I have many old books on the medical qualities of plants, and none of them give *Columbine* as a cure for dropsy. Lovell, in 1655, gives over 90 plants against dropsy, and *Columbine* is not one of them. The corruption of *Banwort* into *Pansy* will not bear inquiry. All the authorities from much before Shakespeare to the *N. E. D.*, our present great authority, derive *Pansy* from *Pensee*. *Banwort* was a common name for many flowers, including Violets, Daisies, the *Osmondia*, and others, and "*Ban*" might perhaps be changed into "*Pan*," but "*wort*" could never become "*see*." *Henry N. Ellacombe*.

RAT AND SPARROW CLUBS.—Your readers are aware, from the statements that have appeared on the subject, that the organization of the existing rat and sparrow clubs, the creation of similar clubs, and their co-ordination with other existing means for the destruction of rats forms an important part of the policy of my society. My committee propose to effect this organization by means of a National Rat and Sparrow Killing Competition, and to award about £300 in prizes, to individual members for club and county prizes, and for a national trophy. In making the necessary rules and fixing the awards my committee are anxious to avail themselves of the advice of secretaries and members of existing rat and sparrow clubs, and they would, therefore, like to appeal by your courtesy for rules, schedules, forms now used by clubs, and any suggestions that might assist them in producing a scheme for a national competition likely to be of permanent benefit not only to the agricultural interest, but also to the country at large. *J. E. Moore, Secretary, Incorporated Society for the Destruction of Vermin.*

THE DAYLIGHT BILL IN ITS RELATION TO PUBLIC PARKS.—Whatever may be said in general for or against the proposed Daylight Bill, there is not the slightest doubt that in so far as its effect upon the extended use of public parks is concerned it will be of great advantage to the community at large. It becomes law. At the present time, owing to the carelessness of the people, several hours of daylight in the early morning are lost which, by re-arrangement, might be very advantageously used in the enjoyment of recreation in the open air. Recreation of this character always means in addition to the enjoyment derived from it, the possibility of enhanced health to the participants, and when indulged in in public parks and open spaces in some cases a slight gain to the exchequer of the parks department concerned. For these reasons public authorities naturally do all they can to encourage the use of their parks. Let us take the present month (August) as an example of how the Daylight Bill might operate advantageously in the direction indicated. In the majority of parks throughout the country the closing time is very widely regulated according to sunset, and they are usually closed to the public one hour after sunset. Thus, although the evenings at this season of the year are exceedingly pleasant, comparatively few people are able to take advantage of spending them in the parks, as the latter are closed so early that it is hardly possible for working or business people to let to them long before sunset, and the parks are thus of little value to them at this period of the year. For this reason

very few park authorities engage bands to play in their open spaces after the beginning of August, for, although all the climatic conditions are usually as favourable as during the month of July, yet the audiences able to attend during the period of daylight are too small to justify the expenditure entailed in providing musical performances. Evening greens, tennis courts, quiet and croquet grounds, too, are only used for a very short period each day, and the revenue derived from these sources is reduced to a minimum, all on account of the diminution of the time available for indulging in these games during evening daylight, and not because less interest is taken in them at this season. An hour extra daylight would alter all this and enable the people to use the recreation grounds to the fullest extent. As parks and open spaces are now rightly regarded as one of the important factors in the maintenance of public health, everything which tends to their more extended use and permits of the leisure time of the people being spent in them should be encouraged in every way. As the Daylight Bill tends in this direction, it is to be sincerely hoped that its drawbacks in other directions may not be found so great as to prevent its becoming law. P.

DELPHINIUMS.—As mentioned by Mr. Fyfe in his *Calendar* of August 15, these plants deteriorate in quality and effectiveness if allowed to remain in the same position for too long a period. The retaining of old clumps of named varieties is unnecessary, as plants can be raised from seeds quite readily, and there are many superior strains obtainable which bear large flowers of various tints for colouring. Four years ago I obtained a packet of seeds of a hybrid strain. They were sown early in February in boxes and placed in a frame having a slight warmth. When the seedlings were large enough to handle they were pricked off into other boxes and grown on in a cool light position until April, when they were transplanted about a foot apart in nursery beds or borders. They flowered during the late summer and autumn, the spikes attaining to a height of 18 inches to 2 feet, and producing fine individual flowers. I have raised plants from home-saved seed, and have not found any deterioration in the progeny. These young plants are put into their permanent quarters as soon as growth commences actively in the spring. After two years they are best destroyed and their place taken by younger plants. *Delphinium Green of the Blues* I find is best treated as an annual, sowing the seeds in early spring under glass. The seedlings should be transplanted in April about 6 inches apart. This variety has been recommended as a bedding plant, but I find the flowers too fugacious for such a purpose. It is valuable as a border plant, but its flowering time is over by early September. *F. Strat, Ardwell Gardens, Wiltshire.*

CEDRUS DEODARA AND A ROCKERY.—A fine tree of *Cedrus Deodara* that came into my possession when I bought my house 32 years since was a continual source of anxiety to me, for I noticed that the growth was suspended and the tree was almost lifeless. The top of the tree had no leading branches, and its roots flat. I ultimately examined the tree and its surroundings, and I found that ivy growing upon the stones that had been used in building a rockery was most flourishing, and that it was due to the ivy that the growth of the *Cedar* was arrested. The ivy was torn up by the roots, and later on I had the stones that formed the rockery taken away. I am glad to say the tree is now making handsome growth. I remember seeing a similar case in a public garden in London. *T. H.*

GRAPE GROS GUILLAUME.—*Wiltshire Gardens*, p. 148, says this Grape much resembles Black Hamburg in shape and regularity of berry. This is especially so when the individual bunches do not weigh more than from three to four pounds. Such bunches are usually produced in cool herries, which colour and finish well. Some years ago I saw this variety exhibited at a Liverpool show under the name of Pennington Hall Ham borough, and it was awarded the premier prize. In every respect, except flavour, the bunches were identical with superior specimens of Black Hamburg. *E. M.*

REMARKS ON THE FRUIT CROPS.—In my observations on p. 143 the word "Gnomonia" was omitted before the word "disease." It appears to me after several years' observation of this disease that it attacks the leaves so late in the summer that they have fulfilled their functions before they are affected. *Alfred O. Walker.*

THE LARGEST GLASS STRUCTURE USED FOR PLANT CULTIVATION.—According to *Möller's Deutsche Gärtner-Zeitung*, a glasshouse at the branch establishment of the Floral Exchange Nurseries, Edgely, North Wales, Pennsylvania, U.S.A., is 130 metres long, 50m. wide and 11m. high (1m. equals 3.2809 yards). The Carnation house of the Moewes'sche Handelsgärtnerei, at Falkenberg (Silesia), measures 150m. by 9.35m. by 5.5m. The building is figured in No. 16 of *Möller's Deutsche Gärtner-Zeitung*. *Walter Tschube, Rixdorf, Berlin.*

SUMMER PRUNING.—In the gardens of Normanswood, Tilford, Farnham, one of the most beautiful gardens in Surrey, is a grand collection of espalier-trained Apple trees. They are almost perfect in uniformity, the trellis on which they are trained being fully furnished with healthy shoots that are carrying heavy crops of fruit. I did not notice one fruitless tree, but I especially observed how freely the trees were cropped, although not one had then been summer-pruned. I enquired of the gardener, Mr.

sonii, this species has a dwarf, compact habit of growth, the slender shoots being clothed with small pale green leaves that are thin in texture, while in common with most of the others it blooms more or less throughout the summer months. Grown as a loose bush this *Allamanda* is very beautiful, while trained up the rafter of a small or medium-sized structure it is equally at home. The flowers stand out markedly from the others by reason, in the first place, of their widely expanded mouth, but more particularly in their colouring, which is a clear and distinct shade of lemon-yellow—a pretty and uncommon tint. A singular feature in connection with the propagation of this *Allamanda* is that, although cuttings are not at all difficult to root, they can very seldom be induced to grow in a satisfactory manner afterwards. For this reason it is usually grafted on to one of the strong-growing kinds, such as *A. Hendersonii* or *A. Schottii*, and if the point of union is near the ground the scion quickly becomes established, and its cultivation rarely gives any trouble afterwards. *H.*

VEGETABLES AT SHREWSBURY.—I noted with anything but satisfaction that in every collection of dishes which came under my notice—and there were scores of them—that only nine similar kinds of vegetables were represented throughout. That is at once exceedingly monotonous, and at the same time causes neglect of other valuable kinds that can hardly be regarded as of less importance for domestic use. In practically every case, well-known or lesser-known competitors had a back centre of Cauliflowers flanked on one side by Celery, and on the other by Leeks standing erect. In front was a centre of Onions with, on one side, Potatoes, and on the other Carrots, then in front Tomatoes, Peas and Runner Beans. These are all very handsome and imposing vegetables, but some change of effort is needed to shake off the tyranny, as it were, of these select kinds. Because they have for several years past constituted the prime favourites of the leading exhibitors, lesser-known competitors have followed rather slavishly in their footsteps. In the only case in which pointing of the various dishes is made imperative—that of the first-prize collections in the various classes for nine dishes—to enable the winner of the challenge prize to be found, the committee fix the maximum for all kinds at seven points each, thus creating no distinction, real or artificial. Were the maximum graduated, as in the case of fruit, the general absence of Cucumbers, Beet, Marrows, Turnips, and Parsnips might be accounted for, but no such distinction exists, hence all kinds are pointed on the same basis. Possibly exhibitors get to think that inferior dishes of the customary kinds staged are better than samples of kinds not generally staged would be; such an assumption is a mistaken one. No judge, I am sure, finds himself bound hand and foot to any one kind of vegetable over another, and specially so at Shrewsbury, where the society's own point list puts all on the same footing. The question, therefore, I wish to raise is, how, at this, the greatest exhibition of vegetables in the kingdom, it is possible to secure in the competitive classes examples of more kinds in place of a stereotyped few. That seems possible only by the present classes for nine dishes being extended to 12 dishes, or, by the society adding to the challenge prize of 10 guineas to its liberal prizes, amounting to £23, for its own class, making a total of £33 10s., then creating a champion class for 12 dishes or kinds, with four prizes of £12, £10, £7 and £5. That would indeed be a champion competition. Preferably, I would like to see this class made not only a compulsory point class for judging, but also in awarding the cash prizes, as then competitors would get exact cash values as prizes, just as in point judging the values were found. In the society's class for nine dishes with its first prize of £10, and which brought both Messrs. Beckett and Gibson into competition, so remarkably even were the two collections, that when pointed by the first judges they found Mr. Beckett's excelled the other by half a point only. That fact shows how near in point values two collections may be, yet in prize values have been far removed. Mr. Beckett's took £20 10s., Mr. Gibson's but £7, yet the distinction was but half a point. In that case also pointing was done dish by dish, because the

collections were side by side. When some half-dozen or more collections in diverse parts of the tent have to be pointed, the pointing dish by dish is impossible, hence no men, however able, can carry the exact appearance of the respective dishes in collections, pointed some time before, fully in their minds. Knowing something of this difficulty, I should much prefer to see this rival pointing limited to a champion class of not fewer than 12 dishes, in which the respective collections were side by side. *A. Dean.*

NEW INVENTIONS.

GAS HEATING FOR PLANT HOUSES.

DURING a visit to Birmingham in the spring of the present year, on calling to see Mr. K. Fenwick, an amateur who has recently taken up the cultivation of Orchids, and who lives in the Plough and Harrow Road, Edgbaston, our

FIG. 72.—THE "LITTLE NIPPER" GAS BOILER IN POSITION.

Perrin, what his practice was in relation to this form of pruning, and he said that he preferred to allow the wood of breast shoots, which were far from numerous, to become fairly hard before practising summer-pruning. When pruned late in the season, the back buds do not push into growth, but the extra nourishment they receive enables them to undergo partial conversion from wood to fruit-buds. In the gardens at Wood-hatch Lodge, Reigate, where for many years Mr. Salter was gardener, there are many fine bush-trained Apple trees that generally furnish superb crops. Mr. Salter also deferred summer-pruning till the end of July or early in August. This method of pruning made each branch a single cord. It is worthy of note that both at Tilford and at Reigate the soil is of the deep, sandy nature characteristic of Surrey gardens. Although trees on diverse soils need different treatment in relation to summer-pruning, many fruit growers prefer to carry out the method of summer-pruning they have been accustomed to, although some other system might prove better. *A. D.*

ALLAMANDA GRANDIFLORA.—This is one of the most distinct and beautiful of all the *Allamandas*, and at the same time one of the most difficult to obtain from nurseries. Compared with such a well-known kind as *Allamanda Hendersonii*,

FIG. 73.—THE "LITTLE NIPPER" BOILER, SHOWING SECTIONAL ELEVATION.

A, boiler; A1 and 2, circulating tubes; A5, damper or ball; A6, chimney; B, asbestos; C, burner; C1, supply pipes to burner; C4, detachable lid to burner; C5, slots in burner; D, cast iron base; E, hood; E1, c. duct; E2, condensation chamber; E3, condenser pipe.

attention was drawn to a gas-heated apparatus, which is a contrivance of Mr. Fenwick himself, since he found it necessary to provide some kind of heating system for his new Orchid houses.

It has always appeared to us that there are disadvantages connected with the use of gas for the heating of plant houses, the chief one, of course, being that when the stove is placed in the house itself, there is a constant liability that the fumes may escape and inflict irreparable damage upon the plants.

Mr. Fenwick's gas-heated boiler appeared to have several advantages over others that we have seen, and may be useful to many amateurs who do not employ regular gardeners. It is

called "The Little Nipper," and has been patented in Europe and America. It is made in three sizes. No. 1 is said to be capable of heating 200 feet run of 4-inch piping, which has been found to be sufficient for heating a house containing 2,000 cubic feet of space, the cost being about 6d. per day. No. 2 will heat 150 feet of 4-inch piping, being sufficient for a house of 1,500 cubic feet of space. The cost in this case is 4d. per day. No. 3 will heat 100 feet of 4-inch piping, or a house containing 1,000 cubic feet of space, at a cost of 3d. per day.

At the present time Mr. Fenwick is heating an intermediate Orchid house containing 2,000 cubic feet of space with a No. 1 boiler. The consumption of gas per day is 120 feet and the cost is 3d., the gas being 2s. 6d. per thousand. One great advantage in the use of gas, provided it can be employed with safety, is in the fact that it can be perfectly regulated for a long period of time without any further attention. When once the water has been heated the attendant knows quite well how much gas is required to keep that water at a regular heat; and should he leave it for half a dozen hours, there is not the risk that the fire will burn low or that it will give greater heat than necessary. He knows that the pipes will remain in exactly the same degree of warmth as he leaves them, therefore, all he has to concern himself with is the regulation of the ventilators to agree with the changes in the weather out-of-doors.

Mr. Fenwick's case, gas-boilers are used which will only admit of a given number of feet being used per hour, some being suited for 10 feet, others 7 feet and 5 feet per hour, according to the size of boiler. The boiler is made of copper 1-16 inch thick. It has inside cross and upright tubes and is brass, there being no soft solder used in its construction. The whole of the inside space is filled in with asbestos flock, the same as is used in open gas fire grates. The boiler is tested to stand a pressure of 20 lbs. per square inch and a 40 feet head of water. In each case Mr. Fenwick's boilers are placed outside the house. Further details in reference to the construction of the boiler may be sufficiently seen from the illustrations at figs. 72 and 73.

SOCIETIES.

ROYAL HORTICULTURAL

Scientific Committee.

August 18.—*Present:* E. A. Bowles, Esq., M.A., F.L.S. (in the chair); Messrs. C. T. Druery, E. M. Holmes, W. Cuthbertson, G. Gordon, W. Fawcett, H. T. Güssow, J. Douglas, G. S. Saunders, and F. J. Chittenden (secretary).

Aliens in garden soil.—Mr. JOHN FRASER, F.L.S., showed a specimen of the alien weed, *Amaranthus retroflexus*, a North American plant which had appeared in a garden at Kew, though no seeds or plants had been received from there and planted in the garden. He thought that the plant had possibly arisen from a seed introduced with merchandise either from North America or from the Continent, where also the plant has become a weed. He had noticed other instances of plants which had probably been introduced in a similar way, and had become weeds in gardens, viz., *Datura Stramonium*, *Euphorbia Esula*, and *Sisyrinchium angustifolium*, while *Lappula somniferum*, *Eriogonum biennis*, grandiflora, and *Oxalis corniculata rubra*, originally cultivated, had quite frequently become garden casuals, and certain British wild plants, e.g., *Centaurea rubra*, *Erigeron roseus*, *E. hirsutus*, *Lychnis alba*, and *Silene Cucubalis* often behaved in a similar fashion.

Rubus laciniatus.—Mr. FRASER also showed a specimen of a scolding form of *Rubus laciniatus* which he had collected on West End Common, Essex, where the seed had been deposited in all probability by a bird. The origin of this form appeared doubtful, but it seemed to differ only in the lacinated leaves (the sepals and petals also being cut) from *Rubus villosus* var. *Selmeri*.

Rose canker.—Mr. H. T. GÜSSOW showed specimens of a disease of Roses which was very prevalent in Ireland, and which started in the

form of reddish spots on the shoots, which soon died, the dead tissue contracting and cracking. A callus formed around the edges of the wound, and this was frequently damaged by frost, &c., until a large cankerous growth was produced. He attributed the beginning of the injury to the fungus *Coniothrium Fuckelii*, Sacc., the conical form of a *Leptosporia*.

Double Genista tinctoria.—Mr. BOWLES showed specimens of double flowers of *Genista tinctoria* from Canon LILLCOMBE'S garden, and others having numbers of bracts below the inflorescence. This had apparently arisen from the presence of a small dipterous larva belonging to the Cecidomyiidae, which Mr. SAUNDERS reported as that of *Aspidiella genista*. This species is known to attack and form galls on the ends of the shoots of *Genista germanica* in exactly the same manner as in the shoots exhibited. Another species, *A. ulicis*, forms galls resembling flower-buds on *U. europaeus*. There appears to be no record of *G. tinctoria* being galled by a fly, but some of the galls in the present specimens contained no less than fifteen or twenty grubs feeding upon the leaves forming the gall, particularly at their base.

Abnormal Orchid.—From Messrs. HIGGINS & Co. came an Orchid, *Rodriguezia crispata*, showing an abnormal condition in the spikes; the bracts were much longer than the flowers; and very closely grouped at the end of the inflorescence.

Mutations in Shirley Poppies.—Mr. CHITTENDEN showed, on behalf of a correspondent, a number of dried flowers of the Shirley Poppy, all of which had bracts just under the flower or where the flowers should be, some two, others three, four, five, or six bracts without flowers; while others produce bracts with semi-double or quite double flowers. Neither Mr. WILKS nor any member of the Committee had seen bracteate flowers in this plant. It would be interesting to know what was the origin of the seed, and whether the peculiarity came true from seed.

Fern growing in bottle.—Mr. DRURY exhibited in a pickle jar, hermetically sealed, with a glass and rubber stopper, wired on to prevent removal, a mass of vegetation consisting of a *Scolopendrium*, two *Lastarias*, and a dense tangle of coniferoid growth, the whole of which had arisen from a small piece of the base of a Hart's-tongue fern, bearing a minute bud, which had been placed in the jar fully four years ago, and the spores and animal eggs, &c., which had gained entrance with it at the time when it was sealed and secured. About an inch of clean-washed coarse silver sand was first introduced, and upon the damp surface the base and bud in question were simply dropped. The jar is about 8 inches high and 3 inches square, and from the commencement the growth has been healthy, the fronds of the Hart's-tongue Fern reaching the stopper, while the coniferoid growth is dense in the centre, and has spread half-way up the sides. The two seedling *Lastarias* remained small, but have produced new fronds this season, while several healthy green fronds of the Hart's-tongue spring from the centre from amid the debris of the old ones of the three previous years' growths. The question raised by this exhibit is, Whence has the material for all this growth been derived? The originally enclosed air could only have contained a three-thousandth part of carbonic acid gas, i.e., a minute amount of carbon, altogether out of proportion to the debris of dead fronds, and the volume of cellular growth of the living ones which have been generated in the jar since it was closed four years ago. If it be assumed that the glass is porous, and thus permits air circulation, and consequent fresh supplies of carbonic acid gas by the law of gas diffusion, how is it that aqueous vapour has not also been transferred, and the quantity of water reduced during so long a period to nothing? Carbonic acid, too, is not the only food required, and the amount of assimilable salts contained in well-washed quartz sand, freed from all vegetable admixture by such washing, save perhaps coniferous or other spores, can hardly be regarded as adequate for such results, and for persistent growth, such as is shown. A small worm has also been noticed inside the jar. While expressing interest in the experiment, the members of the Committee greatly doubted whether the bottle was really hermetically sealed.

BRITISH GARDENERS' ASSOCIATION.

(LEEDS BRANCH.)

The members of the above association visited Harewood House gardens on Thursday, August 13. A start was made at 1.30 p.m. in glorious weather, Harewood being situated about eight miles distant from Leeds. The flower garden at Harewood is in the Italian style. An herbaceous border extends parallel with the mansion, and this was charming in its colour effects. The pleasure grounds are extensive, and afford some pretty scenery. The kitchen garden and glass structures were inspected. An old Muscat of Alexandria vine, which has fruited for more than 100 years, is dying. In 1903 it carried a crop of 400 bunches of Grapes. J. D.

Obituary.

W. MITCHELL.—Mr. W. Mitchell, for the past fifteen years gardener to J. Willis Fleming, Esq., Chilworth, Hants, died on Saturday, August 22, after a long and painful illness. He was a skilful Grape cultivator, and won many prizes for this fruit at important flower shows, including Shrewsbury, Southampton, and Winchester. With the varieties Mrs. Pince and Madresfield Court he was especially successful. As a fruit judge at flower shows his services were demanded. In private life he was greatly esteemed.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Isles, for the week ending August 22, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather was fair and fine until Wednesday, but subsequently it became very unsettled, with frequent rain and local thunderstorms of considerable severity over the midland and southern districts, and occasional showers in, nearly all the northern and north-western districts. On Thursday the rain was heavy and continuous over a large portion of Southern Ireland.

The temperature was below the normal over the Kingdom generally, but above it in the English Channel, and about equal to it in some other localities. The highest of the maxima were registered on the 10th, 17th, or 21st, and ranged from 77° in Scotland, W., and 76° in the Midland Counties to 71° in Scotland, N. and E. The lowest of the minima, which generally occurred early in the week, varied from 34° in England S.E., 35° in England S.W., and 36° in the Midland Counties and Scotland E. to 44° in Scotland N. and W. and Ireland S., and to 48° in the English Channel. The lowest of the grass readings reported were 25° at Langmarsh Wells, 26° at Birmingham, 31° at Balmoral, and 33° at Hereford.

The mean temperature of the sea was higher than during the corresponding week of last year, except on some parts of the west coast of Scotland, and south-west of Ireland. The annual figures for the English Channel were 61.7° at E.bourne, 61.7° at the Shipwash, and 61.5° at Newquay, to 55.3° at Burnmouth, 54.9° at Aberdeen, and 61.5° at Lerwick.

The rainfall varied a good deal in different localities, but generally it was about the average over most of the English districts and in southern Ireland, below it in most other districts. On the 20th, the total rainfall at the Scotch stations was 1.65 inch at Dublin, and 2.09 inches at Kingstown, and on the 22nd 1.34 inch at Foyens.

The bright sunshine was less than the average except in Ireland and the western districts of England. The percentage of the possible duration ranged from 44 in England S.W. and the English Channel to 20 in Scotland E., and to 15 in England N.

THE WEATHER IN WEST HERTS.

Week ending August 26.

Twelve hours continuous rain.—As in the two preceding weeks the days proved variable in temperature. On the warmest day the highest reading on the thermometer or screen did not rise above 55°. The nights were all more or less warm, the lowest reading indicated by the thermometer on the surface of the lawn being 41°. The ground temperature of about seasonal warmth at 2 feet deep, and 1° cooler than the average at 1 foot deep. Rain has fallen on each of the days of the week, the total being 1.41 inches—equivalent to a watering of 7½ gallons on each square yard of surface in my garden. During the preceding 32 days since a quarter of an inch of rain was recorded. On the 22nd, during a thunder shower, the rain was falling for five minutes at the mean rate of 14 inches an hour, and on the following day rain fell without intermission for 9½ clock in the afternoon, the mean rate of percolation gauge on which short grass is growing still remains perfectly dry, but three-quarters of an inch, or 3½ gallons of rain-water, has passed through the bare soil. The sun shone on an average for five hours a day, which is three-quarters of an hour a day less than the usual duration at this season. Two days previous altogether some 14 miles—direction W.S.W. The average amount of moisture in the air at 9 o'clock in the morning on August 22 exceeded a reasonable quantity for that hour by 8 per cent. E. M. Terkhamul, August 26, 1908.

MARKETS.

COVENT GARDEN, August 26.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must not be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the supply, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Cut Flowers, &c. Average Wholesale Prices.

Table listing various cut flowers and their prices. Columns include item names (e.g., Alstromer, Aster, Callietholica) and prices per dozen or per bunch.

Cut Foliage, &c. Average Wholesale Prices.

Table listing various cut foliage and ferns and their prices. Columns include item names (e.g., Adiantum, Asparagus) and prices per dozen or per bunch.

Plants in Pots, &c. Average Wholesale Prices.

Table listing various potted plants and their prices. Columns include item names (e.g., Anemone, Aralia) and prices per dozen or per plant.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices. Columns include item names (e.g., Apples, Bananas, Grapes) and prices per bushel or per box.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices. Columns include item names (e.g., Artichokes, Beans, Carrots) and prices per dozen or per bushel.

REMARKS.—Runner Beans are exceedingly plentiful and cheap. English Tomatoes are limited to be dearer on account of the dull weather. There are a few good samples of yellow French Tomato, but they have no demand. Plants arriving in large quantities from Middlesex as well as from Kent. Apples are a slightly better trade, although prices continue to remain low. Trade generally slow. Ed., Covent Garden, Wednesday, August 26, 1908.

Potatoes.

Table listing various potato varieties and their prices. Columns include item names (e.g., Kent, Snowdrops) and prices per bushel or per ton.

COVENT GARDEN FLOWER MARKET.

The market presents a very dull appearance. August is the worst month for business and many cultivators of flowering plants are not selling supplies; as a consequence a large part of the stands remain empty.

CUT FLOWERS.

Supplies all round are abundant. Eucharis are plentiful again, but few Gardenias are seen. Stephanotis is abundant and cheap. Tuberoses on the flower stem, better than when the blooms are gathered singly. Good blooms of Chrysanthemums on low stems are plentiful, but the varieties are limited to white and yellow flowers. Prices for these flowers are not so good as they

have been at the same season in former years. Asteri are over abundant, and there are large quantities of Chrysanthemum maximum. Yellow Marigolds are good, also the yellow Coreopsis; the latter is of a pleasing shade of color. Kind the blooms do not last fresh so long as Marguerites. Gypsophylla aurea here there is much appreciated, but its culture is not extensive; it realises about double the price of the single variety. Gladioli French-bleu is remarkably good, but the flowers are thin and weak. Liliums are well supplied, and Roses are over abundant.

POT PLANTS.

Liliums have been over plentiful during the past week, especially the long-stemmed tubicum. Fuchsias are produced in fairly good quantities, also Marguerites; Chrysanthemums are prominent. Dwarf plants which have not been distributed are very useful for planting in borders. The Fuchsias (Syracusa) Queen Alexandra is very good. Ferns, Pains and other foliage plants vary but little; supplies of these are quite equal to all demands. A. H., Covent Garden, Wednesday, August 26, 1908.

GARDENING APPOINTMENTS.

[Correspondents are invited to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

- List of gardening appointments including names of gardeners and the locations they are working at, such as Mr. W. B. Derrinshaw, Mr. C. T. Boorman, etc.

CATALOGUES RECEIVED.

- List of catalogues received from various nurseries and garden centers, including Wm. Drummond & Sons, Ltd., McHattie & Co., etc.

FOREIGN.

WILEY MULLER, Nocera Inferiore, Naples—New and rare plants.

DEBATING SOCIETY.

GARDIFF GARDENERS'.—The 12th annual outing of the Association took place on August 10, when 50 of the members visited Warwick Castle and Gardens. The party was met by the gardener, Mr. Smaie, who conducted the visitors through the gardens and grounds, and afterwards through the castle. Luncheon was partaken at the Grosvenor Hotel. The return journey was made at 7.45 p.m. after a most enjoyable day. R. T. W.

SCHEDULE RECEIVED.

Dumfrieshire and Galloway Horticultural Society's flower show, to be held in the Palmistown Park, Maxwelltown, on Friday and Saturday, August 29, 29, 1908.

ENQUIRY.

SOILS DEFICIENT IN IRON.—Can anyone kindly give me information, from practical experience, as to the benefits, or the contrary, of the application to soils of iron, say in the form of crushed sulphate of iron, where there is a natural deficiency of this element? What would be a safe quantity to use per acre or square yard? *G. H. E.*

ANSWERS TO CORRESPONDENTS.

APPLE SHOOT MALFORMED. *A. H.* The abnormality is caused by the bases of the leaf-stalks becoming swollen and the nodes at the point affected being suppressed. This gives an Apple-like appearance at this spot, so that the shoot appears as though growing through a fruit. The enlarged leaf bases are the result of some irritation, probably set up by mites.

ASTERS DISEASED. *C. H. P.* The cause of the epidemic amongst Asters so universal this season has not been determined, hence no remedy is known. The Fern fronds are browned by a mite; the pest may be destroyed by tobacco water.

BLACK HAMBURG GRAPES AFFECTED. *C. Z.* There is no disease present. The injury is due to scorching, to which Black Hamburg is very subject. Give increased ventilation to the vinery, opening the ventilators early in the day.

BOWLING GREEN. *Bowler.* You appear to be employing too much loam in your green. The best lawns are generally found in Scotland, and we give a description of how a Scotch green is made. Scotch greens measure 126 feet by 126 feet, with a 12-inch deep ditch on the four sides, and, unlike the Lancashire crown greens, are perfectly level. The one great aim in forming these playing lawns is perfection of drainage. The whole area is, therefore, treated in such a manner as to enable water to pass quickly from it. In the ditch 4-inch land tiles are laid, into which 2½-inch pipes—placed in rows at 9 feet apart—discharge any water that may fall on the surface or rise from the subsoil. The further construction as adopted is as follows:—When the site is levelled and drained it is covered to a depth of 4 inches with rough ballast, which is made quite stable by a heavy rolling. A layer of coarse ashes 3 inches in thickness is then placed over the ballast, and, after being consolidated by means of a roller, is, in turn, covered with 3 inches of fine ashes. After this third layer is thoroughly rolled, an inch of fine sand is added, upon which the turves, each 1½ inch thick, are laid and beaten to the desired level. These turves, when cut, are 12 inches square and 2 inches in thickness. Before being laid they are placed, grass downwards, into a wooden mould, 12 inches by 12 inches by 1½ inch deep, and well beaten with a wooden mallet, after which, by the aid of a sythe blade, the superfluous soil is cut away, leaving the turf exactly 1½ inch thick. This process is adopted so as to ensure every turf being solid and of an uniform thickness—attributes they could not possibly possess if cut and laid in the ordinary manner. The turning is done diagonally across the green, and each turf is tested with the spirit level and beaten down to the correct position as the laying proceeds. It will be noted that no soil other than that in the turf itself is used, hence, while the grass cannot grow luxuriantly, it needs careful attention to prevent it from being injured from a want of moisture.—*Morphe.* Mow the green with the box on the machine, and supply the loss the removal of the grass entails to the soil by applying either liquid manure made from ordinary farmyard manure and soot, or artificial stimulants of a nitrogenous nature. Nitrogenous manures will encourage the finer grasses.

COMPENSATION FOR IMPROVEMENTS. *W. C.* Consult a solicitor.

CORRECTION. The parentage of *Cypripedium* Kentia mentioned in the *Orchid Com. tittee's* Report on p. 100 in the last issue is *C. Sandermanianum* × *C. Maudiae*, and not as stated *C. Sanderae* × *C. Maudiae*.

FLORAL DESIGN. *J. B.* A wreath is admissible in a class for floral designs, unless particular designs are mentioned.

GLOXINIAS FAILING. *J. F.* The leaves were too dry when received for a correct examination. Kindly send further specimens packed in damp moss or moist blotting paper.

GRAPES AFFECTED. *F. B.* The fruits exhibit the condition known as "leather berries," due to sudden changes of temperature usually of lower degrees. There is no evidence of injury by sulphurous acid gas.—*Constant Reader.* The trouble is caused by shanking, the result usually of a defective border.—*C. D. and C. B.* There is no disease on your Grapes; the damage has been caused by moisture condensing on the berries. Apply ventilation early in the morning, and be careful not to place too much moisture about the vinery.

GRASS ATTACKED BY A FUNGUS. *G. S. S.* The turf is attacked by Fuligo varians, one of the Myxogastres. The disease is not very injurious, and may be dispersed with a strong spray of water.

GREENHOUSE CONTAINING A SWIMMING BATH. *A. T. H.* Most greenhouse plants would flourish in your house, provided you placed them near to the glass. The roof would form an admirable site for climbing subjects, such as Passiflora, Browallia speciosa, Ivy-leaved Pelargoniums, Jacobaea scandens, Lagageria rosea, Roses of tender sorts, and a host of other trailing plants. We do not advise the culture of Grapes in this structure, as the excessive damp from the bath would probably lead to trouble with mildew and other pests.

KENTIA BELMOREANA DISEASED. *Covent Garden.* The foliage is attacked by a fungus called Colletotrichum Kentiae. Sponge the leaves with White's "Abol" solution at intervals of three days.

LATHRYS OCHRYS. *R. M.* This plant is a native of the Mediterranean region. If you cannot obtain seeds from our hardy plant specialists, apply to one of the Continental nurserymen for them.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruit at a time; they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to consult the following numbers.

PLANTS: *K. M. P. G.* Dendrobium chrysanthum.—*Hilfield.* Eria convallarioides so far as we can judge by the specimen sent, which arrived in bad condition.—*S. F. C. 1.* L. media bicolor; 2, Viburnum marginatum; 3, Abutilon triflorum; 4, Desmodium triflorum; 5, Magnolia species, probably M. conspicua, but send when in flower; 6, Esculus parviflora, commonly known in gardens under the name of Favia macrostachya; 7, probably a species of Quercus, but the specimen is insufficient for determination.—*Tom. 1.* Erythrina Crus-Galli; 2, Clematis (a hybrid from C. coccinea); 3, Berberidopsis corallina; 4, Ceanothus azureus ("Glorie de Versailles"); 5, Abelia chinensis (A. rupestris of gardens); 6, Escallonia exoniensis; and 7, Acalypha margaritana; 2, A. macrostachya; 3, Dracaena terminalis.—*Vitis. 1.* Physalis peruviana; 2, Tanacetum vulgare; 3, Clematis integrifolia; 4, Sedum Alizon; 5, Eupatorium serotinum; 6, Serratula tinctoria.—*W. F. L. 1.* Cypridium insigne; 2, Francoa racemosa; 3, Chlorophytum elatum.—*Houtts.* Veronica speciosa—*Killarney.* 1, Colutea arborescens; 2, Salvia sp. (cannot name without flowers); 3, Lycium chinense; 4, Anaphalis margaritacea; 5, Cedronella triphylla; 6, Philomus frutescens.—*J. B.* Azara macrophylla.—*G. H. H. & Co.* A wretched specimen, but apparently Cichorium Intybus, the common chicory and therefore edible.—*E. F. B.* Spiraea bracteata.—*G. C.* Alnus

glutinosa, common Alder.—*H. E.* 1, Abelia supprettis; 2, Chimonanthus fragrans; 3, Escallonia rubra; 4, Cornus alba (Spatha), golden-leaved variety; 5, Daphne oleoides.—*I. R. J. S. & G. A.* We cannot undertake to name varieties of Roses or Carnations. Send the flowers to some nurseryman who cultivates a collection.—*K. B.* Clethra acuminata.—*H. R. H.* Hibiscus syriacus. Introduced into this country in 1596. It may be propagated by means of layers, cuttings, and seeds.—*J. P. 1.* Aconitum Stoerckianum var. variegatum; 2, Clematis viticella; 3, Clematis integrifolia; 4, Lathyrus sativus; 5, Sibthorpia pergrina; 6, Convolvulus mauritanicus. These were better specimens.

PAPAW TREE FRUITING. *J. S.* The flowers you send are male, but the same tree sometimes produces both male and female blossoms, and in some instances they are hermaphrodite. The presence of fruits on your male plant may be thus accounted for. In a description of this plant in the *Botanical Magazine*, tab. 2,888, vol. lvi., the writer states that "in the stove of the Glasgow garden we long possessed a tree which, from the flowers I examined being male, I imagined was barren. In a few years' time, however, this individual plant produced fruit which came to great perfection, and the seeds of which yielded an abundant stock of young plants." The Algaroba is the fruit of Ceratonia Siliqua, and the name has also been applied to the fruits of Prosopis dulcis and P. siliquastrum. We cannot trace the others you mention.

PARASITE ON IVY AND ROSE. *P. W. G.* The plant infesting the Rose and Ivy shoots is the Dodder, Cuscuta europaea.

PEACH AND FIG TREES UNDER GLASS. *T.* These may be trained so as to completely furnish a glasshouse of moderate size. Some Peach trees we have seen had a spread of branches measuring 30 to 40 feet; we do not know the size of the largest individual tree. The Fig will flourish and fruit for a century or more, and grow to enormous size. Peaches also are long-lived, but in the case of this tree the best success is obtained with comparatively young specimens. The movements of leaves in plants such as you describe are well known, and they are very interesting.

PEACHES DROPPING. *E. M. M.* There is no disease present in the fruits to account for their dropping; the trouble has probably been caused by some check, such as a lack of water at the roots.

PEAR LEAVES INJURED. *H. E. G.* The leaves have been badly injured by the Pear-leaf gall mite. All fallen leaves should be burned, and the surface soil replaced with fresh material during the winter.

PHLEBOSIS LEAF DISEASED. *H. B.* The leaf is infected with one of the numerous species of Anthracnose or Gloeosporium which attack Orchids. Remove the diseased foliage and burn it. Admit as much fresh air as possible to the plants.

PRESERVING FRUITS FOR EDUCATIONAL PURPOSES. *E. S.* The colours of the fruits will certainly be destroyed if you use spirit for their preservation. Try saving them by the sterilisation system, filling the bottles with water, bringing the fluid to the boiling point, and then hermetically sealing the receptacles.

ROSES IN A COMPETITIVE CLASS. *A. R. R.* When the word "dissimilar" is used in the schedule, this is a sufficient indication that not more than one bloom of a variety will be allowed in each exhibit.

SCABIOUS. *J. W.* Varieties of Scabiosa atropurpurea are biennial or annual according to the manner they are treated. It is usual to cultivate them as annuals. Many of them are capable of living until the end of the second season at least. Monthlies are perennial plants.

SEEDS OF ALPINE PLANTS. *F. G.* Apply to any of the hardy plant specialists.

COMMUNICATIONS RECEIVED.—*E. R.* (thanks for 2s. 6d. received for R.G.O. Fund)—*H. H. M.*—*W. J. F. G.*—*A. B. T. C.*—*C. A. J. D.*—*R. E. F. H. P.*—*W. Y. Z.*—*A. H. C.*—*W. F. T.*—*W. L. A.*—*C. S. HARDY FLOWERS AT GLASNEVIN GARDENS.

ONE of the first things that attracted my notice on a visit to these gardens, situated a few miles from Dublin, early in August was a plant of *Gerbera Jamesonii* growing in front of one of the plant houses, and I was interested to find that it is the same plant which gave me my first introduction to this *Gerbera* in the open some years ago. There it has remained and increased in size, producing many of its bright scarlet flowers annually.

Close at hand were many specimens of hardy *Calecolarias*, including the one raised by Messrs. R. Veitch & Sons, Exeter, between *C. plantaginea* and an herbaceous variety of a more tender constitution. Compared with *C. plantaginea* or *C. polyrhiza*, both of which were noticed, its beauty is at once seen to be superior. It is known as Golden Gem. Another *Calecolaria*, hardy in several parts of Ireland, is the shrubby *C. integrifolia*, which forms a tall plant with a hard, woody stem. Strikingly fine, also, was *Convolvulus mauritanicus*, a plant not too hardy everywhere, but growing freely at Glasnevin. The pretty, but rather uncommon *Asphodeline asiaticus* was seen in front of one of the plant houses and in other parts of the garden, its yellow flowers showing to advantage. *Criminus* do well in the open in this Irish

garden, such fine species as *C. Powellii* and its white variety, also *C. Yemensis*, and others making noble clumps and producing many massive flower-spikes.

Glasnevin has long been noted for its *Celmisias*, and, although not in bloom, the collection is of interest, *C. coriacea*, *C. verbascifolia*, *C. Traversii*, *C. Munroii*, and others growing in vigorous health on rockeries and elsewhere. There is also a large collection of *Erodiums*, among these being the pretty, yellow-flowered *E. chrysanthum*, still rare, although introduced into cultivation several years ago. At Glasnevin it is doing well, as also are such species as *E. Kolbianum*, *E. Sibthorpiann*, *E. Wilkomianum*, *E. hybridum*, *E. Manescavii*, and several others.

Campanulas are exceedingly well represented, and among the dwarfier species, of which there is a comprehensive collection, I noticed a very beautiful form of the charming *Campanula pulla*. It was found in Italy, and is known as the Italian form. It is superior to the type in its freer growth, greater neatness, the breadth of the flowers, and other improved characters. It is doing well at Glasnevin, even on level ground. There is a good collection of other species of *Campanula*. Among those I observed were *C. Leutweinii*, *C. primulaefolia*, *C. hay-ludgensis*, *C. turbinata* Isabel, and others of special beauty or of botanical interest. The popular *Dianthus* is to be met with in many forms, such as *D. trifid-culcatus*, *D. alpinus*, *D. zonatus*, *D. neglectus*, and others, the collection being a specially good one, most of the plants apparently thriving well upon the limestone. Among the *Geums*, of which there are many, I was attracted by the effective foliage of *Geum bulgaricum*, although the plant was not in flower. *Potentillas* are excellently represented, amongst them being *B. nepalensis* Miss Willmott's variety, apparently a better form than one I had seen under the same name a short time before. More noteworthy, however, was *P. nitida*. It was flowering with a freedom I have never seen equalled. *Epilobiums* were good and numerous, the newest to me being a pretty pale yellow one labelled *E. luteum*, a dwarf plant, which, if hardy, as it appears to be, will prove an acquisition to the rock-garden or border. The pretty yellow *Cineraria lobata* was also observed, and, as Mr. Moore thinks this may prove hardy, a note should be taken of it by those seeking new plants. Quite a number of *Pentstemon* species are to be found, such as *P. Kellermannii*, the blue *P. heterophyllus*, *P. Hartwegii*, with a very beautiful variety called *pygmaea*, having flowers of a pretty bluish colour and very dwarf in habit. This is apparently an excellent rock-garden plant.

As might be expected, *Saxifragas* are very numerous, there being not only a fine collection of the encrusted or silvery species, but also of those of other types. Among the rarer species I observed *S. crosa* and *S. ranunculiflora*. The species of *Digitalis* attracted my attention, including several already known to me. These plants do not receive the notice they deserve. I observed the pleasing, tall, white-flowered *D. levigata*, also *D. ferruginea*, *D. lutea*, and *D. Lindleyana*, all of which afford material for the

hybridiser. There was also a good collection of *Dipsacus*, and these might be more freely introduced into gardens for their effective appearance. *D. laciniatus*, *L. Leschenaultii*, and *D. Gmelinii* are all good. *Verbanus* also were numerous; one tall and effective plant was called *V. leianthum*. It has yellow flowers, and one specimen was 14 feet high (see fig. on p. 171). *V. phlomidoides* was among the best of the others. *Statice* included *S. Wildenowii*, *S. bellidifolia*, *S. incana*, and *S. Limonium*. The species and varieties of *Sedums* and *Sempervivums* were very numerous.

Of the *Lithospermums* I was specially impressed with the freedom of flowering of *L. intermedium*, which promises to take a leading place among the blue or purple *Gromwells*. The allied *Moltkia petraea* was also fine.

Ramondias and *Haberleas* included the best species and forms of these fine rock plants, and the fine rosettes of leaves showed how well they thrive in the corners in which they are planted in the rock-garden. In passing, reference may be made to a fine specimen of *Rubus australis* growing on a rough pole in the rock-garden and which it is intended should thus clamber into the branches of a tree above. Amongst other rock-garden plants were *Nepeta Mussinii*, *Potentilla speciosa*, *Hypericum fragile* and others, *Silene quadrifida*, *Chrysanthemum argenteum*, *Aster hyssopifolius*, *Coprosma acrocha*, *Thymus lanceolatus* and *T. strictus*, *Euphorbia capitata*, *Arenaria gracilis*, *Senecio laevis*, *Veronica canescens*, and other herbaceous and shrubby species of this numerous family. The pretty *Asperula Gussonei* was growing extremely well. I also noticed *Eurotia pumila*, and two miniature species of *Gunneras* not often seen, viz., *G. magellanica* and *G. dentata*. The handsome *Aciphylia squarrosa*, *Eryngium rigidum* and *E. Serra*, with good *Cytisuses*, *Hedera minima*, and many dwarf shrubs gave a fine appearance to the rock-garden, which, despite some adverse criticisms on the ground of formality, is one of the best I have seen for the welfare of the plants.

Daphne Blagayana, for which Glasnevin is noted, is thriving, and the Glasnevin Lavender is one of the best. The collection of hardy Ferns near the rock-garden is a very fine one, and pteridologists would find ample material to interest them.

The water-garden at Glasnevin is always pleasing in summer-time, and those who do not care to wander down to the water-garden proper will find many fine *Nymphaeas* in little tanks in front of the houses, while the more tender Water Lilies are accommodated under glass. In the water-garden there is a representative collection of the new *Nymphaeas*, such as *gloriosa*, *Wm. Doogue*, *Gladstoniana*; the double tuberosa *Richardsonii*, *Robinsoniana*, *Ellisiana*, and *chromatella*. The water-garden is fringed with moisture-loving plants, and near by is a bog-garden, where many plants are in perfect health, among them being a number of *Primulas*, *P. Poissonii*, in particular, being beautifully in bloom. The shoots are 2½ feet high, although at times in winter the plants are covered with the overflow of the water. Japanese *Fishes* flourish here very satisfactorily.

The herbaceous borders are well planted with choice subjects, and free use has been made of annuals to supplement the display of bloom until the later-flowering plants come into bloom. Among the annuals I noted some plants of a fine strain of annual Larkspur and a beautiful white Iberis.

In the reserve gardens are many good plants, including a collection of seedlings from recently introduced Chinese species. These are interesting, and although many will probably prove to be plants already known in gardens there will no doubt be some novelties amongst them. The collection of hardy plants is worthy of the fine establishment, and the condition of the garden reflects credit on Mr. Moore and his staff. *S. Amott.*

APPLE FELTHAM BEAUTY.

THIS early dessert Apple (see fig. 74) was exhibited by Messrs. James Veitch & Sons at the meeting of the Royal Horticultural Society on August 18th, when the Fruit and Vegetable Committee granted it an Award of Merit.

The parents were stated to be Cox's Orange Pippin and Mr. Gladstone. It is a brightly-coloured fruit of medium size, being flattish-round in shape and highly coloured at the end next to the sun. The ground colour is a yellowish-green, and this has red markings, which sometimes run in streaks towards the eye, which is closed. The stalk is set in a shallow cavity, is about half an inch in length and rather slender. The variety is especially welcome as it is in season at a time when good dessert Apples are scarce. The fruit is very pleasant to the palate, the flesh being brisk and sweet, which qualities no doubt it derives from its first-named parent, Cox's Orange Pippin.

NOTICES OF BOOKS.

"THE BOOK OF THE PANSY, VIOLA AND VIOLET."

IN an introduction to this book the author gives a history of these charming garden flowers. He says: "The origin of the Pansy is to a certain extent wrapped in obscurity" and cites the work of a gardener named Thomson (not Thompson), of Iver, who, it seems, obtained plants of the wild *Viola tricolor* and used this plant as a seed parent to obtain improved forms. This was in 1813. He certainly found they improved, as was natural. But the Pansy was a cultivated plant in England certainly at the end of the sixteenth century. All the early botanists make mention of it as a well-known plant. We a'so know that the play of "Hamlet" was published in 1609, and in the IV. Act Scene V the Pansy is distinguished from the Violet. Poor, distraught Ophelia brings in a collection of flowers and herbs. Amongst them she has "Pansies that's for thoughts." "There's a Daisy; I would give you some Violets, but they withered all when my father died." Spenser, in the *Shepherd's Calendar*, writes of the "pretie pavnice." And Ben Jonson has it, "The panzie this, and that's for lover's thoughts." It is also frequently mentioned in Shakespeare as "Love in idleness."

"Yet marked I where the bolt of Cupid fell;

It fell upon a little western flower—

Before milk-white, now purple with love's wound,

And maidens call it 'love in idleness.'"

* By Howard H. Crane. London: John Lane, The Belley Head.

It was greatly esteemed in those early days, and had many endearing names, such as "Cull me, sweet," &c., but the name of Heartsease is not used by Shakespeare at all, as this name pertained originally to the Wallflower, and, by some misunderstanding, was transferred to the Pansy. Thomson may be left out of the *History of the Pansy*, as he was only one amongst many who cultivated and improved it in the nineteenth century. If Mr. Crane will refer to the first volume of the *Floricultural Cabinet*, p. 192, plate XI., there are three coloured illustrations of Pansies in this periodical showing what had been done up to that time, and during the next seven years there were 21 coloured illustrations of Pansies in this work alone; if we are to believe the artist who painted them, the advance in these seven years was marvellous. There is a yellow self, two yellow-grounds and two white-grounds, as good in form as those of the present day; they are in vol. viii., May 1, 1839. The plates are not numbered.

About that time there were three classes of Pansies, viz., white-grounds, yellow-grounds, and selfs. Of the self colours there were white, yellow and dark, almost black, varieties; but

botanically, they are all specifically distinct. *Viola cornuta* is an old inhabitant of English Gardens. It was figured in the *Botanical Magazine* in 1805, tab. 791. It is a native of Spain and Algiers, and was introduced to the Royal Gardens, Kew, in 1776, by Dr. Ortega. About the middle of the last century or later, when flower bedding was so popular, gardens were ransacked to obtain suitable plants, and in the sixth decade *Viola cornuta* was discovered treated as a weed in some old garden, and was easily propagated, and took its place as lines in "ribbon borders," or edges to beds in the flower garden. It is of free-tufted, wiry growth, and soon smothered most other hardy plants if its growth is not checked. It is seldom seen now. By using the pollen of the Pansy on this *Viola* a much harder plant was obtained than the Pansy, and one that, owing to its slender, wiry stems, stands the heat and drought of the South of England, and thrives where the Pansy will scarcely exist. The introduction is the least satisfactory part of the book; but the author's remarks on the culture and treatment of the Pansy, *Viola* and *Violet* shows that he is familiar with his subject. The various types of

FIG. 74.—APPLE FELTHAM BEAUTY: A NEW APPLE, RIPENING IN AUGUST.

amongst the white and yellow-grounds there was no great variety until about the middle of the last century. The Belgian Pansies were introduced by the late Mr. Wm. Dean, an elder brother of Mr. Alex. Dean. The florists would have none of them at first, and treated them with contempt, just as the Japanese *Chrysanthemum* was belittled by the growers of the incurved varieties ten years later. But the Belgian Pansy came to stay. Others outside the ring of florists took them up, and the result is the fancy Pansy of the present day. They are the result of nearly 60 years' work in Britain. The show and fancy Pansies were doubtless derived by continuous cross-fertilisation from *Viola tricolor*, which is found in its wild state very widely distributed in cultivated ground in Britain.

We now come to what the author of this book terms "Tufted Pansies." He quotes the late Dr. Stuart, who says that "Botanically, Violets, Pansies and Heart's-Ease are all the same." This is incorrect! The Sweet Violet is *Viola odorata*. The Pansy is *V. tricolor*, and the Tufted Pansy has been obtained by crossing *V. cornuta* with the pollen of *V. tricolor*, so that,

Violets and Pansies are described and classified, but surely the author is in error when he states that in the case of exhibition Violets, "Here size of flowers is sought after at the expense of everything else, no matter how coarse the growth, how utterly unsuited for garden embellishment, how difficult to grow, or how far from a really tufted Pansy it may depart, the one redeeming feature of size secures for it a place on the list of specialists, and recognition on the stands at the shows." Surely no person with a judicial mind would place mere size in the first place, ignoring form and good colour. There are chapters on "Propagation," "Planting out in beds," "Exhibiting," "Raising new varieties from seed, and method of crossing." The author has gone into the details of the work minutely, and an amateur, taking up the culture of Violets and Pansies, will be thankful to have so much useful information placed before him. The month of August is the best time to propagate these plants, and in this respect the illustrations of cuttings in the book are valuable, showing the right and the wrong shoots for the purpose. *J. D.*

ORCHID NOTES AND GLEANINGS.

HOLOTHRIX VILLOSA.

FLOWERING in the Orchid nurseries of Messrs. Charlesworth and Co., Heaton, Bradford, is this singular little South African terrestrial Orchid, an inflorescence of which has been sent us. It decidedly belongs to the class termed botanical, but under examination it is highly interesting, and moreover its flowers are delicately fragrant. The leaves are round, fleshy, and hairy, and are borne near to the surface of the soil. The slender, erect inflorescence is about 9 inches in height, and furnished with about 20 small, yellowish-green flowers irregularly arranged on the upper half, the spur of each passing under the proportionately-thick, short pedicel and ovary. It was grown in a cold, freely-ventilated house with *Bartholina pectinata*, which Messrs. Charlesworth showed so well at Holland House, and with which it was impotted.

ARACHNANTHE MOSCHIFERA.

THIS striking species is flowering with Messrs. Sander & Sons, St. Albans, its curious, large, spider-like flowers being produced on stout, fern-like growths. The thick, wax-like sepals and decurved petals are greenish-white barred with chocolate-purple. The short and curiously-formed lip is greenish, the edges of the side lobes and the very short front lobe brown. It has the same general appearance as Messrs. Sanders' recent introduction, *A. annamensis*, although the latter is the showier. Both species require to be grown in a warm, moist house.

CIRRHOPETALUM MACRAEL.

AN inflorescence of this graceful Ceylon species is sent us by Mr. W. P. Bound, gr. to Sir Jeremiah Colman, Bart., Gatton Park, Keigate, who has an important collection of Cirrhopetalums, Bulbophyllums, and other pretty and rare Orchids. The slender scape bears a head of flowers arranged in a very short raceme, and each about two inches in length. The upper sepal is broadly lanceolate, and contorted in a bristle-like point. The long, narrow lateral sepals are pale yellow mottled with rose colour; the small petals reddish, and the fleshy, recurved lip mottled with purple. The species has been known for many years, but is now rarely seen in gardens.

THE ROSARY.

WORK IN THE ROSE GARDEN DURING SEPTEMBER.

THE weather of August was very unfavourable for budding operations, and I am afraid there will be many failures owing to the dry weather. Where the buds have taken they are plump and sound, and if the early-budded Briars are now shortened about half-way, this will help to keep the buds vigorous. Any stocks that have missed are still available for budding if the roots are kept well supplied with water. The work, however, should be completed early in September, for if the weather afterwards sets in wet there will be so great a flow of sap that it will keep the stocks in active growth much later than usual. Budding of the Manetti and the De la Grifferaie stocks should be finished without delay, as there is an abundance of good ripe buds for the purpose. Early-budded Briars starting into growth may be shortened a few inches above the bud to strengthen it. Owing to the dry weather insect pests and mildew abound; the shoots and foliage should, therefore, be well cleansed with suitable remedies in the evenings, and the specific should be washed off again with clean water on the following morning. All soft and weakly-growing shoots should be removed to strengthen those

that remain, and any useless shoots or suckers springing from the stem or roots must be removed also. By a system of early and late propagation and judicious stopping during the growing season it is possible to maintain and extend the flowering period of Roses from May until Christmas without any attempt at forcing. Pot Roses plunged in beds should be brought into a cold house or frame for successional flowering at the end of the present month, but if the weather is mild and open they can be left out till October and be brought under cover in batches as required. The Tea and Hybrid Tea Roses are now more brilliant in colour than at any other season of the year, and they will continue to flower well for a long time to come, especially if after the end of September a temporary framework is made for their protection. A suitable structure may be made with garden lights, leaving the sides and the ends of the structure open. This applies only to dwarf pot plants plunged outside in beds. The following are specially bright and varied in colour just now: Belle Siebert, Mme. Testout, Triomphe de Perné Père, Liberty, Grand Duke Ernest Ludwig, Falcot, and Safrano. Some years ago I saw growing at Messrs. Lévêque's nursery near Paris, during September, many thousands of pot Roses plunged outside, and it was an object lesson to see the wealth of varied colours on the plants. Many of them were not more than six or eight months old from the graft or cutting.

Keep the hoe well plied amongst borders and beds of Roses. This will assist in aerating the soil and also promote the ascent of moisture from the water level. Those beds and borders which have received a good mulching and abundant watering during the summer will now show to great advantage. The flowers, foliage, and growths of the plants will be fresh and abundant.

At the end of this month the pot Roses that were forced and stood outside during the summer can be potted or top-dressed according to the state of the roots. If top-dressed, 2 inches of the old soil should be taken off and replaced with good turfy loam, a little rotten manure, and bone-dust. See also that the drainage in the pots is perfect. When Roses have been in the same pots for more than two seasons they usually require a shift into receptacles a size larger. Sometimes they will be found to have made few or no roots; in this case they should be returned to the same pots, after the pots have been washed. Pot firmly, using two-thirds good loam, the remaining third being burnt earth, sharp sand, and manure. The re-potting of the bulk of these Roses can remain over until next month, when a general overhaul of all the plants in pots will be necessary. Roses planted out under glass should be lightly pruned at the end of this month. They should be allowed an abundance of ventilation both night and day, and be kept well syringed while bright weather lasts. The material for potting purposes next month should be prepared at once. Fresh loam or turf should be mixed with road grit, burnt earth, rotten manure, and soot, and well exposed to the weather at least a month before it is required for use. The best plan is to have the loam, turf, and manure stocked in alternate layers some six or eight months before it is required. Soil near towns soon loses its fertilising properties and requires frequent renewal. Now is the best time to do this in readiness for planting next month. The old soil should be cleared out and fresh maiden loam, turf, and well-fermented manure be substituted. Climbers and bush Roses thrive best near towns; standard Roses are usually short-lived. Hybrids of Bourbon and China Roses are very suitable for town planting. A selection includes Blaini No. 2, Coupe d'Hebe, Chas. Lawson, Paul Ricaut, the old Provence, old Pink and Crested Moss, and old Cabbage Rose. The following climbing varieties are also suitable: Bennett's Seedling, Dundee Rambler,

Félicité-Perpétue, Laure Davoust, Sweet Briar, and Mine. d'Arblay. Only a few kinds of the Hybrid Perpetual class are likely to do well in smoky districts, the best being Boule de Neige, Mrs. John Laing, John Hopper, Anna Alexiff, Duke of Edinburgh, and Ulrich Bruaner. J. D. G.

TREES AND SHRUBS.

OXYDENDRON ARBOREUM.

WITH the exception of many species of Heaths and their numerous varieties, there are few Ericaceous plants that bloom during the latter part of the summer. Included in the list is *Oxydendron arborescens*, which forms an ornamental flowering shrub. It is an old plant in gardens, having been introduced from North America in 1792, where in a state of nature it is said to occur from Pennsylvania to Florida, in the valleys of the Alleghany Mountains. In its natural habitat the plant attains the dimensions of a tree, but in this country it must be looked upon more as a shrub, and it blooms freely when less than 6 feet in height. While the generic name of *Oxydendron* is now regarded as the correct one, the plant was formerly known as *Andromeda*, also *Lyonia*, the specific title in each case being the same. Popularly it is the Sorrel Tree or Sourwood of the States. The leaves are oblong-lanceolate in shape, glabrous, and of a dark green hue. In the autumn the foliage changes to a brilliant shining-red colour, and frequently remains in this state for some time before delimitation. The flowers are borne in long slender, partially drooping racemes on the branches of the preceding year; they are white, urn-shaped, and of thick wax-like texture. This species of *Oxydendron* needs a fairly cool, moist soil of a peaty nature.

HIBISCUS SYRIACUS.

APART from the beauty of its blossoms, this *Hibiscus* is very interesting as being almost the only shrubby member of the large order Malvaceae that can be regarded as hardy in this country. It is, however, only hardy in the southern parts of these islands. A warm, well-drained soil is best suited to its requirements, and a hot, dry summer is particularly conducive to the formation of flower-buds. In all its varieties this *Hibiscus* forms a sturdy-growing deciduous shrub, seldom more than 6 feet to 7 feet in height, and is of a somewhat erect habit. While the bark of the young shoots is greenish, the old wood is usually of a decided greyish hue, which in winter when devoid of foliage forms a notable feature.

Of the many named varieties in cultivation there are more kinds with double or semi-double blossoms than with single ones, but I prefer them with single flowers. A delightful variety is *Corleste*, whose large, well-expanded blossoms are coloured bright blue, with a reddish tinge towards the base of the petals. It has of late become very popular. Other good single varieties are *Totus albus*, with pure white flowers; *Rubus*, the best of the reds; and what I regard as the typical *Hibiscus syriacus*, a white flower with a large crimson blotch at the base of each petal. Of double kinds may be especially mentioned *albus plenus*, double white; *anemone-florus*, dark red; *Boule de Feu*, bright red; *caruleus plenus*, bluish; *famosus*, rose-white; *Lady Stanley*, rose; *speciosus flore pleno*, pale pink.

This *Hibiscus* is said to have been introduced to this country as long ago as 1596; London mentions seven varieties. The question of its native country has aroused a certain amount of controversy. The specific name would suggest that it is a native of Syria, and the *Kew Hand List* gives as its native country the Orient, but I believe it is now regarded as indigenous to China, having been found wild in different localities in that country. W.

NOTES FROM A "FRENCH" GARDEN.

We are sowing in frames in well-prepared soil seeds of a dwarf strain of Ox-Heart Cabbage. Germination is hastened by light but frequent waterings. Should the weather prove very wet, the lights will be placed on the frames, although an abundance of ventilation will be given. Another bed similar to the one for the Ox-Heart Cabbages has been prepared for the sowing of Cauliflowers Driancourt, Lambin, and Lenormand. The heads will be ready for cutting in the coming spring. Beds have also been made ready for pricking off Lettuces in October; as it is important to take advantage of the fine weather, all the hot-beds at liberty are being turned over; the old manure is well broken up, and will be used to form a layer 2 inches in thickness on the beds for the Lettuces. Seedlings of Onion Little Paris Market are coming through the ground; they will be pricked off at the end of September.

The Lettuces sown at the beginning of August have been transplanted under cloches, 30 to each cloche. The plants are doing well, the present dull and windy weather being favourable to their growth. We have set the cloches on the beds, where the Lettuces will be planted out in groups of four; the glasses are covered with mats to keep the soil in good condition.

All the Winter Spinach has been sown. The Endives La Ruffec and the Batavian Green are well established in their winter quarters.

The crop of Endive La Rouennaise planted at the end of June on the old manure beds is now marketed. They must be dispatched in a very short time after the heart is bleached, or the outside leaves soon decay.

All the Cauliflowers are growing freely: the plants need constant attention and frequent waterings in order to keep the leaves tender and green, and to guard against aphides and caterpillars, which are numerous at this time of the year.

In the old-established "French" garden a sowing of the first batch of Cabbage Lettuce Little Black Gott has been made under cloches. The seedlings will be pricked off a week later, 30 to each cloche, in a well-situated part of the garden. They will be planted on hot-beds during the middle of November. This is not very profitable, but it is done to find work for the staff during November and December, and to advance the making of the hot-beds in January. This crop is cleared for the New Year; the beds are then turned over and mixed with a quantity of fresh manure to be used for another crop. *P. Aquatics, Mayland, Essex, August 27, 1908.*

ANTHURIUMS.

SPECIES of Anthurium which are cultivated for the beauty of their leaves require a considerable amount of room for their development, much more than those that are grown only for their flowers. Each section requires different treatment, and while they readily respond to generous culture, there are certain conditions essential for their successful growth.

The flowering species are propagated in the spring by removing the side shoots with roots attached. Pinch out any flowers that may be present on the offset, and insert the shoot in a mixture of fibrous loam, broken crocks, charcoal and silver sand. Anthuriums ramify best in soil which is in a lumpy condition, perfectly sweet, and through which water will pass readily. From start to finish they require an abundance of water. Plunge the pots containing the shoots in a bottom heat of 65° F., and in a few weeks they will have made roots in sufficient quantity to warrant their being taken out of the propagating case and shifted into larger pots, but over-potting must be guarded against. Use a similar compost as before, with the addition of some lumps of flaked cow manure broken to the size of Walnuts, and

return the plants to the propagating case for a few days. Shade them from bright sunshine and admit a little ventilation to the frame during the middle of the day. Keep the plants damp by syringing them two or three times daily. On taking them out of the case, place them on the shady side of the pit, gradually inuring them to more light as the summer advances, but never expose them to the full force of the sun's rays. Apply plenty of water both at the roots and overhead. The temperature may be allowed to drop in the autumn, and less water will be necessary through the dull months of the year. A night temperature of 55° will suit them admirably. Insects may be kept at bay by immersing the plants in the XL-All or some other insecticide. Repot the plants in April in soil similar to that already advised, using lumps greater in size at each successive potting. In the summer a few flowers will appear, but the object of the cultivator should be to encourage growth rather than the production of flowers. Treat the plants through

sow them in spring time on a mixture of chopped Sphagnum-moss, finely broken charcoal and crocks with the addition of a little sand. The drainage of the seed-pans should be as perfect as possible. Do not cover the seeds, but let them lie evenly upon the surface. Cover them with a bell-glass or place the pans in a propagating case having a night temperature of 65°; they will germinate in about six weeks. Allow the young plants plenty of light, but do not permit the sun's rays to burn them. Syringe the seedlings overhead each afternoon and give them fresh air at midday, increasing the amount according to the growth and vigour of the plants. In September prick the seedlings into 3-inch pots and keep them through the winter in a temperature of 60° to 65° at night, increasing it 10° by day. They must be potted as required, and should always be allowed an abundance of rain water. From this point they may be treated as advised for the rooted shoots. Slight variations in the colour of the spathes of the various species may be found, and this adds

[Photograph by J. Chenhallis.]

FIG. 75.—ANTHURIUM WAROCQUEANUM: IN THE COLLECTION OF A. LANYON, ESQ., TOLVEAN, CORNWALL.

the following winter as in the one before, and repot, if necessary, in April. After this stage flowers will appear profusely. When the brightness of the flowers has waned in early August, an excellent opportunity will be afforded to overhaul and clean the plants, potting them or giving them a good top-dressing as may be required. Flowering seems to exhaust the plants, but top-dressings or waterings of liquid cow manure serve to increase their vigour again before winter sets in. Anthuriums may also be increased by cutting the stems into pieces 2 inches long and placing the portions in a very sandy soil in heat, as is done with various species of *Draena*. This method of propagation takes a longer time than that described above, though one stock plant gives a large number of new plants by this means of increase.

A. Scherzerianum and its varieties, also A. Andraeanum and its varieties, may be grown from seed. Wash the seeds from the pulp and

to the interest of raising the plants from seeds. The soil must never be allowed to become sour, and if this should occur, it is best to cut off all flowers, wash the roots in warm water, cut away any dead roots and decayed parts, and pot them in fresh, sweet soil, afterwards plunging them in bottom heat to assist fresh root action.

SPECIES WITH ORNAMENTAL FOLIAGE.

Some of these possess large, handsome, velvety, and diversely-shaped leaves, which renders them exceedingly attractive. They are propagated by suckers during the spring or summer months; also by taking off a portion of the main trunk when the annual potting takes place. A piece of the stem 6 inches long should be cut into three portions, and these placed singly in 4-inch pots, in a mixture of Sphagnum-moss, charcoal and broken crocks and plunged in a bed having a temperature of 65° to 70°. One

or more shoots soon make their appearance; these should be potted on and given a liberally rich soil, consisting of lumps of rich fibrous loam, some fibrous peat, cow manure, charcoal and broken crocks. Keep the plants well watered and shaded, pinch out all flowers as they appear, and maintain the plants scrupulously clean by frequent syringings.

The temperature should be higher (80° to 85°) than for the flowering varieties, but they need an abundance of water both at the roots and overhead. A moist atmosphere, such as is found in a Cucumber house, is an ideal one for these Anthuriums.

A. Waroquenatum (see fig. 75) is one of the handsomest species. It grows to a height of 4 feet 6 inches, and the leaves measure 45 inches in length and 16 inches in breadth. In colour they are a handsome green crossed with silvery white veins.

A. splendinum is well described by Mr. Bull as follows:—The course of the nerves is marked by a broadish band of deep lustrous vel-

roots have formed in this upper soil, it is possible to cut off the part in the pot, and to sink the upper part now cased in the netting into a fresh pot without damaging the plant. By this means the plant may be kept quite dwarf.

The illustrations (figs. 75 and 76) are of plants in the collection at Tolvean, Redruth, Cornwall, the seat of Alfred Lanyon, Esq. The structure in which they are housed is heated by four rows of pipes running under the side benches. Under the central stage there is a tank the length of the house, which feeds a dip in one corner. The house is a span-roofed structure with a lantern. The principal plants grown in this stove are:—Anthurium, Allamanda, Calathea (Maranta), Stephanotis, Ikora, Euphorbia, Eucharis, Codiazem (Croton), Acalypha, Hibiscus, Cycas, Hemanthus, and Dracena. The gardens were under the care of Mr. John H. Bowden, during which period they were noted for nearly 40 years for their stove and greenhouse specimen plants. Mr. Bowden has recently retired. H. W., Tolvean, Redruth.

tion of these Orchids, for upon its proper carrying out largely depends success in their culture. The early autumn is generally regarded as the best season for the affording of new rooting material to these plants, the cool nights and moist atmospheric conditions then prevailing affording conditions favourable for the re-establishing of the plants before winter sets in. No delay should, therefore, occur in proceeding with these operations. As regards the manner of potting and material employed, these have been previously noted, and it is only necessary to add that pots or pans which are too large in size should not be used. We employ a compost similar to that recently advised for Miltonias. Everything used in the repotting should be thoroughly clean and sweet, and provision should be made for thorough drainage. Specimens that have been left undisturbed for a few years, and that are now showing signs of exhaustion, should be given attention. Shake away the old potting material from the roots, and remove any old and useless pseudo-bulbs. Use pots just large enough to accommodate the roots for one season only. Vigorously-growing plants that need much root space may be shifted, without disturbance of the ball, into receptacles large enough for the proper development of two seasons' growth. Plants that need resurfacing only should be attended to and then be placed by themselves, otherwise it will be difficult to distinguish these from the newly-potted ones that will require a different treatment in watering. The usual precautions must be taken with newly-potted plants. Exercise special care in watering those that have had the old material entirely removed. Regulate proper atmospheric conditions by judicious damping of the bare surfaces about the plants and the admittance of proper ventilation. Careful shading will be needed on bright days, and the plants may be sprayed overhead two or three times daily when the weather permits.

Propagation.—Odontoglossums may be increased by means of the pseudo-bulbs. Select the stems, label them, and place them together on a bed of Sphagnum-moss in a box close up to the roof glass in a cool house. Another method of increase is to sever the rhizomes between the pseudo-bulbs whilst growing in the pots. If these divided portions are leafy stems, they form roots readily.

THE FLOWER GARDEN.

By W. SYRZ, Gardener to Lady WINTON, Lockings Park, Berkshire.

Bulbs.—Preparations should now be made for the planting of bulbs. Heavy soils will be benefited by the addition of leaf-soil and sand, and the ground should be dug to a fairly good depth, leaving a fine tilth on the surface. There are many places where bulbs are planted, such as land skirting woods and shrubberies, also banks and grass lands, where it is not practicable to dig the soil, but numerous holes may be made the width and depth of a spade and be filled with some richer soil, such as discarded potting loam. The bulbs will grow well in these prepared places, but if this system cannot be practised holes may be made with crowsbars of different sizes to be filled in with a little fresh soil, taking care not to plant the bulbs too deeply. As bulbous plants thus utilised are not shifted each year, a little extra trouble in their planting will be well repaid. There is a great variety of subjects suitable for planting in these natural spots, including Daffodils, Chionodoxa, Colchicum, Crocuses, Eranthis hyemalis, Snowdrops, Tulips, Hyacinths, Jonquils, English and Spanish Iris, Leucocimus, Muscari botryoides, Fritillarias, and Anemones.

Seed collecting.—Collect seeds of all hardy plants that are required, as soon as they are ripe, and it must be remembered that even if the same plants the seeds seldom ripen at the same time. Seeds collected before they are ripe are not satisfactory; it is much better to gather them at intervals of two or three days, choosing fine weather for the work. The seeds should be cleaned, properly labelled, and stored in a cool, dry place. Many kinds of early spring-flowering plants may now be sown, such as *Collinsia bicolor*, *Saponaria calabrica*, red and white-flowered *Candytuft*, *Clarkia marginata* and *pulchella*, and *Virginia Stock*.

(Photograph by J. Chenhalls.

FIG. 76.—ANTHURIUM VEITCHII: IN THE COLLECTION OF A. LANYON, ESQ., TOLVEAN, CORNWALL

very green, the intervening spaces of about equal width being in striking contrast, of a pale yellowish green. . . . This is a very beautiful species.

A. Veitchii (see fig. 76) has leaves 40 inches long and 12 inches wide, with a glossy metallic surface. The principal nerves are arched and deeply sunken, presenting a curiously waved appearance. A full-grown plant will measure as much as 6 feet across.

A. crystallinum is an old and well-known variety, with rich velvety green leaves having white crystalline veining. The leaves are ovate and present a handsome appearance.

Towards the end of the summer large plants may become leggy and the leaves become reduced in size; for some years I have adopted a plan to augment the amount of rooting material by placing a piece of half-inch mesh wire netting around the stem of a diameter to fit inside of the rim of the pot. This is lined with living Sphagnum-moss and filled with large lumps of loam, peat and cow manure. Eventually, when

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALFANDER, Orchid Grower to Lt.-Col. G. L. HOLFORD, C.V.O., C.I.E., Westbury, Gloucestershire.

Odontoglossums.—The spring and early-summer flowering members of this genus are the most popular of all the cool-growing Orchids. The species *O. crispum*, *O. Pescatorei*, *O. Hallii*, *O. Harryanum*, *O. triumphans*, *O. luteo-purpureum*, *O. cirrhosum*, and their hybrids, with their very numerous and beautiful varieties, are all extensively cultivated. Their cultural requirements are very similar, and they can be successfully grown together in a cool, well-cultivated structure. If the situation of the structure in which *Odontoglossums* are accommodated is an exposed one, periods of hot, dry weather, such as have been experienced this summer, are detrimental to their well-being, owing to it being a difficult matter to maintain a suitably cool and moist atmosphere.

Potting and re-surfacing Odontoglossums.—Repotting is an important detail in the cultiva-

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq.,
Kear, Fonthill, N.E.

Bougardia.—Plants growing in unheated frames or in borders out-of-doors will need to be potted at the end of September, and in order that they may not experience a severe check when they are shifted, it will be better to cut the soil around their roots some distance from the stem with a sharp spade. After having cut around the plants in this manner, afford them a good soaking of water to avoid giving them a check. As soon as potting is completed they should be kept in a close atmosphere for a few days and be shaded from bright sunshine. Worms are sometimes present in the soil attached to a plant's roots, and these creatures afterwards become troublesome in choking the drainage. They may be destroyed with lime water. *Salvias*, *Calias*, and *Fatoumums* that have been planted out should be treated in the same manner as *Bouvardias*.

Hippocratum.—These plants are now finishing their season's growth, therefore they will require less moisture at their roots; directly the leaves begin to die, water should be withheld altogether. At that stage the plants should be placed in a cool, dry atmosphere, but it will be necessary to prevent the bulbs becoming shrivelled from excessive dryness. For this reason it will be advisable to examine them at intervals. Plants having leaves still very green should be placed in a sunny position in order to hasten their ripening, for unless this is perfected their flowering will not be satisfactory.

Agathaea calcestris.—Do not pinch off any more of the flowering shoots than those plants intended for winter flowering, but it may still be practised in the case of plants which are required to provide a succession of flowers in spring.

Primula.—*Primulas* should be afforded a sunny position and be allowed plenty of room. The flower-spikes of the earliest batch of plants may now be allowed to develop, and these plants should receive occasional applications of liquid manure.

Preparations for winter.—Plant houses should now be thoroughly cleansed; all the glass and woodwork should be well painted, and the plants afterwards arranged in position. The present is a suitable time to repair or to paint glass structures, for temporary room can now be provided for the inmates in other houses. After a house has been freshly painted the ventilators should be thrown wide open for several days, and when the paint is dry the woodwork should be syringed two or three times before the plants are again placed in the structure. If plant pots are placed on newly-painted woodwork without first wetting the wood, the pot will stick to the paint.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to THE DOWAGER LADY
NUNBURGHOLME, Water Priority, Yorkshire.

Peach trees.—The fruits of *Amuden June*, *Alexandra*, and other early varieties of Peaches on south walls will now have been gathered. The trees should, therefore, be syringed with some suitable insecticide to cleanse them from red spider and other insect pests. They may still be syringed with clear water each afternoon in common with later varieties on which the fruits are not mature. Peaches should be gathered before they are quite ripe and placed on a shelf in a well-ventilated fruit room, for if a Peach is allowed to become dead ripe its flavour deteriorates. Fruits at the ripening stage must have full exposure to sun and air, for which reason it may be necessary to remove some of the leaves or to bend them out of the way. Continue to remove the breast-wood from trees ripening their fruits and shorten those shoots that will be entirely removed when the crop is cleared. The removal of these useless shoots will not only admit extra light and air to the trees, but will assist in the swelling of the fruits. The crowding of the shoots prevents the proper ripening and growth of those that are needed for next year's fruiting; especially is this so in the case of trees growing in unfavourable situations.

The varieties are carrying good crops of fruits, and these will be especially valuable this season owing to a scarcity of Pears. As in the case of early varieties, remove any shoots that are unnecessary. Note any trees that are

making too much growth, also any that are barren, with a view to root-pruning them later, if it is considered advisable. If any of these trees have been mulched, the material should be removed, and especially if the roots are growing in a rich vegetable border. Keep a sharp look-out for earwigs, wood-lice and other insect pests, and keep them in check by the adoption of suitable measures.

Apricots.—As soon as Apricot trees are cleared of their fruits, give the foliage a thorough cleansing with the garden hose. Keep the lateral growths in check and remove any strong shoots that are not required, for it is better to prune them at this season than to do so in winter. Encourage young trees to make suitable, but not too rampant, growth. If growth is too vigorous the roots must be kept in check, and if necessary root-pruning practised early in October.

Strawberries.—Runners may still be planted, but unless they are extra strong they will not be expected to produce much fruit next season. One of the best crops to plant preparatory to Strawberries is early Potatoes, as their culture entails deep workings of the soil and the use of a considerable amount of manure. Strawberries that are planted early have a better chance of becoming established and of ripening their shoots before frosts arrive.

THE KITCHEN GARDEN.

By E. MORTER, Gardener to the Hon. VICARY GIBBS,
Aldenham House, Elstree, Hertfordshire.

Cabbages.—The principal batch of Cabbages which are intended to furnish a supply in spring, should be planted without further delay on land which has been heavily manured and deeply worked. For many years past I have cultivated the Spring Cabbages on a site previously occupied with Onions, and the results have been excellent. The surface of the ground should be broken down finely, and a good dusting of soot and wood ashes applied. Allow a distance of from 18 inches to 2 feet between the rows, varying this according to the variety; and 1 foot from plant to plant. Every alternate Cabbage can then be cut when quite young, and frequently in early spring green vegetables are none too plentiful. As a preventive of slugs, place a small portion of finely-sifted cinder ashes round each plant after the plants have been made very firm and thoroughly watered at the roots. It is an excellent practice to put a small number of the largest plants on a south border. These will generally prove valuable for cutting very early, as compared with those on the principal break; but such plants must be of a reliable variety, which is not addicted to bolting, but which is known to develop hearts at an early age. A variety which has never failed us once is *Ellam's Early*.

Coleworts are growing quickly, and will require but little further attention except stirring of the surface soil frequently with the draw hoe, and if the land is inclined to be poor, occasional applications of a good vegetable manure may be given.

Cabbagings should now be blanched as speedily as possible, adding fresh material about once in every ten days, using at the first brown paper, and afterwards hay bands. Make each plant quite secure with a stout stake, and bank up plenty of soil along the rows when completed, making sure that the plants do not suffer from want of moisture at the root.

Cauliflowers .—These are now "turning in" fast, and, generally, they are of first-rate quality. Keep the heads well protected by placing leaves over them and tying up the outer ones. Lift some of them and preserve them in a cool shed if they are becoming fit for consumption too quickly. In such conditions they will keep for many days, and their appearance and quality will improve rather than otherwise. Preparations should be made towards the end of the second week in the present month for sowing seeds of suitable varieties for wintering in cold frames. The seed should be sown thinly and broadcast on rather poor soil, and netted securely against winds.

Onions .—All the spring-sown crops, whether sown in the open or raised in heat, should now be lifted, and, after careful ripening, be stored for the winter. There are many methods of stor-

ing, but I know of none equal to that of roping and hanging up in a cool place; the work of roping can be done under cover on wet days, and every care should be taken not to bruise the bulbs, or they will be sure to suffer in consequence, especially the larger ones. Make a good sowing, fairly thick, of some silver-bladed variety in a cold frame for use in winter salads.

Capsicums and Chillies .—Those which have been growing in pits or frames should be moved to the intermediate house. Apply manure water liberally to the roots, fumigate the plants as may be necessary, and keep them as near to the roof glass as possible.

FRUITS UNDER GLASS.

By T. COOMBE, Gardener to LORD LANGRATOCK,
The Hendre, Monmouthshire.

Pineapples.—The present is a suitable time to pot suckers of the Queen Pineapple. An ample supply of suckers will be available from the plants that fruited this summer, and in selecting them, choose the strongest offsets with broad, sturdy leaves. Before potting them, remove their short lower leaves, and make a clean cut at the base. A compost of moderately moist, light, fibrous loam, broken up, and separated from fine particles, with some soot added, forms a suitable potting medium. For strong suckers, clean, adequately-drained 7-inch pots should be used, but those 6 inches in diameter will be large enough for smaller suckers. In potting, place the offsets sufficiently deep in the pots to ensure their remaining firm and ram the compost well around them. Plug the pots up to their rims—at about 18 inches apart—in a bed conveniently near to the glass and having a warmth of about 85°. The night temperature of the pit should rise from 60° to 70°, rising by day in accordance with the weather. Attention should be attended to as necessity arises, and the plants shaded from bright sunshine. Maintain a moist atmosphere, and lightly spray the plants overhead early in the afternoon on fine days. By careful attention to these details the plants will not require watering until their roots have reached the sides of the pots, when shading should be gradually discontinued.

Reovating vine borders .—In cases where vines are unsatisfactory owing to the defective condition of the borders, the present, provided the fruit has been gathered and the wood is sufficiently ripened, is a suitable time to overhaul the border. Should the vines be planted in both inside and outside borders it is advisable to disturb one border only this season, and in such cases the soil may be entirely removed on the one border, replacing it with fresh compost. The work should be done quickly. Commence by taking out a trench at the extreme end of the border, and follow this up by gradually working the soil away from the vine roots. When completed the roots should be carefully laid on one side and be protected with damp mats. First make the drainage of the borders perfect. The compost for filling in the trench should consist of good, rich loam, to which, according to its texture, has been added more or less crushed mortar rubble, wood ashes or charcoal, and crushed bones—though failing these, good fibrous loam alone will answer. The soil should be trod firmly and the roots arranged evenly in layers, the top layer of roots being close to the surface. As the work proceeds, cut away all damaged portions of the roots, shorten those without fibres, and make clean incisions along the parts left. After the soil is all filled in, lightly mulch and well water the border. Maintain a moderately close and moist atmosphere until fresh root action takes place. Shade the vines from bright sunshine and occasional syringing them with clear water.

Newly-planted vines .—In order to assist the vines to thoroughly mature their shoots abundant ventilation should be afforded, opening the front and back ventilators fully during the daytime and partly by night. If it is considered advisable a little warmth should be permitted from the hot-water pipes. Much of next year's success will depend upon the proper ripening of the wood this autumn, and this is a great measure is dependent upon healthy foliage. Therefore every endeavour should be made to keep the leaves in perfect health until they fall naturally from the cones.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens or plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. The Editor's name should be written on ONE SIDE ONLY OF THE PAPER, not on both sides, as far as possible and duly sealed. In the case of botanical specimens, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unsolicited communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, SEPTEMBER 3.—Roy, (Alderman Hort. Soc.'s Sh. in the Waverley Row, London), 10.30 a.m. to 1.0 p.m.

THURSDAY, SEPTEMBER 4.—London Dabbia Union's Sh. at Royal Botanic Society's Gardens.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—59.8°.

ACTUAL TEMPERATURES.—LONDON.—(Hedgeley, September 2 6 P.M.): Max. 65°, Min. 50°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—(Thursley, September 3 10 A.M.): Bar. 29.9; Temp. 59°; Weather—Bright sunshine.

PROVINCES.—(Wedley, September 2 6 P.M.): Max. 58° Cornwall. Min 53° Ireland, N.W.

SALES FOR THE ENSUING WEEK.

MONDAY, TUESDAY, WEDNESDAY, THURSDAY, AND FRIDAY.—Dutch Bulbs in large variety, at 67 and 68, Cheapside, E.C. 4, by Protheroe & Morris, at 10.30.

THURSDAY.—The Freehold Property, Seymour Nursery, Haldeigh, Essex, with residence, greenhouses, &c., also Freehold Land, at the Mart, Tokenhouse Yard, E.C., by Protheroe & Morris, at 2.

The Hollyhock.

Amongst the oldest of English garden flowers, the Hollyhock holds a prominent place. In the sixteenth century single and double varieties were described by Rembert Dodoens of various hues similar to the colours of varieties familiar at the present day. We may well believe that a great impetus was given to gardening following the translation of Dodoens' book by Henry Lyte in 1578, for there appeared no fewer than five editions up to 1610, including one in small 4to, abridged by William Ram and published in London. At about the same period Gerard's monumental work was published, followed by John Parkinson's *Paradisus Terrestis*. Whether these works were the result of a greater interest taken in garden flowers in this country or whether the publication of the works was responsible for the result, it is certain that we need only look through the pages of these old works to see how rapid was the improvement after the publication of Parkinson's folios in 1629.

The Hollyhock was greatly favoured. Gerard states, in his *Herball*, that it was sown in numerous gardens, and in the later editions there are plates of single and double-flowered varieties. The plants were well cultivated, as we read of them throwing up stems to the height of 10 or 12 feet, with great and double flowers of a deep red colour tending to blackness. Later, in 1665, Rea's *Flova* was pub-

lished. We have before us as we write the enlarged edition published eleven years afterwards. He states that there are many sorts of garden Mallows, "but most of them fitter for a physick than a flower garden, there being but one kind that beareth beautiful flowers, which is that called *Malva hortensis* rosea multiplex, which in English we call double Hocks, or double Hollyhocks, these bearing many gallant double flowers, and of divers glorious colours." The plant is minutely described even to the smaller green leaves amongst the fair, large flowers, the description of these double flowers being strictly accurate if applied to those of the present day. "There are some that the double flower hath many heads, as if many small double flowers were thrust together into one. The colours of these flowers in several plants are either white, silver colour, cream colour, blush, rose colour, carnation, scarlet, orange-scarlet, brimstone colour, bright red, dark blackish-red or purple, of all which several colours I have plants growing in my own garden." Rea adds: "For although the plants are of some continuance, yet they are chiefly increased and raised from seeds."

At this time the varieties with single flowers were not much favoured; probably as the pollen is so plentiful on the anthers of the single varieties, and as bees sip from the nectaries until they faint, it would be easy to fertilise the best double varieties with the pollen from those with single flowers. We can easily learn from such quotations how much we owe to the cultivators of garden flowers 250 to 300 years ago for the plants which now adorn our gardens; doubtless there were periods during which the Hollyhock, like other garden favourites, passed through seasons of neglect, or, in other words, a time when it ceased to be fashionable; but there must have been in the old days, as there are at the present day, ardent spirits who improved and cultivated their favourite flowers with no thought of what the fashionable world might think or say of their work, and so improvement went on until the present high standard has been reached.

In the middle of last century there were two distinct types of Hollyhocks in gardens, and they were designated as the English and Scotch types. The Scotch flowers were very large, with immense guard petals, and no amateur cared to improve them. The English type was very much smaller; the flowers were closely set on the spikes, with more double centres of perfect form and almost inconspicuous guard petals. An enterprising Scotch gardener, the late John Laing, who was head gardener at Dysart House, at Pathhead in Fifeshire, conceived the idea of crossing the two types, and in this he was very successful, for many good varieties were raised at Dysart, and later at Forest Hill, after having started a business there in company with Messrs. Downie & Laird. Mr. Laing's work was most carefully done, both at Dysart and Forest Hill. Of course he only took up the work that others had left, or were actually engaged in at the time. Messrs. Paul, of Cheshunt, distributed some very fine varieties raised in their nursery about 1850. The set contained Beauty of Cheshunt, with deep rose-coloured flowers; Black Prince (improved), dark maroon;

Glory of Cheshunt, an excellent variety with deep yellow flowers; Lizzie, rosy-peach; Pourpre de Tyre, dark red-purple, White Globe, and one or two other varieties. Charles Baron, of Walden, was making and mending shoes at this time, and devoting his spare time to raising and cultivating the Hollyhock. He also raised some improved varieties of perfect form, such as Walden Rival, Magnum Bonum, and Rosea grandiflora. The beauty of these flowers is still well remembered by many.

Excellent exhibits of these flowers were to be seen at Vincent Square on August 4 and at the great exhibition at Shrewsbury on August 19. They were shown by Messrs. Webb & Brand, who have for some time been carrying on the business of the late Mr. William Chater, of Saffron Walden. Mr. Chater was an eminent raiser and cultivator of the Hollyhock, some of the very best varieties having been produced in his nursery.

Hollyhocks cannot be so easily propagated as Dahlias and many other garden flowers, but it is possible to increase them in various ways. At the present time the side growths may be taken off, and the "eyes" inserted in small flower pots containing sandy soil in much the same manner as vine eyes are cultivated. It is necessary to cut out the eye with part of the stem attached, also to cut the leaf off, leaving the stalk. Each of these eyes will form a plant if placed in a closed frame. The old plants may be dug up in October and planted in a frame or potted up singly; when they start to grow in the spring the young growths may be inserted as cuttings, and they will root freely in bottom heat, or they may be root-grafted and treated in the same way as cuttings. It has been found by some that if the seed is saved from any particular variety, and if no attempt of cross-fertilisation has taken place, the plants raised will be as good as the parent plant and like it in colour. This is not invariably the case, but even if it can be stated to be a general rule, it is a great point in favour of the cultivation of the Hollyhock as a garden flower, as seedlings do not require nearly so much attention as propagated plants. The seed should be sown in June, so that good plants may be ready for planting out in September or early in October, and thus become established before severe weather sets in.

The Hollyhock may be classed amongst gross feeding plants, and if flower-spikes are to be obtained 10 or 12 feet in height the plants should be put out at distances of 6 feet apart. The soil should have been worked thoroughly at least one month previously to planting, to the depth of at least 2 feet, and 3 feet would be better still. The ground ought to be trenched, and a layer of manure placed in the bottom of the trench, and another layer at a depth of 6 inches. Hollyhocks succeed best in soil inclined to be heavy, and in such soils rich stable manure is better than that obtained from cow-houses, the latter material being more suitable for light soils, as it is more retentive of moisture. In dry seasons Hollyhocks require a mulching of short manure, and a good supply of water is essential to success.

Good stout sticks should be placed to them early in the season in order that they may not be blown about by winds. As the plants

increase in growth they must be tied up to the sticks, and as soon as dry weather sets in they may be freely syringed at night to prevent the attacks of red spider. This is a troublesome pest, and as it attacks the under sides of the leaves it is not easy to dislodge it.

The Hollyhock disease (*Puccinia malvaecium*) is a fungus which deters many persons from cultivating the plant, and it is very easily transferred from one garden to another in the same neighbourhood. At a railway station in Surrey a row of Hollyhocks with single flowers have established themselves the entire length of the platform; they are self-sown, and as no attempt is made to check the disease, every leaf is laden with it; consequently the pest is carried all over the district on the clothes of the passengers. The following specific is recommended for use against this pest: A bushel of slaked lime, a bushel of soot, and 2 ozs. of powdered sulphate of copper. The whole is mixed and passed through a fine meshed sieve, and the powder is applied by means of a sulphur distributor.

The following is a list of some of the best varieties: *Aba superba*, *Amaranth* (deep pink), *Alfred Chater* (rose coloured), *Black Knight* (improved), *Delicata* (rosy-blush), *James Allen* (claret-coloured), *Jessie Dean* (reddish-salmon), *Oliver Chater* (pink), *Peri* (cream-coloured), *Princess* (pink, shaded with buff), *Lilacina*, *Ruby Queen*, *Venus* (reddish shade of salmon), *Victor* (carmine), *Walden Primrose*, *Walden Yellow*, *Salmon Queen*.

We have selected these from a very large number of varieties. The tall spikes and well-developed flowers showed that the disease had done no material injury to them. The plants have been more free from disease this season than usual.

OUR SUPPLEMENTARY ILLUSTRATION shows a house of *Miltonia vexillaria* in the gardens at Drumlanrig, Thornhill, Dumfriesshire, one of the residences of the Duke of Buccleugh. This plant is doubtless one of the most beautiful of all Orchids. Mr. DAVID ENGLIS, the gardener, informs us that, for many years, the plants at Drumlanrig were in winter placed in the Cattleya house, with the result that the plants grew splendidly, but did not flower satisfactorily. Three years ago it was decided to keep them all the year round at the warmest end in the *Odontoglossum* house, and since then the plants have grown sturdily and flowered with freedom. The house is a span-roofed structure and is not an ideal one for Orchids, for it faces north and south, and has no bottom ventilation; great care has, therefore, to be taken in admitting air by the top ventilators. The house has the advantage of remaining very cool in the warmest weather. The plants are potted and top-dressed alternately every year. The work of potting and top-dressing is performed during August or September. The photograph was taken by the foreman at Drumlanrig with a pin-hole camera, made by a local plumber in Thornhill.

ROYAL HORTICULTURAL SOCIETY.—Mr. ROBERT SYDENHAM has offered, and the Council has accepted, prizes for bulbs grown in Moss fibre or similar material and without drainage, to be competed for on March 9, 1909. Particulars can be obtained from the secretary.

CONFERENCE ON THE SPRAYING OF FRUIT TREES.—The Royal Horticultural Society, in conjunction with the National Fruit Growers' Federation, is organising a conference on "Spraying" on October 16, the second day of the annual exhibition of British-grown fruit, at the Royal Horticultural Hall, Vincent Square, Westminster. The chair will be occupied by Colonel WARD, M.P. (11 a.m. to 1 p.m.), and Colonel LONG, M.P. (2.30 p.m. to 4.30 p.m.). Papers will be read by Mr. G. B. MASSEE, Mr. H. F. GERLING, Professor F. V. THEOBALD, and Mr. C. HAMMOND. Seats will be reserved for any person making application before October 9.

SWEET PEA CLASSIFICATION.—The Floral Committee of the National Sweet Pea Society recommends the following varieties as the best in their colours:—*White*: Dorothy Eckford, Eta Dyke, and Nora Unwin. *Crimson and Scarlet*: King Edward and Queen Alexandra. *Rose and Carmine*: John Ingman. *Yellow and Buff*: James Grieve and Paradise Ivory. *Blue*: Lord Nelson and A. J. Cook. *Blush*: Mrs. Hardcastle Sykes. *Cornic*: Chrissie Unwin. *Pink*: Countess Spencer and Constance Oliver. *Orange shades*: Helen Lewis and St. George. *Lavender*: Lady Grisel Hamilton and Frank Dolby. *Violet and Purple*: Rosie Adams. *Magenta*: Menie Christie. *Picotee-edged*: Evelyn Hems. *Fancy*: Sybil Eckford. *Mauve*: Mrs. Walter Wright and The Marquis. *Mauve and Bronze*: Black Knight and Hannah Dale. *Striped and Flaked (red and rose)*: Jessie Cuthbertson and Paradise Red Flake. *Striped and Flaked (purple and blue)*: Prince Olaf. *Bicolor*: Jeannie Gordon. *Marbled*: Helen Pierce.

BOTANICAL MAGAZINE.—The September issue contains illustrations and descriptions of several interesting plants. The first plate is a very large drawing of

RHODODENDRON MADDENI VAR. *OBTUSIFOLIA*, tab. 8212.—This differs from the type in its longer calyx segments and obtuse leaves. It forms a shrub 3-10 feet high, and although it grows on the mountains of north-east Manipur, on the eastern frontier of India, it is not perfectly hardy in this country. Mr. WATSON, who gives a short cultural description of the plant, states that it succeeds well in the Himalayan House at Kew, which is nothing more than a large greenhouse. *R. Maddenii* greatly resembles *R. Dalhousie*, a species common in gardens in this country.

ROBINIA KELSEYI, tab. 8213.—This is named after Mr. HARRIAN P. KELSEY, a nurseryman of Boston, U.S.A. It forms a shrub 3-10 feet high of a compact and distinct habit: the flowers are rose-coloured and are produced in racemes about three or four inches long. The blossoms are produced early in June, and the flowers are followed by very ornamental fruits, which are covered by reddish bristles. The descriptions of both the *Rhododendron* and the *Robinia* are from the pen of Mr. HUTCHINSON.

AGAVE WATSONII, tab. 8214.—This species forms a very short stem and produces a rosette of 15 to 20 spreading, narrowly oblong-lanceolate leaves, and these are very closely set with margin-prickles. The new specimen is the only one known in cultivation, and although it has flowered it has not produced seeds, neither have any offsets formed. Mr. DRUMMOND, who writes the description of the plant, states that it is nearest to *A. densiflora*.

ZALUZJANSKYA MARITIMA, tab. 8215.—This plant was figured on page 162 in our issue for August 31, 1907, when Mr. GUMBERTON, to whom we were indebted for the opportunity of illustrating it, stated that the seeds were sent him by Mr. THORCKROFT, Barberton, Transvaal.

The value of the plant for garden purposes seems to suffer from the fact that the blooms open only in the evening or in dull weather. The expanded blossoms, however, are very fragrant. Mr. WATSON states that the Kew plants died after flowering and failed to produce seeds.

BULBOPHYLLUM GALINUM, tab. 8216.—This species of *Bulbophyllum* is figured in the same volume of the *Gardeners' Chronicle* as the *Zaluzjanskyia* just referred to, the date being July 20, 1907, page 42. It is said to inhabit the trees in the dense jungle on Maxwell's Hill, Peak. It resembles *B. Reinwardtii* in general habit, but it is readily distinguished from that species by its two-flowered peduncle. The Kew plant was pre-empted by the Hon. WALTER ROTHSCHILD, and our illustration was prepared from a plant which flowered in Tring Park Gardens.

MIDLAND DAFFODIL SOCIETY.—The exhibition for next year is fixed for Thursday and Friday, April 22 and 23. In framing the schedule the committee have adopted the new classification drawn up by the Royal Horticultural Society with the hope that its adoption will tend to dispel any doubts as to what class or section a particular flower belongs. Any reader specially interested in Daffodils may obtain a copy of the report from either of the hon. secretaries, the Rev. JOSEPH JACOB, Whitwell Rectory, Whitechurch, Salop, or Mr. HERBERT SMITH, Tenby Street, Birmingham.

PRESENTATION TO M. PHILIPPE DE VILMORIN. The employees of the firm of VILMORIN-ANDREUX ET C^{IE}, Paris, France, assembled on the occasion of M. PHILIPPE DE VILMORIN's nomination to the order of the Legion of Honour, to present their chief with a magnificent vase by CAZIN, "Peace to Thy Fields," which attracted much attention at the last exhibition of the French National Society of Fine Arts.

HOPS.—The acreage of Hops under cultivation in Great Britain in 1908 amounted to 38,916, of which Kent is credited with 23,975 acres. The Hop industry shows a steady decline, the total acreage in 1906 being 46,732, and in 1907 44,938. Hereford cultivates 5,372 acres of Hops, Sussex coming next with 3,579 acres, which is only slightly more than Worcester's 3,353 acres.

WATER HYACINTH IN MEXICO.—The water Hyacinth, *Eichhornia speciosa*, is again spreading in Lake Chapala, Mexico. The Government of Mexico has been asked to make another appropriation of \$100,000 to be used in eradicating the pest. Lake Chapala is the largest and most beautiful body of fresh water in the southern republic. It is situated at an altitude of 5,000 feet above the sea level, and, on account of this elevation, it possesses a delightful climate at all seasons of the year. The wealthy people of the country spend a portion of each summer and winter upon the shore of Lake Chapala, and many families of the city of Mexico have homes by the lake. The country adjacent to the water is devoted to agriculture, and there is a large amount of traffic carried on from shore to shore, in addition to the many pleasure craft.

COLONIAL RETIREMENTS.—It is announced in the *Kew Bulletin* that Mr. WILLIAM FAWCETT, B.Sc., F.L.S., Director of Public Gardens and Plantations, Jamaica, and Mr. JOHN H. HARR, F.L.S., Superintendent of the Botanic and Agricultural Department, Trinidad, have retired from their respective posts. Mr. FAWCETT was appointed to the post which he has just vacated in December, 1886, and Mr. HARR took up his duties in Trinidad in March, 1887.

THE AMERICAN ASSOCIATION OF CEMETERY SUPERINTENDENTS held its twenty-second annual convention at Kansas City, Mo., on August 11 to 13. About 125 members were present at the opening session, when Mayor T. T. CRITTENDEN welcomed them to the city. The various cemeteries in the locality were visited by the members.

NATURE STUDY.—The Caxton Publishing Company have in preparation an important work, to be entitled *The Book of Nature Study*, edited by Prof. FARMER, F.R.S. The aim of the volumes is to give detailed and systematic guidance to parents and teachers in introducing children to the study and love of nature. The work will be elaborately illustrated, and will also contain a series of folding models, showing internal structures of plants and animals.

TARRED ROADS AND VEGETATION.—The Paris correspondent of the *Daily Telegraph* stated in the issue of that paper for August 27 that the Paris gardeners find that the tarring of roads results in the steady and rapid destruction of the adjoining vegetation. It has been found that, in thoroughfares where the road surfaces have been tar-sprayed, the trees die off in a very short time. As an instance, it is stated that in the Avenue du Bois de Boulogne, leading from the Arch to the wood, which was tarred four months ago, no fewer than seven of the finest trees have since died. It is stated that the vehicular traffic passing over these roads causes the tar to be thrown up in very fine particles, which, on coming into contact with vegetation, destroys it. Not merely are the trees affected, but bedding plants and even lawns are alike injured. According to the same authority, the cost of the upkeep of the flower-beds alone is ten times as expensive as when the roads were merely watered. The city authorities are, as a consequence of all this, said to be giving up the use of tar on the avenues within their boundaries. Tar-dressed and asphalted paths which are used only for pedestrian traffic have, apparently, no deleterious effects upon vegetation, otherwise it would have long ago been noticed in some of the numerous public gardens where such paths exist. Many readers will remember the destruction caused to the plants in the flower-beds on the lawns about Westminster Abbey and the Houses of Parliament through the repairing of the roads with wood some two or three years ago. Although, in this case, the damage was attributed to creosote fumes, it was somewhat similar to that reported from Paris. We notice that the flower-beds have been turfed over at Westminster, and standard Bays planted; but these are not nearly so pleasing as the flowers were.

PINEAPPLES AT TWENTY A PENNY.—At one time this fruit was cultivated to a great extent in hot-houses in this country, but owing to the large quantities received from the West Indies and other colonies the fruit can be had so cheaply that it is now grown in very few gardens in these islands. Pineapples are cheaper every year in Covent Garden Market, and fine examples are sometimes seen on the coster's barrow. They are exceedingly plentiful in Singapore, where, according to the *Agricultural Bulletin of the Straits and Federated Malay States*, large tracts of country have been cleared and planted with this fruit. Great numbers of Pineapples are also brought into the town from the neighbouring islands. The result of this immense crop is that Pines have been selling in Singapore for a cent apiece, and in the country districts at five for a cent, which is equivalent to about 20 for one penny. There is a large industry in the tinning of Pineapples in Singapore, which is principally in the hands of Chinese.

THE APPLE CROP.—As the reports published in these pages have already shown, the Apple crop in England is a very satisfactory one, but a recent visit to Mr. J. PIERPONT MORGAN'S garden at Dover House, Roehampton, disclosed such a bountiful crop as is very uncommon. The youngest hush trees, equally with the largest specimens, are perfectly laden with fine fruits, and these are as clean from insect and fungus pests as could be wished. It scarcely mattered which variety was inspected, all appeared in full bearing, and there will indeed be a generous harvest to store in the recently-erected model fruit room. We were not surprised to hear Mr. J. F. McLEOD describe the

delicate flowers the weather may be of such a character that the blossoms may develop their proper colours and thus reward the cultivator for his pains, but the risk attending such a crop in a suburban district so near to the Thames is exceedingly great.

RETIREMENT OF MR. W. P. BOUND.—We are informed that Mr. W. P. BOUND, Orchid grower to Sir JEREMIAH COLMAN, Bart., at Gatton Park, Reigate, will shortly retire from this position, to take up the business of nurseryman, seedsman, and florist. The business he has purchased is that known as the Redhill Nurseries, at 112 and 114, Station Road, Redhill. Mr.

FIG. 78.—*STAPELIA GLABRIFLORA*: FLOWERS PURPLISH-RED MARKED WITH YELLOWISH-WHITE LINES.

A, rostrum; B, ligula (magnified).

crop as the heaviest he has had during the 20 years the gardens have been under his care. The Plum trees are laden with fruit, and many of the varieties of Pears are in an equally satisfactory condition, especially the early variety known as Clapp's Favourite. Among many other good features in this excellently-cultivated garden, the collection of *Calanthes* is worthy of remark. The collection is a large one, and the plants have made pseudo-bulbs of great size and strength. As we remember these products of such careful and skilful cultivation, we earnestly hope that when the plants unfold their

BOUND has been at Gatton Park for nearly nine years, and many of our readers have witnessed the splendid exhibits of *Dendrobium* and other species of Orchids that have been made at the Royal Horticultural Society's meetings during that period. These have abundantly attested to Mr. BOUND'S cultural skill, and his success as a hybridist is equally proved by the large number of hybrids from the Gatton collection, that have obtained awards from the Orchid Committee. He will have the good wishes of a large number of friends in the new undertaking he will embark upon on October 1 next.

A COLOUR CHART.—The Council of the Royal Horticultural Society ask us to state that they have long felt the need of a chart for the international standardisation of colours, but the huge expense of producing it has hitherto deterred them from issuing it. Not long since, writes the Council, a most admirable chart, containing more than 1,450 shades of colour between white and black, was published in France at the instance of the French Chrysanthemum Society, the price in England being £1 Is. nett, and by it it is now possible to exactly recognise or describe to a friend or purchaser at a distance the precise colour of any flower. The cost of this chart, £1 1s., has been somewhat prohibitive to its purchase in the past, but by undertaking to be responsible for the disposal of a large number, the Society, we are informed, is now in a position to offer this chart to its Fellows at the reduced cost of 4s. 6d., for which price it can be obtained at the Society's offices, Vincent Square, Westminster, or it can be sent free by post for 15s.; but in all cases a cheque or postal order must be sent beforehand. The work referred to is *Le Répertoire des Couleurs*, which was reviewed in the issue of the *Gardeners' Chronicle* for May 20, 1905, p. 312.

LONDON DAHLIA UNION.—The annual exhibition of this Society will take place on Thursday and Friday, September 10, 11, in the Royal Botanic Gardens, Regent's Park, London. The secretary, Mr. E. F. HAWES, Botanic Gardens, Regent's Park, informs us that the number of entries is large and that the show promises to be a record one.

Publications Received.—*Proceedings of the Academy of Natural Sciences of Philadelphia*, Volume LX., Part I., January, February, March, April, 1908. Price 1s. 6d. nett.

NOTES UPON STAPELIAS.

(Continued from p. 169.)

STAPELIA GLABRIFLORA (fig. 78).—This is a hybrid form raised from seed on the Continent about 40 years ago. It bears some resemblance to *S. asterias*, but the inner surface of the corolla is entirely glabrous, and the lobes are not ciliate. The stems are 4 to 8 inches or more high, $\frac{3}{4}$ to 1 inch square, with concave sides and erect rudimentary leaves at the teeth on the angles, velvety-puberulous. The corolla is 3 to 4 inches in diameter when the lobes are extended, but these reflex so as to cross one another behind, and are lanceolate, long-pointed, with slightly recurved margins; the inner surface of the corolla is rugose and of a dull, purplish-red colour, darker towards the tips, and marked all over with numerous, slender, transverse, yellowish-white lines. The outer corona lobes are linear, slightly notched at the upcurved apex, with a tooth projecting from the

tips, with simple purple hairs. The outer corona of this species is quite distinct from that of all others; it varies also considerably, being sometimes formed of 10 segments, sometimes of 15, or the segments are united into a cup with 10 or more lobes. In other species the outer corona consists of five distinct lobes, which are entire or two to three-toothed at the apex, or rarely three-lobed. There is a form of *S. Pillansii* with longer and more tapering corolla-lobes than in that here figured, which will be described in the forthcoming volume of the *Flora Capensis*.

STAPELIA FLAVIROSTRIS (fig. 80).—This is a handsome species, a native of the interior parts of the eastern portion of Cape Colony. The stems are 6 to 7 inches high and $\frac{3}{4}$ to 1 $\frac{1}{4}$ inch square, with compressed angles, deeply concave sides and very small, erect, rudimentary leaves at the teeth on the angles, green, velvety-pubescent. The corolla, with the lobes extended, is 5 to 6 inches in diameter, but the lanceolate,

FIG. 79.—STAPELIA PILLANSII; FLOWERS DARK PURPLE-BROWN.

notch. The inner corona-lobes have their inner subulate and hooked at the apex, and the outer horn wing-like. The entire corona is blackish-purple.

S. PILLANSII (fig. 79).—This very distinct species is a native of the Karoo region around Matjiesfontein and Grootfontein in South Africa. The stems are 5 to 7 inches high and $\frac{3}{4}$ to 1 inch square, with flatish sides or slightly compressed at the angles, whose teeth bear small, erect, rudimentary leaves, green and velvety. The star-like corolla, with the lobes extended, is 4 to 5 inches in diameter, and entirely dark purple-brown, without markings, glabrous on the inner surface, but ciliate on the long, narrow, very tapering lobes, except at the

acute lobes naturally recurve and are ciliate with long hairs in two rows, the outer row being usually white and the inner pale purple; their basal part is dull purple with transverse pale yellow wavy lines, the apical part being entirely rich dark purple-brown, this colour forming a somewhat conical projection into the transversely-marked area; the disc is dull purplish-red, and together with the basal third of the lobes, is covered (but not densely) with erect purple hairs. The inner corona-lobes are pale yellow, shading into purple-brown at the base.

STAPELIA GIGANTEA (fig. 77).—This fine species has larger flowers than any other at present known, and not only that, but they are also

* *S. glabriflora*, N. E. Brown in the *Gardeners' Chronicle*, 1876, vol. 6, p. 262, fig. 119.
† *S. Pillansii*, N. E. Br. in *Gard. Chron.*, 1901, xxxv., p. 242, fig. 103.

‡ *S. flavirostris*, N. E. Br. in text of *S. grandiflora* var. *lincolni*, N. E. Br. in *Gard. Chron.*, 1877, vii., p. 558, fig. 85.
§ *S. gigantea*, N. E. Brown in *Gard. Chron.*, 1887, viii., pp. 654 and 659, fig. 112; *Bot. Mag.*, t. 7, 68.

the largest in the whole order Asclepiadaceæ, since they measure from tip to tip of their lobes as much as 11 to 16 inches in diameter. In growth, the habit of the plant is rather more lax than in most species, on account of a short procumbent bend at the base of the stems, which are usually 4 to 8 inches high and $\frac{1}{2}$ -inch to $\frac{1}{4}$ inch square, with much-compressed angles and small, erect rudimentary leaves at the teeth, softly pubescent, light dull green. The large star-like corolla has lobes 4 to $6\frac{1}{4}$ inches long and 2 to $2\frac{1}{2}$ inches broad, ovate-lanceolate in

Plant in Zululand, and afterwards by Gerrard near the Umvelosi River, also in Zululand. In the *Kew Bulletin*, 1899, p. 55, I gave an account of the distribution of this plant, which I now believe to be incorrect, as the Transvaal plant there referred to proves to belong to another, but closely-allied species (*S. nobilis*). The Walfish Bay locality I also believe to be erroneous, and concerning the British Central African plant, of which I have only seen shrivelled dried specimens, I am at present doubtful, it may belong to *S. gigantea*. But I have no knowledge that any

but grown in this manner it never flowered. Indeed, it is not easy to get this species to flower under cultivation in this country. It appears to require some peculiar kind of treatment; possibly if some endeavour to imitate the climatal conditions of Zululand were made it might be caused to flower more regularly. In that country the winter is the dry season and the rainy season in summer, with the maximum of rainfall at about midsummer. So, possibly, if the plant were kept in a somewhat humid atmosphere from April until the end of June, and the temperature not lower than 60° Fahr., and afterwards placed in a dry atmosphere and less (but sufficient) water given it, always with a full exposure to the sun, it might perhaps produce its flowers less spasmodically than it has hitherto done. I know from experience that under a continual dry atmosphere it rarely or never flowers, although it will grow well enough. *N. E. Brown, Kew.*

(To be continued.)

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, ante, pp. 84-90.)

(Concluded from page 161.)

WALES.

ANGLESEY.—The snow and frost on the nights of April 24 and 25, when the trees were in full flower, spoiled the crops of Plums and Pears. Strawberries have been the heaviest crop I have ever known in this district. *Wm. Pilgrim, Bodorgan Gardens, Anglesey.*

CARDIGANSHIRE.—Early Apples are a failure, but later varieties have produced average crops. There are practically no Pears, although there was a plentiful show of blossom. The flowers, however, were small and imperfect, with scarcely any pollen. Plum trees made a splendid show of bloom, but the snow which fell on the night of April 23 caused much damage, with the result that there is only an average crop. Strawberries produced the best crop for several years, and the berries were of good quality. Red and Black Currants and Raspberries are also good; but Gooseberries are under an average quantity. *H. D. Prosser, Gogerddan Gardens, Bow Street R.S.O.*

CARMARTHENSHIRE.—The crops of Pears, Peaches, and Nectarines were destroyed by frost and snow in April. Apples are better than they have been for seven years; Gooseberries are of good quality, but few in number, owing to frost in April. *A. Richardson, Dynevor Gardens, Llandovery.*

DENBIGHSHIRE.—The frost on the morning of April 24 and the continued cold and wet weather up to May 16 seriously affected the crops of Apricots, Peaches, Nectarines, and Pears, all of which, at one time, gave every promise of good crops. Apples are a very variable crop. Trees in sheltered orchards are well fruited, but others which are exposed have but few fruits. *J. Martin, Bryn Estyn Gardens, Wrexham.*

FLINTSHIRE.—Pears appear to have suffered from the cold weather experienced about the time the trees were in bloom. Apples are clean and of good quality, and the same remark applies to all small fruits. *James Bernard, Alostyn Hall Gardens, Neston.*

GLAMORGANSHIRE.—Considering the severe weather which we experienced during the last week in April, when 8, 10, and 12 degrees of frost were registered on three successive nights, with heavy hail and snowstorms, the fruit crops are far better than was expected. Apple trees generally are carrying heavy crops, and we have thinned the fruits severely, especially on young trees. The foliage is free from blight, and the fruits are remarkably clean. Pears are not numerous; the trees were in full bloom during the severe weather, and, consequently, most of the fruits were killed. The crops of Peaches and Nectarines are looking remarkably well; the trees are free from blight and bight, and they are carrying heavy crops. Strawberries have been very good, the berries being of fine quality. All kinds of small fruits are satisfactory. *R. Arthur, Margam Gardens, Port Talbot.*

FIG. 80.—*STAPELIA FLAVIVESTRIS*; FLOWERS PURPLE WITH YELLOW LINES.

Corolla and ligula magnified.

form, tapering into tail-like points; the entire inner surface is light ochreous yellow marked with transverse crimson lines and thinly covered with long, fine, erect, pale-purplish hairs and ciliate with longer hairs. The corona is dark purple-brown; its outer lobes are oblong and three-toothed at the apex; the inner lobes have a free dorsal wing and a subulate inner horn. This grand species was originally discovered by

other collectors than Plant and Gerrard have found the plant in a wild state in South Africa, and think it probable that all the specimens of it at present cultivated in South Africa and Europe are portions of the original plant discovered by Plant. It will thrive under moister conditions than many species, and I have seen specimens grown in a rich soil and a moist atmosphere with stems as much as 18 inches high,

Apple, Pear, and Plum crops are under an average quantity, but Peaches and Nectarines are satisfactory, and these trees are free from blight and in perfect health. Morello Cherry trees are laden with fine clean fruits. Raspberries, Gooseberries, Currants, and Strawberries are all excellent crops. *C. T. Warrington, Penllenger Garden, Swansea.*

MERIONETHSHIRE.—Strawberries, Raspberries, Red and Black Currants, Loganberries, and Gooseberries have all given satisfactory crops. Pears, however, were spoiled by 9° of frost on April 24. Apples bloomed profusely, but failed to set. The trees generally are free from aphid, and the quality of all fruits generally is very good. *John S. Higgins, Rhig Gardens, Corwen.*

MONTGOMERYSHIRE.—The fruit crops here are very unsatisfactory, especially after the genial late spring. Apples are patchy, being plentiful on some trees, but few on others. The same remark applies to Plums. Fruits of dessert Plums on walls are very few, but culinary varieties of Plums, also Damsons, are heavy crops. *J. Lambert, Pwys Cowlyd, Wellingpool.*

PEMBROKESHIRE.—The Apple crop in this district is good, and the fruit promises to be of good quality. Pears are an average crop. Plums set freely, and have had to be thinned. Cherry trees on walls are carrying good crops of fine fruit: Peaches set well, and promise to be of good quality. The trees have been free from fly, and very little blight is seen this year. All fruit trees have made good healthy growth. Gooseberry, Raspberry, and Currant bushes are heavily laden with good quality fruits. Strawberries were exceptionally good. Royal Sovereign being very fine. Givon's Late Prolific is carrying large berries of excellent quality. Our soil is a light loam, resting on rock, and the garden slopes to the south. *W. A. Baldwin, The Gardens, Clymchaf, Bencath.*

RADNORSHIRE.—The very severe spring frosts destroyed all our Apricots, which set abundantly, and also considerably damaged the Peaches, Nectarines, Pears, and part of the Gooseberry crop. Small fruits, with the exception of Gooseberries, are good and plentiful. *J. MacCormack, Maestnach Gardens, Glasbury, Hereford.*

9, IRELAND N.

GALWAY.—Pears, Plums, Cherries, and Strawberries were all damaged by late spring frosts and heavy hailstorms. Apples are a fair crop, also Gooseberries and Currants, both Black and Red. *Thomas Dunne, Longh Cultra Castle Gardens, Gort.*

—A disastrous snowstorm early in April nearly ruined the fruit crops in this district, as though last autumn was by some persons considered unfavourable for the formation and maturing of fruit buds, the opposite was the case, for the trees developed a profusion of blossoms. The Gooseberry crop was also ruined in some places, especially in exposed situations. *Wm. Macdonald, The Castle Gardens, Kylemore S.O.*

MAYO.—The prospects for a good fruit year were in spring all that could be desired, but owing to frost on several nights at the end of April, the crops of Pears, Plums, Cherries, and Gooseberries were ruined, especially Gooseberries. The Apple trees were not in flower, so they escaped damage, except the early varieties *R. Savage, The Gardens, Belleek Manor, Belleek.*

MEATH.—Snow and frost at the end of April destroyed the Apple blossom and greatly damaged the other fruit crops. Red and Black Currants are an extra good crop, and Strawberries were more plentiful than they have been for years. An Apple orchard of four acres, in which are a few rows of Plum trees, has produced no fruit this season. *J. B. Feen, Dunsany Castle, Drogheda.*

TYRONE.—Apples are a very heavy crop. Plum and Pear trees developed a large quantity of blossom, but the fruits in many cases failed to set owing to frosts and cold winds in April. Small fruits are all well up to an average quantity, except Gooseberries. Insect pests have not been very troublesome this year. *Fred. W. Walker, Six Mile Cross.*

WEST MEATH.—The inclemency of the weather during the latter part of April destroyed one of the brightest fruit prospects in this district for years. With the exception of Apricots, all fruit trees blossomed abundantly. Pear and Plum trees were in full blossom on April 24, 25, and

26, when a severe storm was experienced with 11° of frost. The cold ruined these crops, and even the unopened buds on Apple trees did not escape damage. *Geo. Bagie, Pakenham Hall, Castlepollard.*

10, IRELAND S.

ATHLONE.—The severe frosts in the early part of the spring destroyed the prospect of good fruit crops, especially in the case of Plums, Pears, and Cherries. Complaints in this district as regards the Apple crop are frequent: in many orchards the trees are quite bare of fruits. Gooseberries have been very scarce, having been damaged by frost in early spring. *J. Murray, Moydrum Castle Gardens.*

CORK.—The crops of Pears and Plums were promising up to May, when frosts and cold winds set in, and nearly all the blossoms were destroyed. Apples (particularly early kinds) have suffered from blight: the Gooseberry caterpillar has also done much damage. *Al. Colbert, Ahern.*

—Plums and Apricots are rather thin crops, but Apples, generally, are equal to an average season. A frost at the end of April caused many Plums to drop after they were set. Pears also were much damaged by the cold. *C. Price, Mitchellstown Castle Gardens.*

KILDARE.—The Apple crop is on the whole satisfactory, but stone fruits, Pears and Gooseberries are very scarce. This is owing to cold weather experienced on April 23, 24, and 25. Other small fruits are excellent, as was the case with Strawberries. *Fredk. Bedford, Straffan House, Co. Kildare.*

WATERFORD.—The fruit crop generally in this district is under an average quantity, the only exception being the Strawberry, which produced a full crop of good fruits. All fruit trees promised well in the spring, but frosty weather set in at a critical stage, and proved disastrous to the young fruits. *D. Crombie, Curraghmore, Portlaoine, Co. Waterford.*

WICKLOW.—The Pear crop is a total failure in this county this year, although the trees appeared promising when in blossom. The damage was caused by 10 degrees of frost early in April, accompanied by a fall of snow. Gooseberries also are a failure. Apples are of good quality. *W. Owen, Powerscourt Gardens, Enniskillen.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE LATE W MITCHELL.—It was with profound regret I read on p. 174 of the death of my esteemed friend, W. Mitchell. A man of the kindest personality, he was also a most enthusiastic and capable gardener. He had been with Mr. Willis Fleming for many years. Chilworth Manor is a somewhat remote place on the main road from Southampton to Romsey, and includes large areas of common land. The soil of the gardens is of a deep sandy nature, but Mr. Mitchell in two or three comparatively small houses, used to produce some really splendid Grapes. He will be missed at Vincent Square next month, as he will be missed, and greatly mourned by numerous show committees and friends. *A. D.*

THE GLADIOLUS.—It would seem that there is a lull of a new break in the development of this useful flower. A few years since a parcel of unflowered seedlings was received by a grower in the West of England from Messrs. Hitzler, of Stuttgart. One of these has produced a very remarkable flower. The stem is from 5 to 6 feet high, very strong and robust. The spike is somewhat loose, and the lowest bloom is set on somewhat sideways; otherwise the blooms are well placed, fronting and expanded. The colour was at first a light lavender, but the last two years the colour has deepened, until now it may be said to be a rich lilac, with a deeper shade of the same colour in the throat. But the great peculiarity of this variety is in the shape of the bloom. It is quite unlike any other Gladiolus known to the writer, and may best be described as resembling a crinum: the petals are very large, somewhat reflexed, and the whole bloom more tubular than ordinarily in the

Gladiolus. When this variety is well grown the bloom, when fully expanded, measures 5 to 6 inches across. The flowering time is in most years somewhat late: in 1905 it flowered September 9, in 1906 August 23, in 1907 September 11, and this year August 15. Owing to the drought this year, the blooms have not been as large as usual, but the early date of flowering has given it an opportunity of setting seed, which is being taken full advantage of. The present holder of this interesting variety communicated with Messrs. Hitzler respecting it, and was informed by them that, to the best of their belief, they had no specimen of this variety in their collection. Accordingly the present holder felt justified in giving it a name, and he has named it Fair Rosamund. In 1907 the same grower was fortunate enough to obtain a seedling of his own raising, which is of the same type as Fair Rosamund. This he has named Belacilla, but it will not be ready for distribution for several years. There seems, then, every prospect of a new class of Gladiolus, affording interesting novelties and pleasing variety. The writer is setting several Fair Rosamund to seed, and hopes at some future time to be able to report the result of the experiment. *P. F. F., Bristol.*

CARBOLIC ACID AS A CURATIVE FOR SEAKALE DISEASE.—Readers of Mr. Salmon's interesting communication respecting the treatment of the Seakale disease at Wye College could hardly fail to be startled on noting that carbolic acid at 8d. per pound, and applied at that rate to about "4 square feet" was so far the best remedy for the disease. Four square feet is but 2 feet square, and in a rod of ground there are some 67 such small areas. The cost of similarly dressing a square rod of Seakale ground would be at the same rate, 4s. 3d., which would amount to a large sum per acre. If, on the contrary, by "about 4 feet square" an area of 16 square feet was meant, there still be needed some 7 lbs. of carbolic acid, costing 11s. 4d. per rod area, which is practically the value of a good crop of roots. If the soil were so dressed for Seakale, how would it affect succeeding crops? Would there not be a danger of its remaining poisoned for a long time? *Enquirer.*

—I am obliged to *Enquirer* for drawing attention to a slip I made in my article, viz., in writing "pound" for "ounce," in the statement that "a pound (of carbolic acid) is sufficient to treat about 4 square feet." The strength of the carbolic acid solution was one ounce to one gallon water, and 40 gallons, i.e., 40 ounces of carbolic acid, were applied to a plot measuring 19 feet by 9 feet, or 171 square feet. One ounce therefore is sufficient to treat 4½ square feet. It is very unlikely that any bad effect would result to succeeding crops from the treatment of the ground; indeed, judging from the stimulated growth of the Sea Kale, the effect, if any, is likely to be a good one. *E. S. Salmon, F.R.S., Mycolocist to the S.E. Agric. College, Wye, Kent.*

SOCIETIES.

ROYAL HORTICULTURAL.

SEPTEMBER 1.—The weather on Tuesday last was very stormy, and very few persons attended the fortnightly exhibition, although there was a good display of flowers and some of the best exhibits of fruit that have been seen for some time past at these shows. Novelties were very numerous, and no fewer than one First-Class Certificate and eleven Awards of Merit were granted by the Floral Committee. The Orchid Committee granted one First-Class Certificate, four Awards of Merit and three Botanical Certificates. Although no award was made to a novelty by the Fruit and Vegetable Committee, there were two Gold Medals given under this section for exhibits of fruits. At the afternoon meeting of the Fellows, a lecture was delivered by Mr. Thomas H. Mawson, A.R.I.B.A., on "The History of Garden Making."

Floral Committee.

President: W. Marshall, Esq. (Chairman), and Messrs. C. T. Drury, H. B. May, H. Walker, J. Hudson, J. Green, G. Keuthe, C. Black, Wm.

Howe, J. Douglas, J. T. Bennett-Poe, R. W. Wallace, W. T. Ware, W. Bain, A. Turner, C. Pearson, Wm. Cuthbertson, W. P. Thomson, E. H. Jenkins, W. J. James, and Geo. Gordon.

Exhibits of Dahlias were very numerous. A magnificent group of these flowers, shown by Messrs. CARTER, PAGE & Co., 52-53, London Wall, London, E.C.4, was awarded a Gold Medal. The group was very complete, all types of Dahlias being represented, but the majority were Cactus-flowered, representing 120 varieties, and totalling about 2,000 blooms. All the best kinds in commerce were included in the display. The exhibit was staged with excellent taste, and was relieved with suitable ornamental-leaved species of other plants, including Kochia, Asparagus, Palms, Eulalia, variegated Maize, &c.

Another large group of these flowers was shown by Messrs. BAKER, Codsall, Wolverhampton. This firm also exhibited varieties of all the types of this flower, the background of the group being composed of the large corollate Dahlias. (Silver Banksian Medal.)

Mr. H. MORTIMER, Knowledge, Farnham, Surrey, had several new varieties of Show Dahlias, including Jasper, of magenta-rose shade, Red-cap (red), Tasmania (rose-pink), and Tom Jones (see Awards).

Messrs. KELWAY & SON, Langport, Somerset, again contributed a very choice selection of Gladioli, the spikes being very large and flowers of a variety of colours. (Silver-Gilt Banksian Medal.)

Tree Carnations as plants in 6-inch pots were shown by Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonstone. The excellent culture of the plants was a subject of comment, and they were profusely flowered. They were shown in batches of single colours, including Elizabeth (scarlet), Mrs. S. J. Brooks (white), Coronation (pink), Enchantress (bluish), Mrs. W. T. Lawson (pink), Britannia (scarlet), and The Belle (white). The spaces between the various groups was filled with choice Ferns. (Silver Flora Medal.)

Herbaceous Phloxes (*P. decussata*) were shown by several exhibitors. One of the best collections of these flowers was put up by Messrs. GUNN & SONS, Olton, Birmingham. We noticed as especially good *Le Mahdi* (lavender-blue), Dove (white, with rose-coloured eye), and Fontunii (reddish-pink). (Silver Banksian Medal.)

Mr. FRANK BRAZIER, Caterham, Surrey, put up a bank of herbaceous Phloxes, having large bunches of well-known varieties. Intermingled with them were many spikes of border Asters; although they provided greenery to the Phloxes, the plants were scarcely forward enough for the flowers to be well expanded. (Silver Banksian Medal.)

Mr. AMOS PERRY, Enfield Chase, Middlesex, had many fine heads of Phlox decussata in a collection of seasonable hardy flowers, which included most of the best things in season. We noticed brightly-flowered Pyrethrums, Pentstemons in variety, *Lilium auratum rubro vittatum*, very fine spikes of *Liatris pycnostachya*, *Asclepias tuberosa*, and a host of other choice flowers. (Silver-Gilt Flora Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C.2, exhibited many garden flowers, also Chinese Asters, *Salpiglossis*, a giant-flowered Candytuft, *Polygonum verticillatum* in fruit, bearded sprays of *Actaea spicata alba*, *Zinnias*, and *Sirritrhombus*.

Messrs. WALKERS & SIMSON, Seed-men, Tavistock Street, London, W.C., exhibited types of Chinese Asters, the best being a narrow-petalled white variety named Unicorn; Salmon Queen and Hohenzollern, a late-blooming white variety, are others of merit.

Messrs. T. S. WAKE, LTD., Feltham, Middlesex, displayed a large assortment of seasonable hardy flowers, several boxes filled with Alpine plants and vases of Dahlias. (Silver Banksian Medal.)

A noteworthy display of *Tritoeas* (*Montbretia*) was made by Messrs. WALLACE & CO., Kilfield Nursery, Colchester. They were mainly the beautiful varieties raised by Mr. Davison, of Westwick Gardens, Norwich, and embraced *Prometheus* (dark orange-red), *Norvic*, a compact dwarf-growing variety with orange-red flowers; King Edmund, a tall apricot-yellow kind; Germana and Hereward. Messrs. WALLACE also showed many beautiful

Liliums and other garden flowers. (Silver-Gilt Flora Medal.)

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, displayed a collection of ornamental Gourds, a number of annual flowering plants, and, as a separate group, an exhibit of new and interesting hardy plants, mostly of recent introduction. The annuals embraced *Zinnias*, *Marigolds*, *Scabiosa*, *Nigella*, *Lavatera grandiflora*, *Asters* in variety, *Ceropegia atrosanguinea*, *Phlox Drummondii*, and others. In the other group we noticed *Aconitum Hemsleyanum*, a climbing species with pale blue flowers. *Populus lasiocarpa*, with big cordate leaves 12 inches broad and more long; *Artemisia lactiflora*, *A. Vibernum rhytidophyllum* (in fruit), *Buddleias* in variety, *Magnolia parviflora*, *Berberis vulgaris* var. *atropurpurea*, *Antonia Wilsonii*, *Rubus flagelliflorus*, and *Rubus laciniatus*. (Silver Flora Medal.)

Mr. RUSSELL, Richmond, Surrey, showed tree ivies with gold and silver foliage, plants of large-flowered Clematis, *Ceanothus Gloire de Versailles*, *Vitis Henryana*, *V. Coignetiana*, *Elegantia* of species, *Cupressus macrocarpa*, *Lutea*, &c.

Messrs. JOSEPH CHEAL & SONS, Crawley, Sussex, showed fruiting sprays of Crabs, including the Siberian, John Downie, and Dartmouth varieties, all heavily fruited, and well coloured; *Acers* in variety and *Lupinus* were included in the group.

Messrs. JARMAN & CO., Chard, exhibited their varieties of Centaureas in white, heli-tropic and yellow colours.

Messrs. BULL & SON, King's Road, Chelsea, again displayed ornamental-leaved plants as a setting to a group of *Cattleya* hybrids.

Messrs. HIGH LOW & CO., Bush Hill Park, Enfield, London, N., showed a small exhibit of greenhouse flowering plants, amongst which were some small but excellently-flowered specimens of *Chianthus Dampieri*, *Chironia eximica*, and *Rochea falcata*.

Messrs. WELLS & CO., Merstham, Surrey, showed vases of early-flowering *Chrysanthemums* and bunches of hardy Phloxes. (Silver Flora Medal.)

FIRST-CLASS CERTIFICATE.

Ilex Pernyi.—A neat-growing and elegant species from China, distinct from any other member of the genus in cultivation. The plant forms a bush of pyramidal outline, the horizontally-disposed branches being abundantly furnished with small, glossy, green leaves. As shown, the specimen was rather more than 2 feet high. The plant should prove valuable alike for the rock-garden or for planting in isolated positions in the pleasure gardens. From Messrs. JAMES VEITCH & SONS, LTD., Chelsea.

AWARDS OF MERIT.

Gladiolus Golden Mesme.—A fine yellow, self-coloured variety, the well-formed flowers being arranged in a compact spike.

Gladiolus White Lord.—A very solid flower of ivory or creamy white tone, the blossoms being closely set in a large well-formed spike. Both from Messrs. KELWAY & SON, Langport.

Dahlia Marathon.—A *Cactus* variety of very large size; the florets are coloured rose and lawn, with a yellow base and golden-coloured tips. From Messrs. STREDWICK & SON, St. Leonards.

Dahlia Tom Jones.—A show Dahlia, having a golden colour of creamy yellow, the florets being edged and suffused with rose pink. It should prove an exhibition variety of much merit. From Mr. S. MORTIMER, Farnham, Surrey.

Tritonia (Montbretia) Norvic.—A distinct and meritorious novelty, dwarf in habit and late in flowering. The flowers are of a yellow shade, stained externally with red. The spikes are sturdy, dwarf-growing, and remarkably free in flowering, for which reasons the variety should prove an excellent bedder. Exhibited by Major PETER, Westwick, Norwich (gr. Mr. Davison).

Tritonia (Montbretia) "Hereward".—A pale or refined orange-yellow coloured variety, with widely-expanded flowers each 3 inches or more across and flat, save for the somewhat recurving tips of the petals. The spike is tall and erect-growing. The variety is an acquisition among the later-flowering varieties. From Major PETER, Norwich.

Kniphofia R. Wilson Ker.—The bold, towering inflorescences of this handsome variety are very showy and of large size, the red scarlet tone of the flowers being nearly uniform throughout the spike. From Messrs. R. W. WALLACE & CO., Colchester.

Gladiolus primulinus hybrids.—A new race, the result of crossing *G. primulinus* and *G. gandavensis*. The colours embraced yellow, pink and yellow. A characteristic feature is the hooded flowers, and it is to be hoped the hybridist will not destroy this in a desire to obtain more size. From Messrs. WALLACE & CO., Colchester.

Phlox Freizeudin von Lassberg.—A pure white variety of *Phlox decussata*, with blossoms of large size and of perfect form. The inflorescences are borne on stems about 3 feet in height. From Messrs. GUNN & SONS, Olton.

Phlox Violet.—This is best described as a deeply-coloured and much-improved "*Le Mahdi*," the flowers and the trusses being of large size. From Messrs. GUNN & SONS, Olton, near Birmingham.

Phlox aquilina Nicholsonii.—An elegant variety of the bracketed type from New Zealand, which at a short distance reminds one of a species of *Gleichenia*. It is a distinct and free-growing variety, and is said to be perfectly hardy in this country. It was shown as a basket plant, the hanging shoots being very effective for this system of culture. From Messrs. H. B. MAY & SONS, Edmonstone.

CULTURAL COMMENTARY.

Trichinium Manglichi.—A well-flowered example of this rarely-seen species. Shown by Sir TRAVEL LAWRENCE, Bart., Dorking (gr. Mr. W. BAYK).

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the chair); and Messrs. Jas. O'Brien (hon. sec.), de B. Crawshaw, H. Little, W. Boxall, Stuart Low, A. A. McBean, W. Cobb, J. Charlesworth, W. P. Bound, F. J. Thorne, W. H. White, H. A. Tracy, Gurney Wilson, F. J. Hanbury, W. Bolton, and J. Forster Alcock.

For the season there was a remarkably good display of Orchids.

H. S. GOODSON, Esq., Farlawn, West Hill, Putney (gr. Mr. G. E. May) was awarded a Silver Flora Medal for a group at the back of which was a fine specimen of *Miltonia candida* grandiflora bearing five flower-spikes, around it being several varieties of *Odontoglossum Harryanum* and other *Odontoglossums*. Among the hybrids was a plant of a fine form of *Cattleya calumnata*, an old but now uncommon variety; also *C. fulvescens superba*; a pretty hybrid between *C. Schroderae* and *C. Schilleriana*, *Laelio-Cattleya Vesla* (*C. velutina* x *L. crispata*) quantum in form of a yellow colour; *C. Cattiana*, *Miltonia Blewettii* (var. *speciosa*), *Speckbilis Moreliana*, *Brasso-Cattleya Madame Hye*, and the very handsome *Laelio-Cattleya Elva* St. Vincent. (See Awards.)

Messrs. CHARLESWORTH & CO., Heaton, Bradford, secured a Silver Flora Medal for a select group containing many fine hybrids, including *Laelio-Cattleya Lambeaue* (*L. praestans* x *C. Hardyana*), a dark form of *L.-C. callistoglossa*, *L.-C. Chloe* (*L. praestans* x *C. labiata*), a variety of good shape and fine colour, and other rare *Laelio-Cattleyas*. The best of the hybrid group was *C. Rhodia* (see Awards); others noted included a beautiful new form of *Sophro-Laelio-Cattleya "Marathon"*, which secured an Award of Merit at the last meeting, the present variety having gold-tipped sepals and petals tinged with rose, being very attractive behind the intensely deep, ruby-crimson lip.

Messrs. SANDER & SONS, St. Albans, secured a Silver Flora Medal for an interesting group, the central plant in which, *Brasso-Cattleya Madame Chas. Maron*, Sanders' variety, secured the only First-class Certificate awarded at the meeting. Around it were several fine specimens of *Vanda cerulea*, and *Cattleya Leopoldii*. *Laelio-Cattleya illuminata* is a finely-coloured hybrid. Among the species noted was the pretty small *Sigmatostalix radicans*, some good forms of *Cypripedium Fairieanum*, *Aerides quinquevulnera*, &c.

Messrs. MOORE, LTD., Rawdon, Leeds, were awarded a Silver Banksian Medal for a group which embraced *Cattleya Atlanta* variety *illuminata*, a large deep-rose flower; a selection of

Masdevallias, including *M. macrura*, *M. splendens*, *M. Reichenbachiana*, and others; *Oelogyne corrugata*, *Cypripedium Fairreanum* hybrids, the twin-flowered *Cirrihopetalum billoum*, and various other interesting species.

Sir TREVOR LAWRENCE, Bart., K.C.V.O., Burford, as usual displayed an interesting exhibit of pretty and rare species.

LT.-COL. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), sent *Brasso-Cattleya Siren superba* (B. Digbyana × C. Skinneri), a pretty, warm rose-tinted flower with light base to the lip, and the best C. Skinneri hybrid yet raised; L.C. Golden Oreole var. *triginum*, a showy yellow flower with red veining and with a deep red front to the lip; *Lælio-Cattleya episcopa*, Westonbirt variety, a large and finely-formed flower; and *Sophro-Lælio-Cattleya Danae superba*, which secured an Award of Merit.

Messrs. WILLIAM BULL & SONS, Chelsea, showed a group of hybrids in which the forms of *Cattleya Iris* were prominent.

Messrs. STANLEY & CO., Southgate, showed a selection of Orchids, including a good specimen of *Cypripedium A. de Lairese* with three spikes; two forms of *Cattleya Minucia*, two *Cyclopachia chlorochilum*, &c.

Mr. A. W. JENSEN, Lindfield, Hayward's Heath, showed plants of *Vanda cœrulea* and *V. cœrulea Jenseniana*, a rather small variety with mauve lip and mauve tinting on the petals.

R. G. THWAITES, Esq., Chessington, Christchurch Road, Streatham (gr. Mr. Black), sent three pretty varieties of *Cattleya Adula* (*bicolor* × *Hardyana*) with large and freely-produced flowers of the C. *Iris* class, and C. *Euphrasia* (*superba* × *Warszewiczii*).

A. G. GROVES, Esq. (gr. Mr. W. H. Gostling), Horfield, Bristol, showed a fine specimen of *Cypripedium Kubele grandis*, with many flowers.

Mr. G. W. MILLER, Wisbech, sent several hybrid *Lælio-Cattleyas* and a seedling *Cypripedium*.

AWARDS.

FIRST-CLASS CERTIFICATE.

Brasso-Cattleya Madam Clas Moron, *Sanders' variety* (B. *Digbyana* × C. *Harszewiczii*), from Messrs. SANDER & SONS, St. Albans. One of the finest *Brasso-Cattleyas* and infinitely superior to the original form for which Baron SCHROEDER obtained a First-Class Certificate in 1902. The new flower is much larger and of a deep purplish-rose colour with a large pale-yellow centre to the lip, which has fine purple lines at the base.

AWARDS OF MERIT.

Catatum Russellianum, from Sir TREVOR LAWRENCE, Bart., K.C.V.O., Burford (gr. Mr. V. H. White). A remarkably pretty species, very rare in gardens, and belonging to the small section not furnished with antennæ, which cause the ejection of the pollinia, but in which a part of the column is said to be sensitive and serving the same purpose. The labellum is underneath, and not reversed, as in most of the genus, and it is differently shaped. The flowers are borne on an inflorescence 1 foot long; they are transparent white, with emerald-green markings.

Sophro-Lælio-Cattleya Danae superba (C. *Harsizoniana* × S.-L. *Isela Orpetiana*), from Lt.-Col. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander). A pretty dwarf plant bearing a comparatively large flower of fine form and firm substance, the central ground colour being cream-white tinged with rose, the outer parts rose-purple. The lip is yellow with a purple-coloured front.

Lælio-Cattleya Elva, var. *St. Vincent* (L.-C. *Ingramii* × C. *Harszewiczii*), from H. S. GOODSON, Esq., Fairlaw, Putney (gr. Mr. G. E. Day). A pretty and richly-coloured variety, differing from that for which Col. HOLFORD obtained a First-Class Certificate at the Temple Show this year in the large pale-yellow blotches on each side of the labellum. Sepals and petals are deep rose colour, the lip being dark ruby-purple, changing to a lighter shade in front and with yellow yellow blotches in the centre.

Cattleya Rhoda, var. *Iris* × C. *Hardyana*), from Messrs. CHARLESWORTH & Co., Heaton, Bradford. A very handsome, finely-coloured hybrid. The original form, which is in the collection of J. GURNEY FOWLER, Esq., is of similar form to C. *Hardyana*, and has apricot-yellow

sepals and petals, but the present variety is distinctly of the shape of C. *Iris*, although much larger in all its parts. The sepals and petals are cream-yellow tinged with salmon-red; the lip is ruby-red with lighter margin.

BOTANICAL CERTIFICATE.

Catatum Imshoohtanum.—A strong-growing species with tall erect spike of greenish-yellow flowers of globular form, the opening of the fleshy labellum being in front.

Calanthe Catilia.—A little-known species imported from Java, and with some resemblance to C. *Musca*, but with larger flowers and a different-shaped labellum. The flowers are pale lavender on a white ground and with a purple spot on the lip.

Cymbidium lancifolium.—The flowers are produced on an erect inflorescence; they are white with purple lines on the petals and rose-purple markings on the lip. The above three awards were granted to Sir TREVOR LAWRENCE, Bart., K.C.V.O.

Fruit and Vegetable Committee.

Present: Jas. Cheal (in the chair), and Messrs. W. Bates, Geo. Woodward, Alex. Dean, E. Beckett, John Basham, James Vert, J. Davis, H. Parr, H. Markham, B. Allan, John Lyce, G. Reynolds, J. Jacques, J. McIndoe, John Harrison, Owen Thomas, W. Poupard, and A. H. Pearson.

A very fine red-coloured Apple, named Red Victoria, came from Mr. MILLER, of Wisbech. As a report relating to the variety had been furnished, but was not to hand, it was agreed to retain the fruits till the next meeting. The variety greatly resembled Gascoyne's Scarlet.

Mr. THOS. CLARK, Histon, Cambridge, sent a seedling red Plum named King Edward.

From Mrs. AMES, Cote House, Westbury-on-Trym (gr. Mr. W. Bannister), came good samples of Doyenne's Boussoch Pear.

Messrs. R. SMITH & SONS, Worcester, sent a seedling Plum from under glass. The Committee desired to see fruits from outdoors when ripe.

Messrs. HUGH LOW & Co. had branches of an autumn-fruiting Raspberry named *Wes's* Perpetual.

Superb samples of the Parsley-leaved Blackberry were staged by Messrs. JAS. VEITCH & SONS, Chelsea.

LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury Park, Acton (gr. Mr. G. Reynolds), sent a collection of 24 handsome fruits of Queen Pine Apples, also dishes of Sea Eagle, Princess of Wales, and Gladstone Peaches; Pineapple and Victoria Nectarine, Count Athlone's Gage, and Jefferson Plums. (Hogg Medal.)

WALDORF ASTOR, Esq. (gr. Mr. W. Cannon), Cliveden, Bucks., showed bunches of Madresfield Court Grapes. The berries were very fine, and sloe-black in colour; the bunches were cut from a two-year-old vine grown in the half of a paraffin cask. (Silver Banksian Medal.)

Messrs. J. PEEB & SONS, Norwood, staged a collection of 55 dishes of fruit, chiefly Apples. Amongst these were good samples of Norfolk Dumping, Emperor Alexander, Peasgood's Nonsuch, Stirling Castle, Loddington Seedling, Lord Suffield, The Queen, King, Lord Grosvenor, Jas. Grieve, Tibbett's Pearmain, Bismarck, Hambling's Seedling, Domino, and others. Included in the display were some good Pears and Plums. (Silver Banksian Medal.)

Messrs. CANNELL & SONS, Swanley and Eynsford, Kent, set up a collection of 26 medium-sized Apple trees in pots, all from out-of-doors. The plants were well furnished with highly-coloured fruits; not over large. Amongst the best were Charles Ross, Cellini, The Queen, American Mother, Frogmore Prolific, Red Quarrenden, and Castle Major. Fronting these were 49 dishes of Apples and 24 of Plums, with several of Pears. The best Apples were Duchess's Favourite, Yorkshire Beauty, Chelmsford Wonder, Beauty of Bath, Duchess of Oldenburgh, Lady Sudeley, Evargil, and Irish Peach. Of Plums there were five samples of Pond's Seedling, MacLaughlan's Gage, Sirke's Blue, Emperor, Prince of Wales, Black Diamond, Washington, Prince Englebert, Black Imperial, and other varieties. (Silver Knightian Medal.)

From the KING'S ACRE NURSERY Co., Hereford, came a group of superb fruit trees in pots,

one of the best yet seen in the hall. It consisted of 60 trees of diverse kinds. At either end of the group were two magnificent samples of espalier-trained Peaches. The one was Sea Eagle, carrying 68 good fruits, the tree being 6 feet wide by 4 feet in height; and the other Thos. Rivers, rather less in breadth, carrying 40 good fruits. Two vines of Black Hamburgh and Rytton Muscat, a little-known variety, but resembling Royal Muscadine, were heavily fruited. At the back were tall trees of Peaches Thos. Rivers and Sea Eagle, also Nectarines Pineapple, Spenser, and Byron. In the group were Plums Grand Duke, Late Orange, Coe's Golden Drop, Transparent Gage, and Monarch. Of Pears Doyenne Boussoch, Durondeau, Pitman's Duchess, Buerré Baltet Pere, and President Osmanville. Apples were represented by Peasgood's Nonsuch, Emperor Alexander, Gascoyne's Scarlet, Wealthy, Baumann's Red Reineite, Cellini, Worcester Pearmain, and Gloria Mundi. There were also dwarf, heavily-fruited trees of Brown Turkey and White Ischia Figs. (Gold Medal.)

Beside the above came another very superb group of fruit trees and gathered fruits from Messrs. GEO. BUNYARD & Co., Maidstone. The pot trees were less large than the preceding ones, but they were heavily fruited. There were 24 Apples, Pears, and Plums. Of the Plums, very fine indeed, were Monarch, Boulouf, Admiral, Coe's Golden Drop, Giant Prince, President, White Magnum Bonum, and Belgian Purple. Peaches included Sea Eagle and Duchess of York, Pears Triomphe de Vienne and Marguerite Marillat, and Apples Cox's Orange Pippin and Baumann's Red Reineite. Fronting these were some 50 dishes of fruits, including Plums Belle de Louvain, Oullin's Golden Gage, Monarch, and Jefferson; Peach Late Devonian; Pears Dr. Jules Guyot, Williams' Bon Chretien, Souvenir du Congrès, Marguerite Marillat, Clapps' Favourite, and Madame Treve. Of Apples, specially fine and handsome were Potts' Seedling, Gold Medal, The Queen, Lord Grosvenor, New Hawthornden, Stirling Castle, Norfolk Beauty, Grenadier, and Ecklinville Seedling. Of dessert kinds were beautiful samples of Lady Sudeley, Ribston Pippin, Hitchin Pippin, Peter the Great, Coronation, Rival, Jas. Grieve, Worcester Pearmain, Miller's Seedling, and White Transparent. (Gold Medal.)

READING HORTICULTURAL.

AUGUST 26.—The fifty-second annual summer show of this society was held on the foregoing date in the Forbury Gardens.

In most classes the competition was keen, the exhibits of fruit were especially good. Cut flowers, of which *Delphinium* predominated, were also finely shown. Vegetables are always a feature at this show, and this exhibition was no exception to the rule. The leading exhibits in the big class for vegetables were of exceptionally high quality.

OPEN CLASSES (PLANTS).

For a group of miscellaneous subjects arranged for effect in a space 12 feet by 7 feet, the premier award of a Silver Challenge Bowl was won by Mr. J. Wyman (gr. to Lady COOKE, East Thorpe, Reading), with a variety of plants all too flatly arranged. Mr. F. Johnson (gr. to G. B. JOEL, Esq., Maiden Erlegh, Reading) was a close 2nd with an exhibit having a similar fault.

Mr. W. S. Sherlock (gr. to G. W. TYSER, Esq., Oakfield Mortimer) won the 1st prize easily in the class for four Ferns with well-grown specimens, of which *Adiantum* was largely predominant. Fuchsias are always a feature at this show, reminding one of the excellent specimens shown for many years past at the Trowbridge show. For six distinct plants, Mr. J. Bright (gr. to J. FRIEDLANDER, Esq., Whiteknights' Park, Reading) was easily 1st with specimens 8 feet high, beautifully trained and profusely flowered. 2nd, Mr. F. Alexander (gr. to R. T. DARVELL, Esq., Warden, Reading).

The best six tuberous-rooting Begonias were shown by Mrs. STROSS MAXWART, (gr. Mr. W. DAGGER, Bath Road, Reading, the plants being double-flowered varieties carrying huge blossoms. In the local classes for plants were seen many interesting exhibits.

CUT FLOWERS.

For 24 blooms of show or fancy Dahlias, distinct, there was but one exhibit, that from Mr. J. WALKER, Thame, but this was of an interesting character, every bloom being excellent, and the exhibit worthily deserved the 1st prize which it received.

For twelve show or fancy Dahlias, Messrs. J. CHEAL & SONS, The Nurseries, Crawley, were placed 1st, having neat examples of popular varieties. Exhibits of single-flowered Dahlias were very fine in quality and well staged. For twelve bunches of these flowers, distinct, Messrs. CHEAL & SONS won the 1st prize easily, having such excellent varieties as Betty (new), Winona, Snowdrop, Flambeau, Kitty, Miss Roberts and Fugi San. 2nd, Mr. J. WALKER.

Cactus varieties were very numerous staged. For twelve varieties, three blooms of each, Messrs. CHEAL won easily with superb examples of Mrs. H. Shoemith, J. R. Riding, Mauve Queen, William Marshall, Ivanhoe and Helene. Messrs. CHEAL also secured the leading prize for twelve distinct varieties of Pompon Dahlias. 2nd, Mr. J. WALKER. Exhibits of Roses were numerous and good for the time of the year. The best 18 single blooms were shown by Mr. J. JEFFERIES, Cirencester. The principal prize for Gladioli was won by Mr. F. EAMES, Frome, with unnamed seedlings of merit. In the class for twelve vases of flowers of distinct kinds, Mr. W. Barnes (gr. to A. F. WALTERS, Esq., Bearwood, Wokingham) beat all other competitors.

FRUIT AND VEGETABLES was staged in considerable numbers, and the products were of fine quality.

TRADE EXHIBITS were numerous and good. Gold medals were awarded to Mr. F. EAMES for a large bank of *Phlox decussata* and a bright exhibit of other hardy flowers. To Mrs. PHIPPEN, Florist, Reading, for floral work of high quality. To Messrs. T. WARE & SON, Tottenham, for Begonias and herbaceous flowers.

First-class Certificates were awarded to Messrs. J. CHEAL & SONS for Cactus Dahlia Lusitania, and for a single-flowered variety named Betty.

BRITISH GARDENERS' ASSOCIATION.

August 29.—On this date the members of the London branch visited the gardens at Gunnersbury House and Gunnersbury Park, Acton. At Gunnersbury House the Japanese gardens attracted attention. A path leads over the stepping-stones and affords glimpses of the garden from different points of vantage. The roof and walls of the residence were gay with Tropaeolums, whilst trees in tubs adorned the terrace. The visitors were conducted through the glass-houses. The fruit garden was also inspected.

The next meeting will be held at Carr's Restaurant, Strand, on Thursday, September 10.

Obituary.

GEORGE BETHELL.—The death took place at his residence, "The Firs," South Woodford, on August 27, of Mr. George Bethell, who for many years took an active part in the horticultural world. Deceased was a Fellow of the Royal Horticultural Society, and for 38 years was a subscriber to the funds of the Gardeners' Royal Benevolent Institution. The deceased was 113 his 76th year.

GEORGE COOKE.—The American papers announce the death of this gardener, who held the position of landscape engineer to the Highway Commission of San Diego, California, on August 6, at his home in that city, at the age of 59 years. Mr. Cooke was a native of Surrey, and went to America in 1896, taking up the subject of landscape gardening, and removing to San Diego for the purpose of filling the above office three years ago.

JOHN WALKER.—We regret to announce the death of Mr. John Walker, senior partner in the firm of John Walker, Seed Merchant and Nurseryman, 7 and 8, High Street, Thame, which occurred on the 24th ult., at the advanced age of 84 years. We are informed that the business will still be conducted under the name of John Walker, Thame.

ARTIFICIAL MANURES: R. F. L. T. Scan our advertising columns.

BEECH BARK INFESTED: J. T. The white flocculent substance which you take for a fungus is the Beech coccus, an insect allied to the mealy bug. You will find that it attacks the main trunk and upper branches of the tree only, therefore if you scrub the bark with caustic alkali wash, or some other strong insecticide you will soon free the tree of the pest.

BEGONIA GLOIRE DE LORRAINE: *Anxious and Binger.* There is no disease at present in the leaves. The damage is caused by mites. Dip the plants in tobacco water.

BOOKS: A. F. The following books would be suitable for your purpose—*Gardening in Town and Suburb*, by H. H. Thomas (2s. 9d.); *The English Flower Garden*, by W. Robinson (15s. 6d.); and *Johnson's Gardening Dictionary* (9s. 6d.). These works can be had from our publishing department at the prices mentioned, post free.

CUCUMBERS FAILING TO GROW: B. B. The fruits you sent were perfectly healthy, but their growth has received a check. This may have been influenced by a variety of causes, such as fluctuations in temperature, chilling the roots with very cold water, or by exposing the shoots to cold draughts. Be careful to ventilate the house on the opposite side to where the wind is blowing.

DENDROBIUM LEAVES SPOTTED: A. B. The leaves are affected by the disease commonly called "spot" in gardens. It results most frequently through some error in cultivation, such as keeping the plants in too much warmth at night-time, affording them a too high temperature after their resting season has commenced, or watering the roots too freely after the growths are completed, and the time for resting them in cooler and drier quarters has arrived. Cut off all the affected leaves, and place such as are not actively growing in a lower temperature until the growing season comes round again.

ECONYMIUS DISEASED: *Book.* The leaves are attacked by a fungus—*Oidium*. Pick off and burn the diseased twigs and leaves, and apply sulphur as a specific, using the dry flowers of sulphur, or apply one of the sulphides, such as potassium sulphide, in solution.

FRUIT INDUSTRY: R. T. The writer was evidently referring to the plantation system of fruit cultivation, where bush trees are largely grown, as opposed to the old method of growing fruit trees as standards in orchards grazed by cattle.

GARDENING ENGAGEMENT: *Miss B.* We are afraid we cannot assist you. Insert an advertisement in some gardening paper.

GRAPES DISEASED: H. J. Your Grapes are suffering from Anthracnose, *Gleosporium ampeligenum*. Remove and burn all the diseased fruit, and do not use rich stable manure at the roots of the vines, but sprinkle the soil with a solution of sulphate of iron.

NAMES OF FLOWERS, FRUITS AND PLANTS:—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time; they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

FRUITS: J. E. M. Apples: 1, Emperor Alexander; 2, Minchull Crab; Plums: 3,

Kirk's; 4, Blue Imperatrice; and 5, Prince Englebret—W. C. M. 1, Irish Peach; 2, Worcester Pearmain; 3, Cellini; 4, Grenadier; 5, The Queen; 6, not recognised—A. Langford, 1, Beauty of Bath; 2, Irish Peach. Plums: 1, Oullin's Golden Gage; 2, Prince of Wales; 3, Smith's Orleans.—E. F. 1, Crimson Quoining; 2, Worcester Pearmain; 3, Ecklinville Seedling; 4, Warner's Seedling; 6, Jolly Beggar; 7, Annie Elizabeth; 8, Warner's King.

PLANTS: G. N. 1, *Calycanthus occidentalis*; 2, *Ercilla spicata*; 3, Specimen insufficient for determination, but apparently a species of *Actinidia*—A. *Birmingham*, 1, *Ficus Carica* (Fig.); 2 and 3, *Fagus sylvatica purpurea* (Purple Beech)—T. C. 1, *Cupressus nootkatensis*; 2, *Abies brachyphylla*; 3, *Sequoia sempervirens*—E. S. 1, *Gaultheria Shallon*; 2, *Elaeagnus pungens aurea*; 3, *Cupressus pisifera plumosa aurea*; 4, *Pittosporum tenuifolium*; 5, *Cupressus Lawsoniana lutea*; *Thuja orientalis pendula*—H. H. M. *Brycon*, 1, *Populus deltoides*; 2, *Populus alba*; 3, *Salix lucida*; 4, *Tsuga canadensis*—St. George. *Thlaspi arvense*, as far as can be determined without flowers or foliage.—W. Y. Z. 1 and 2, varieties of *Begonia Rex*; 3, *B. elchospalpa*; 4, B. *Margarite*; 5, *Calluna vulgaris* variety *alba*; 6, not recognised (withered).—G. W. *Clematis flammula* var. *rubro-marginata*—A. E. B. 1, *Spiraea canescens*; 2, *Mandevilla suaveolens*; 3, *Cotoneaster buxifolia*—J. R. M. 1, *Tecoma grandiflora*; 2, *Aspidium angulare*; 3, *Muehlenbeckia platyclada*—A. C. *Symphoricarpos Hofmannii*—Hugo 1, *Oncidium flexuosum*; 2, *Ocoteoma diaphana*; 3, *Oncidium tetrapetalum*; 4, *Aspidia lunata*—B. A. *Lochardia (Fernandezia) elegans*—H. G. *Somerset*, *Lycium chinense*—20 Years Reader. *Hedychium gardenianum*—J. L. *Doerick*, 1, *Hypericum calycinum*; 2, *Calycanthus floridus*; 3, *Hedysarum multijugum*; 4, *Colutea arborescens* (Bladder Senna).

PEACH AND TOMATO HOUSE: W. B. We advise a width of 10 feet in the glasshouse which you contemplate erecting against your existing 9 feet high wall, 120 feet in length, and intend to grow Peaches against the back wall and Tomatoes on the ground space in front. The width you mention—7 feet—does not allow enough space for the production of a sufficiently profitable crop, and the difference in the extra cost of erecting a house 3 feet wider would only be a matter of about £10. The cost of erecting a lean-to house, 120 feet long, 10 feet wide, 9 feet high at the back and 4 feet high in front would be about £85. This cost would include top and bottom ventilating lights, but is exclusive of excavations and brickwork.

PEAR LEAVES WITH BLOTCHES: A. C. & F. G. The leaves are affected with the Pear scab, *Fusicladium pyrami*. Remove and burn all the diseased leaves and spray the healthy ones with the Bordeaux mixture. In winter wash the trees with copper sulphate.

PURPLE PODED BEAN: F. H. The variety is purely a coloured podded French Bean. We have seen it exhibited under the name of Firefly.

TOMATO AND CUCUMBER PLANTS WITH CLUMBED ROOTS: H. P. Both these plants are badly infested with eelworm. It will be necessary to thoroughly destroy all the plants by burning and to well cleanse the structure in which they were grown, using carbolic acid in solution and plenty of soap and warm water. The old soil should either be baked or buried in a distant part of the garden. If possible, grow your Tomatoes and Cucumbers in another structure next year.

VINE BORDER: *Anxious.* In the Calendar this week on Fruits under Glass, directions are given for renovating vine borders.

A VILLAGE FLOWER SHOW.

FOR a number of years an exhibition of horticultural produce has been held in the grounds of Miss Willmott's estate at Warley, Essex. It is not generally known that John Evelyn, Esq., F.R.S., the author of the well-known *Diary* and of the equally celebrated work "Silva, or a Discourse of Forest Trees, and their Propagation in His Majesty's Dominions," bought the estate of Warley Magna and lived there from May 12, 1649, until September 17, 1655.

He records in his diary that on September 17 he "received £2,600 of Mr. Hurt for the Manor of Warley Magna in Essex, purchased by me some time since. The taxes were so intolerable that they ate up the rents, &c., surcharged as that county had been above all others during that unnatural war." Evelyn was passionately fond of horticulture and arboriculture, and doubtless many of the trees at Great Warley were planted by him, but he was singularly unfortunate in his gardening experiences, until he retired after a most strenuous life to his patrimony at Wotton, in Surrey. He had, as he says, to leave his gardening work at Warley owing to the intolerable taxes. He had a house and garden, with a very fine Holly hedge, at Sayes

Court, Deptford; but, unfortunately, he let his house and garden for a term to Admiral Benbow, who rented it with the condition that the garden should be kept up, but Evelyn had the mortification of seeing much of his former labours impaired there for want of a more polite tenant; but worse was to come. Benbow sub-let it to Peter the Great. Evelyn's servant wrote to him that the Czar had "a house full of people and right nasty." One of the Czar's amusements was to be trundled through Evelyn's beautiful hedges in a wheelbarrow. Possibly this was the reason that three garden wheelbarrows were included by the assessors as damaged, and had to be paid for by the patient taxpayer. The house itself must have been a perfect wreck. Sir Christopher Wren was instructed to survey the house, garden and grounds and report on the damage done by the Czar and his followers. The King's gardener, Mr.

has been eminently successful. Probably a flower show entirely made up of the produce of cottage gardens, and of the produce of the farms in the district may seem to be relatively uninteresting to professional gardeners. But the importance of the work Miss Willmott is doing in the Great Warley district cannot be too widely known and imitated. We often read of "How to bring the people back to the land." Those wishful to know how to keep the people on the land should do as is done in a quiet way here. The following are a few of the rules of this cottage gardeners' society and farm produce show:—

1. The show is intended specially for the encouragement of cottage gardening in the parishes of Great and Little Warley.

2. By cottagers are meant those who, not being professional gardeners, occupy houses of £10 or less in rateable value.

But there are 13 rules for exhibitors, such as are usual in exhibition schedules.

The important point is that every cottager can exhibit, and an inspection of the exhibition leads one to the belief that everybody does. About 70 prize-takers came up on the day of the show to receive the prizes from the hands of the President. The last to come up had won a live pig, but Miss Willmott could not find it in the basket with the other prizes. There were 120 classes for exhibitors, with from three to four prizes in each class, and the competitors were numerous. Nearly all the classes were well filled, and the produce excellent. The exhibition this year was the tenth, and the progress made in the decade is marvellous. All kinds of garden produce is exhibited, and the vegetables, such as Potatoes, Peas, Runners, Beans, Carrots, Parsnips, Cabbages, Turnips, Beets, &c., would be creditable to any practical gardener. Cut flowers and window plants were excellent. The boys and girls are encouraged as well as the father and mothers. Classes for loaves of bread, cooked Potatoes, cakes, puddings, &c., are included in the schedule, also for all sorts of sewing, ironing and needlework, knitting, patching, darning, specimens of flower-painting, map-making, and essays on botany. Seeds and plants are freely given to the cottagers. On the occasion of the show prizes are also given to those who take part in the old English games. The day of the show is a gala day in the district; the grounds are crowded with visitors who are allowed to ramble everywhere, and, needless to say, this is an education in itself. The visitors look, long and admire, but everything is untouched. The exhibitors are not asked to subscribe, but by the generosity of the President and her friends, there is generally a good balance in hand: the amount in 1907 was £25 17s., which was carried on to 1908. Doubtless there is a great deal to be done to bring the work to a successful issue. Miss Willmott is a strenuous worker herself, and she is ably seconded by Colonel Whittington, who holds the office of hon. secretary and treasurer. Before the society was founded, some of the gardens of the cottagers were like that of the sluggard.

"I passed by his garden and saw the wild briar, The thorn and the thistle grew broader and higher."

FIG. 81.—*SCILLA CILICICA*: FLOWERS BLUE, TINGED WITH VIOLET. (For text see p. 194)

George London, was called in to assist in assessing the damage to the garden. "The grass plots, bowling green and gravel walks were broken into holes. Great damages were done to the trees and plants which cannot be repaired, as the breaking of the branches of the wall fruit trees, spoiling two or three of the finest true *Philæreas*, breaking *Hollies* and other fine plants." Such was the amusement of an emperor in the good old times! It is of some interest to recall the fact that Great Warley was owned by one of the most celebrated gardeners of the time of the Stuarts, about 250 years ago, and that it is now in the hands of one of the most famous gardeners of modern days; but Miss Willmott not only loves gardens herself, she does her utmost to make every man, woman and child within the sphere of her influence take an interest in their gardens, and in this she

Now, all this is changed; the gardens are well cultivated and cropped; useful vegetables, fruit, and beautiful flowers have taken the place of weeds and disorder. There are, doubtless, many parishes where a similar work is in progress; but one cannot suppose that the people in such parishes are in any hurry to flock to the towns. There is no complaint that time cannot be found to do the work of the garden. Where there is a will there is a way. A man has been known to trench his garden plots in the darkest night

NEW OR NOTEWORTHY PLANTS.

SCILLA CILICICA n. sps.

I SEND you a photograph of *Scilla cilicica*, a new species which differs from *S. sibirica* (verna) and from *S. Hohenackeri*.

The chief value of this new species is due to its excellence as a plant for forcing, a property which *S. sibirica* does not possess in the same degree. *S. cilicica* is very suitable for early forcing, developing gradually without any check,

half the length of the flowers. Flowers, two to six, of a bright blue colour, often having a tinge of violet; of the same size and shape as those of *S. sibirica*; filaments white, threadlike, half the length of the petals (longer than *S. sibirica*), anthers slatey-blue; capsules round, 6 to 8 millimetres in diameter; three to four round seeds are developed.

The plant grows in half-shaded districts of Cilicia, in the lower mountain regions in humus soils, and should prove hardy in England. It requires during the season of growth much moisture; and as with all Oriental bulbs, it should be taken out of the soil each year. W. Steh, *Mersina, Turkey-in-Asia*.

ORCHID NOTES AND GLEANINGS.

HYBRID BETWEEN ORCHIS LATIFOLIA AND O. MACULATA

AMONG our native terrestrial Orchids, perhaps the best known is the spotted Orchid, *O. maculata*. This species is widely distributed over our bogs and meadow lands, and according to conditions of soil and locality it varies much in the colouring of its flowers, which range from a dull purple shade to pure white. The leaves are nearly always spotted with black, and they vary in the amount of spotting to a considerable extent. *O. latifolia*, on the contrary, is much more local, being limited to boggy ground. It has broad, green, spotless leaves, a leafy stem, and a large, loose spike of pale purple flowers, amongst which the long green bracts are prominent. Both species grow together in many places and seem to intercross freely, the resulting hybrids often excelling in vigour and beauty the parents. The plants comprising the group shown at fig. 82 have been growing in the same position for several years, and the clump has increased in size since it was first planted. These Orchids are somewhat capricious in flowering, for, although they bloom well one year, they sometimes will not produce any blooms the following season. This is because they are occupied in maturing their tubers for a further effort the following year. Under favourable conditions the root-stocks multiply fast. An easterly aspect, a rich moist loam, with a surface dressing of leaf-soil, and shelter from hot sun and cold winds supply the conditions best suited for these terrestrial Orchids. Seedlings appear frequently around about the old plants if the soil is undisturbed, and they also appear amongst other low-growing plants in the neighbourhood. W. Z.

FLORISTS' FLOWERS.

THE DAHLIA.

It would be difficult to find in flowers any that were more refined, more quaint, or more beautiful than were the best Cactus Dahlia blooms staged in such numbers at the Horticultural Hall, Westminster on the 3rd inst. It would be equally difficult to find in outdoor garden flowers any that offered a more abject or melancholy spectacle than these flowers when seen the next day in the Royal Horticultural Society's Gardens at Wisley. At exhibitions, presenting the most attractive appearance, they are, in gardens, the least attractive of all flowering plants. Yet what do not Dahlia growers and fanciers owe to the Cactus Dahlia? That we have in existence not only a National Dahlia Society but also a London Dahlia Union, both holding shows in the Metropolis, the one unhappily starving the other, is due to the creation of the Cactus Dahlia, for of the old Yvarezii, first shown by Mr. Cannell in September, 1879, was the progenitor, certainly home-raised have created what we saw on the 3rd inst.; flowers of such quaint but beautiful form and structure such as the first growers of Yvarezii never

FIG. 82.—HYBRID BETWEEN ORCHIS LATIFOLIA AND O. MACULATA.

with a lamp burning at each end of the trench. There are always generous spirits amongst the well-to-do who will take a pleasure in helping a man who is doing the best he can to help himself.

A man may not complain if his house is not so tidy as it should be, if he keeps his garden untidy. Some may exclaim: Is it to be all work and no play? Certainly not, but the tendency is in these days for too much play. F

so that it is possible to have the plant in full bloom at Christmas, with luxuriant leafage, and finer in appearance than *S. sibirica*. The plant will be put into commerce this year.

Bulb larger than that of *S. sibirica*, bluish-violet; leaves 10 to 20 centimetres long, of a pleasing green, 1 to 1½ centimetre in width at the end, drawn out to a blunt point. Middle nerve on the outside elevated. Flower shaft a little taller than the leaves, mostly of the same length. Stalk round, laterally somewhat compressed; bracts very small, light violet; pedicels

dream of developing. If we look at those favourites of the ancient florists, the "shows" and "fancies," large, massive flowers of wonderful form and composition, we find in them now no advance in form or structure; they have long since attained to their creator's ideals. Pompons have also, so far as form is concerned, realised perfection. As with the shows or fancies, slight variations in colour or marking may crop up, enough on which to found a

PUBLIC PARKS OF SOUTHAMPTON.

The possession of 120 acres of ground in the centre of a large town, accessible to the public at all times, is one of the best of municipal assets, and not only does Southampton own this large area of public land in the very heart of the town, but within easy reach are common lands, totalling 365 acres, over which the corporation has full control.

An elaborate statue of Richard Andrews occupies a prominent position near the principal flower-beds, the inscription recording that the monument was erected by his fellow-townsmen. There are drinking fountains at the base, but these are not now in use, as it was considered expedient in the interests of order to discontinue the water supply and to place an iron railing around the structure.

We were informed that this park was formerly the site of allotments, and that the land was acquired by the town as an open space, the council afterwards planting it with trees and shrubs and developing it, until now it contains about 50 flower-beds in addition to borders of perennial plants and shrubberies. It also contains an aviary, in which are British and foreign birds, most of them with gay plumage, a bandstand, and other appurtenances found in a public pleasure ground. An impetus was given to the planting of this land by one of the townsmen, Sir Frederick Perkins, who, during his mayoralty in 1862, planted an avenue of Lime trees through the centre of the park. These trees now form good specimens, and the avenue is one of the features of the park.

The public tramway runs past the principal entrance, and a broad path leads to Andrews' statue, which is grouped about with flowers. The lawns hereabouts are closely mown, and in the turf are numerous beds of flowers, the whole forming a design. Some of them are very large and appear effective. The tender plants have, so far, been purchased each year, and this has greatly handicapped those responsible for the decoration of the beds, there being no surplus supplies available to draw upon. But recently land has been allotted for a nursery with glasshouses, so that the floral decorations will be better provided for in the future.

The larger beds are partly furnished with ornamental shrubs, including Magnolias, Rhododendrons, Acer Negundo (which makes luxuriant growth), Roses, Yuccas, Cordylines and other plants of a decorative character. Interspersed with these are flowering plants, such as Chrysanthemum maximum, forming large clumps and flowering in profusion; Crambe cor-

FIG. S3.—VIEW IN ANDREWS PARK, SOUTHAMPTON.

named variety, but of form and development there is no advance. As much might be said of the singles, if in them perfect roundness of outline, broad, flat petals, most evenly placed, and of varied and very beautiful colouring, be furnished. It is in the old double and semi-double section commonly described as "decorative" that so far, perhaps, the best for garden decoration is found, but these are quite outside the pale of exhibition fitness, and hence find no encouragement from the societies. Probably few Dahlias have ever excelled for decorative or garden colour effect the old scarlet "Glare of the Garden," and of whites so far we have seen none better than the double pure white Emily Hoggood, which is very free in blooming. The new section of Dahlias commonly known as "Paeony-flowered," tall and somewhat loose-growing, with large, broad florets, both as single and semi-double flowers, gives bright colour in gardens under favourable conditions. They are excellent if grown amidst or behind shrubs, but in florists' quality they are as yet absolutely lacking. They, however, like the Cactus race of 20 years ago, may have a future. But old as Dahlias are as exhibition flowers, it is but too evident their culture arouses little interest amongst the masses. Whilst we see Roses, Sweet Peas, and Chrysanthemums counting their admirers, growers, and fanciers by tens of thousands, Dahlia enthusiasts are reckoned by scores only. The plants are very tender; they need great care and skill in wintering them, in propagating them, as well as in their summer culture. They have a comparatively short blooming season; they may at any moment in the autumn when in full bloom be struck down by frost, bringing only grave disappointment. If raisers, rather than wasting so much energy in producing flowers only fit for the exhibition table and to secure certificates of merit, should seek to create a new race that will bloom early and freely, so as to furnish an abundant supply of beautiful, light, graceful flowers, they will have rendered gardens good service. So far, probably the singles approach most nearly to that ideal. D.

Although the common and the parks are situated about a mile apart, they may be said to be connected, for one of the finest street avenues in the kingdom runs in a straight line between the two open spaces. The four principal parks form a series of open spaces, all distinct and known under separate names, but divided only from each other by public roadways. Thus there are Andrews, Watts, Hoglands, and Palmerston Parks in a group, the two first-named being the most important.

FIG. S4.—THE STATUE OF DR. ISAAC WATTS IN WATTS PARK, SOUTHAMPTON.

ANDREWS PARK

is so named in compliment to a townsman, Richard Andrews, who was five times mayor of the borough, and in business as a coach-builder. His grandson is the ex-mayor and the present chairman of the Public Lands Committee.

diffolia, Pentstemon, Geum coccineum, Monardella, didyma, Cannas, Carnations, Abutilons, and suitable dwarf subjects around the edges. The elegant Eulalia japonica grows with such freedom that its shoots require frequent thinning. Some of the beds are entirely planted with Roses, one of kidney shape has been planted

with these trees this year, the intervening spaces being filled with annuals and edged with a seedling Carnation named Dazzler, which flowers from June to November. A circular bed near the main gateway is filled with Paul Crampel Pelargonium over a groundwork of blue Viola, and around the outskirts are *Alyssum Königzin* Charlotte and a yellow *Viola*. The centre of the bed is occupied by a plant of *Cordylone indivisa* that was planted six years ago from a 6-inch pot: it is now about 15 feet in height. Another round bed is furnished with Henry Jacoby and Flower of Spring Pelargoniums, *Heliotrope* President Garfield, bronze and yellow-leaved Pelargoniums, and, near the edge, a band of *Coleus Verschaffeltii*. A weeping standard Rose of Lady Gay variety forms a suitable centrepiece. An oval-shaped bed is devoted to bright foliage plants, including the variegated variety of *Acer Negundo*, *Coleus* in variety, *Abutilons*, *Cannas*, *Chlorophytum elatum*, *Iresine Lindenii*, *Gœvileia robusta*, and a groundwork of *Sedum japonicum*. This formed a pleasing combination, and was very effective. A bed filled with Paul Crampel Pelargonium and white-flowered Stock edged with white *Alyssum* was also very pretty. Some distance along the path to the left is a disused bandstand. It is formed of a raised mound of earth, and is surrounded by a hedge of closely-clipped Holly. The plateau is now turfed and serves as a meteorological station, there being a good collection of instrument for recording the weather conditions. Standing on the mound, a fine view is obtained of the flower-beds and the distant parts of the park. On the opposite side is a fine weeping Beech, also a collection of Hollies. There is another mound not far away, forming a series of three terraces. It is circular in form and has been made from an old rock-garden which existed on the spot. At the top is a fountain, and the terraces are planted with *Calceolarias* and *Zonal* Pelargoniums. The whole is surrounded by a Holly hedge. A good view is obtained from here of the avenue of Limes alluded to. Radiating from Andrews' statue are four broad walks, and between each are curved oblong borders. There are numerous trees of Horse Chestnuts hereabouts, and we noticed several large specimens of the Sumach with other trees in enclosures. Two Oaks which were planted when his Majesty the King was married have grown well. Other trees include *Pinus sylvestris*, Cedars, Golden Elms, double-flowering Cherry, Almond, Snowy Mespilus (*Amelanchier canadensis*), also *Spiræas*, *Prunus* in many species, *Wegelias*, *Magnolias*, *Xanthoerax subifolia*, *Paulownia imperialis*, *Benthamia fragifera*, *Sophora japonica*, *Staphylea colchica*, *Syrax japonica*, *Iibiscus syriacus*, *Liriodendron tulipifera*, *Bambusa* in variety, *Foeniculus latifolius*, *E. radicans*, and many others.

WATTS PARK.

On the opposite side of the roadway is Watts Park, so named from the statue of the celebrated hymn-writer, Dr. Isaac Watts (see fig. 84), who was born at Southampton in 1674, his father being the proprietor of a small boarding school.

The statue of this divine stands in a setting of flower-beds, the most prominent being one representing the Arms of Southampton. It is designed with *Alternanthera* one-half, and *Mesembryanthemum cordifolium* the remaining part, which gives a dark and light portion respectively, with three circles formed by using two of the dark *Alternanthera* on the paler *Mesembryanthemum* and one vice versa. The shield is edged with *Echeverria*. The design is set in a wide ring of ivy-leaved Pelargonium 'Chas. Turner' and *Coleus Ves. haflertii*. There are other larger beds around the statue; these are planted with tuberous-rooting *Begonias*, *Calceolaria amplexicaulis*, *Salpiglossis*, which were remarkably finely flowered, *Dolalia japonica* an

finished with a suitable edging. Two oblong beds are furnished with the scarlet Dazzler Carnation, a variety raised in these parks and which is prolific in flowering. There are many *Rhododendrons* in this park and Rambler Roses. A bed has been recently planted with varieties of Penzance Briars, and until these furnish the site, *Hollies* and *Godetias* are intermingled with them. The boundaries of this park are planted with trees and shrubs in variety; the lawns are intersected by many well-kept paths, and the whole is very creditable to the park superintendent and his staff.

PALMERSTON PARK.

This also contains a statue of the person after whom it is named, the monument being erected in 1869 in memory of Lord Palmerston, the statesman, who was a burgess of Southampton. Flowers are not much grown in this open space, but there is a neat design near to the principal entrance, worked out in the form of a large star. The park contains a bandstand, and Perkins Avenue runs through its centre.

Houndwell Park is coterminous with Palmerston Park. This space is devoted to games, including cricket and football, and the council have erected a pavilion for the use of the players. There is another open space known as

NOTES UPON STAPELIAS.

(Continued from p. 185.)

STAPELIA LONGIDENS? (fig. 85).—This is a native of Delagoa Bay, and is one of the most distinct species in the genus. Its stems are $\frac{2}{3}$ to 6 inches long, obtusely four-angled, with stout, spine-like (but soft), very acute teeth $\frac{1}{2}$ to 1 inch long along the angles, glabrous, green, mottled with purple. The corolla is about $\frac{1}{2}$ inch in diameter, having a short campanulate tube, with the bottom of it raised so as to form a sort of cushion on which the corona is seated, and widely-spreading, ovate-lanceolate lobes; it is quite glabrous, and the lobes are not ciliate; the colour is pale greenish-yellow, spotted all over with dark purple-brown, the spots on the apical part of the lobes are larger than the rest and more or less confluent. The seed-pods are about 7 inches long and half an inch thick, gradually tapering into a beak, smooth and glabrous, streaked with purple on a pale ground-colour.

No other species of *Stapelia* known to me has such long, stem-like teeth as this one possesses. In *S. Woodii*, which is most nearly allied to it, they are only $\frac{1}{4}$ to $\frac{1}{2}$ inch long.

STAPELIA OLIVACEA? (fig. 86).—The very distinct species here illustrated is a native of the

FIG. 85.—*STAPELIA LONGIDENS*: FLOWERS PALE GREENISH-YELLOW, SPOTTLED WITH DARK PURPLE-BROWN.

the Queen's Park, situated at the lower end of the town, and embracing about five acres of land planted with ornamental shrubs and flowers. It contains a monument erected to the memory of General Gordon, who was born in Southampton. The main avenue through Queen's Park is the most direct way to the principal entrance to the docks and the new post office. The town council have recently acquired about six acres of disused gravel pits at Shirley, and this is to be laid out as a children's playground.

The beautiful avenue which leads to the common is planted with English and Guernsey Elms, sometimes in three rows, on either side. At one spot stands an old inn, known as the Cowlelds, which was an important stopping place for the coaches from London in the olden times. The common itself is a romantic spot, delightful in its wild aspect. It contains four lakes, one of which has been made to provide work for unemployed men during periods of distress. Two are disused reservoirs, and model yacht sailing is permitted on them; the other is on the site of an old gravel pit. In former years there was a racecourse on this common, but this has been done away with. The parks and common are in the care of Mr. Richard Lawrence, who was appointed to the position of superintendent in 1900.

dry central region of Cape Colony, where it occurs scattered over a very large area. It is easily distinguished from all others by its stems alone. These are somewhat crowded, 3 to 5 inches high, and $\frac{3}{4}$ to $\frac{1}{2}$ inch square, with very obtusely-rounded angles and a groove down each side, toothless, but with an impressed transverse line at the base of the minute erect rudimentary leaves, minutely velvety-puberulous and very smooth-looking; when grown in the shade they are greyish-green, but when exposed to full sunlight become blotched and tinted with rich deep purple. The corolla is about $\frac{1}{2}$ inch in diameter, with a shallow funnel-shaped centre and spreading ovate acute lobes, ciliate with white simple hairs; the back is puberulous and the inner surface glabrous and very rugose, pale to dark olive-green, with brown or reddish-purple rugosities. The corona is very dark purple-brown, it differs from that of most others by the long, slender, erect inner horns and short falcate-subulate outer horns of the inner corona-lobes. The odour is extremely disagreeable. This species is very sensitive to an

¹ *S. longidens*, N.E. Br. in *Gard. Chron.*, 1895, xviii, p. 323, and 1898, xxiv, p. 7, fig. 8.

over-supply of water, and during the winter months water should be given to it very cautiously, as it is easily killed by an overdose.

HUERNIA BREVIROSTRIS (fig. 87).—This pretty little species is a native of the dry interior of the eastern part of Cape Colony, chiefly in the district of Graaff Reinet and perhaps also of Somerset. The habit is very compact and dwarf, with stems 1 to 2 or, under cultivation, sometimes up to 3 inches high and $\frac{3}{4}$ to 1 inch square, with acute angles and sharp spreading teeth, glabrous, glaucous-green, marked with purple when exposed to full sunlight. The corolla is about $1\frac{1}{2}$ inch in diameter, with a globose-campanulate tube about quarter of an inch deep, slightly contracted at the mouth, whence the limb spreads horizontally and has five very acute lobes, triangular in outline, with five small teeth alternating with them—these teeth, by the way, form one of the characters by which the genus *Huernia* may be recognised—the inner surface is

three of them (*Caralluma*, *Duvalia* and *Echidnopsis*) also occur in Arabia, one (*Caralluma*) extends its range into North Africa, South Europe and India, whilst the island of Socotra has one species of *Echidnopsis* and one of the remarkable genus *Ethiocola*. Outside of this range none of the *Stapelia* tribe are known to occur. All the species grow in dry localities, and some of them in places of the most arid character. It is on this account that some of them are difficult to cultivate, and by cultivation I mean the ability to grow and flower the same plant for several years in succession. Most failures with these plants I believe to be due to the fact that the average cultivator treats them all alike, and will give as much water and the same soil to a rare and tender *Caralluma* or a *Trichocaulon* as he would to the common and hardier *Stapelia variegata*, without giving a thought as to the very different conditions under which they

however, such as certain kinds of *Caralluma*, seem to thrive best in a mixture of eight or nine parts of sand and one part of loam; *Pectinaria saxatilis*, *Tavaresia* (*Decabelone*) *Barklyi*, and *T. elegans* and *Duvalia polita* have thrived with me in the latter mixture. Most (but not all) of the species can readily be propagated from cuttings. For this purpose the branch selected should be cut off as close as possible to its origin from the branch that gave it birth and then laid upon a shelf in full sunlight for a few days until the wound has thoroughly healed and a good thick skin formed over it; if the cutting shrivels somewhat, it will take no harm, but will probably produce roots more quickly than if it had not done so. *Stapelia* cuttings should never be planted in the soil, but merely laid upon it and pegged down steadily without bruising them; if it is an erect-growing kind, the basal part is usually more or less curved, and this part should be pegged down and the upper part supported by a stick. Temperature and moisture are two very important points in the treatment of these plants and have to be carefully attended to. Except during the hottest and driest weather, they do not thrive out-of-doors in Britain, and it is better to keep them under glass; if well exposed to the sun they do not require artificial heat during the summer, but during the winter the temperature at night ought not to be lower than 49° or 50° Fahr., and may rise, with advantage, during the day to 60° or 65° Fahr. The watering of these plants is somewhat of an art; if possible, at no period of the year should the soil be kept really wet, the most suitable condition is that when it is about as moist as garden earth is on a hot summer day just below the dry surface soil, which, although moist, will crumble easily between the fingers. If the soil should by chance get too wet or somewhat sodden, especially during the winter, it is better to place the pot in a dry place and give it no more water for at least a week, and when the soil is dry repot the plant in fresh earth. In winter they require very little water. I have found that about half a cupful once a week or once a month, according to the species, is quite sufficient.

Many kinds bear striking or interesting flowers that render them well worth cultivating, but among those that are most attractive and are more or less odourless or give forth no very strong odour, at least not perceptible at a short distance from the nose, or which only last for one or two days, the following may be mentioned, although they are not all at present in cultivation: all the species of *Hoodia* and *Tavaresia* (*Decabelone*), most species of *Huernia*, *Stapelia pulchella*, *S. variegata* var. *pallida*, both with pale yellow flowers dotted with dark purple-brown; *S. namaquensis*, with rather large flowers, having a very rough surface and a large solid-wooden annulus (shaped somewhat like a wooden curtain-ring) on the disk, light yellow, with purple-brown spots; *S. erectiflora*, with numerous, small, purplish-grey flowers, somewhat resembling a Turk's cap raised upon very long erect pedicels; *S. glanduliflora*, with elegant flowers of a light sulphur-yellow, dotted with crimson and covered with erect, clavate, white hairs, having a rather neat and dainty appearance; *Duvalia Cordroyi*, with olive-green or purple-brown flowers, adorned on the elevated disk with long felt purple or mauve-coloured hairs; and *Plectranthus compactus*, with small, erect, white, procumbent flowers, prettily dotted with purple-brown. The two species of *Ethiocola* have not yet been introduced into cultivation, but judging from their dried flowers, they must be very remarkable plants, one of them having flowers somewhat of the shape of and nearly as large as a snail and handsomely marked. It is a native of Somaliland, so if it is ever introduced, very great care should be taken not to overwater it. *N. E. Zeyher*.

FIG. 86.—*STAPELIA OLIVACEA*: FLOWERS OLIVE-BROWN.

minutely papillate, but otherwise glabrous, and the lobes are not ciliate, pale sulphur-yellow, thickly covered with small blood-red spots and the bottom of the tube entirely blood-red. The outer corolla-lobes spread on the bottom of the corolla-tube, they are black, with a velvet-like surface; the inner corolla-lobes have short erect subulate tips, and are purplish, dusted with yellowish. Like several other species of *Huernia*, the neatly-coloured flowers have very little or no odour, and have a very pleasing appearance. The plant flowers very freely, as on a small plant in a pot not more than 3 inches in diameter, I have had as many as a dozen flowers open at the same time.

CULTIVATION.

Most of the genera belonging to the *Stapelia* group are natives of South and Tropical Africa;

H. brevisrostris in *Gard. Chron.*, 1877, vol. p. 790, fig. 121; *Bot. Mag.*, t. 6373.

grow naturally. They are a group of plants which, like *Orchids*, require a special kind of treatment, for the conditions under which some kinds will thrive, or at least exist, for years are fatal to others. With regard to soil, some will grow well in any light soil, but when it comes to the production of flowers, my experience demonstrates that that is quite another matter, for I have found that whilst one kind will grow and flower well in ordinary garden soil, another will grow well but flower very sparingly or not at all in the same medium, whilst a third will neither thrive nor flower in it. From this it is evident that such soil does not supply all the conditions necessary to their well-being under our artificial conditions of cultivation. The soil I have found to suit in most cases is composed of five parts sandy loam, five parts sand, one part old mortar (powdered), and one or two parts of broken brick. Some species,

NURSERY NOTES.

SUTTON & SONS, READING.

A RECENT visit to this famous nursery firm proved enjoyable and instructive. To the amateur the rapidity with which large specimens are produced by high culture is very remarkable. Recently, for instance, a series of houses were filled with many hundreds of beautiful plants of *Cloxinias*. Although the seeds were mostly sown early in April, the plants had developed into grand specimens with magnificent blooms of practically endless variety, some delicately spotted with intense colours on light grounds like some of the finest *Calceolarias*, others of pure white, others of delicate shades of red from pale rose to deepest crimson or pale blue to intense purple with almost every intermediate grade. Her Majesty, with snow-white flowers of great substance, was undoubtedly the best of the whites, and on enquiring as to its history it was interesting to learn that 14 years were occupied in fixing the strain, which now comes true and constant from seed. Seven of these years were devoted to eliminating the last traces of spotting or tinting which characterised the strain whence it was derived. Empress of India, a dark purple form, was the best in that tint, and Sutton's Crimson the choicest of the red-coloured varieties. These and many others belong to the firm's "Giant" strain, which is characterised by large flowers of great substance and convex handsome leaves of the crassifolia type. The flowers of the variety Ditches of York are coloured purple with white edge and spotted throat, those of Duke of York are crimson on similar lines. Amongst the new breaks pointing to fresh types I noticed several in which the marginal lighter tint common to many of the varieties was sharply defined instead of being, as hitherto, shaded off, as it were, into the main tint of the flower. This is a great improvement, and in one plant the edges of the lobes of the corolla were prettily curled upwards at the base of the lobes, a feature which, when more fully developed, would give additional charm to the usually flat petals. Other houses were filled with tuberous-rooting *Begonias*, both single and double-flowered, all fine specimens, and only six months' growth from the seed. There were batches of scarlet, crimson, yellow, and white flowers, a number displaying also the peculiar feature of creasing, or rather a sort of rufescence on the petals, which, when regular, has an extremely pretty effect. Fringed forms and Picotee-edged varieties were also in evidence, while the size and form of the blooms would be difficult to surpass. To re-assert the comparative insignificance of the flowers of the wild species from which they have been developed is to recognise that the tuberous-rooting *Begonia* of to-day represents one of the great triumphs of selective hybridisation and cultivation. The starting point in this case was afforded by two small-flowered species of by no means brilliant colouring, but which, when brought together by the hybridiser, has resulted in a race having flowers six inches or even more across, accompanied by practically all the colours save blues and purples. A third species, *B. socotrana*, with small flowers in loose bunches, was then brought in as a third factor, and many handsome forms, peidulous and winter-flowering were the result, though these naturally did not figure in the groups of tuberous *Begonias* I saw. My next visit was to the extensive beds of China *Asters* in the open, which were just developing into sheets of rich colours of innumerable varieties. Many of them were dwarf forms of the comet or striped section, each petal being margined with rich red, indigo blue and other tints with white centre, and the Victoria strain on simpler lines. The impression given by this collection was that a display of such brilliancy, attainable by sowing seed in

March, should entitle them to a place in every garden.

Tomato plants in great variety, all heavily fruited, were noticed in the open. The vigour of all the varieties, the abundance and fine quality of the fruit proved clearly that, save for forcing purposes, glass is by no means essential for successful Tomato culture. *Chas. T. Drury, F.M.H., F.L.S.*

The Week's Work.

THE FLOWER GARDEN.

By W. FYFE, Gardener by Lady WASTAGL, Lockinge Park, Berkshire.

Transplanting trees and shrubs.—In planting new shrubberies a good effect is produced by placing the plants in large or small masses. Before the work is attempted see that the natural drainage is efficient, for few trees or shrubs will succeed where the subsoil is not sufficiently porous; make preparations for planting beforehand, and if large specimen trees or shrubs are to be shifted it is advisable to cut a trench in the soil around and partially underneath the roots, at least 12 months before transplanting. In cutting this trench care must be taken not to injure the young roots; they should be relaxed in the trench and covered with the finer soil.

and keep the frame close and shaded during the day, for the first week after planting, but afterwards admit plenty of air, removing the lights entirely on favourable occasions.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The Dewager Lady NUNBERGHOUS, Water Hearty, Yorkshire.

Autumn fruiting Raspberry.—The fruits will soon be ripening, and in the case of plants growing in light, poor soils applications of liquid manure will greatly assist the swelling of the berries. Protect the fruits from birds, and remove any growths that are not required, so that those that remain may have the full benefit of the sunshine. Summer fruiting varieties should have the old canes cut away, also any of the weaker newer ones. The shoots will be benefited by liberal doses of liquid manure. Secure the strongest rods to wires or stakes so that they may not be damaged by strong winds.

Mulberries should be gathered before they are fully ripe if they are required for botting, and care should be taken that they are gathered when quite dry. Mulberries are greatly appreciated by some persons when ripe for Cessert. They are also very agreeable when mixed with Apples in tarts or with Apple jelly. Birds destroy many of the best fruits, but old trees generally produce sufficient for all purposes. When clearing out sewage tanks the contents, well diluted may be placed at the roots of these trees.

FIG. 87.—*HIERONYMA BREVIROSTRIS*: FLOWERS PALE GREEN, WITH PURPLISH SPOTS.

A, front; B, side view of corolla; C, rostrum (enlarged).
(For text see p. 197.)

When fibrous roots are plentiful the specimens may be shifted with a comparatively small ball of earth. Plants removed from a damp situation to a high and dry site seldom do satisfactorily. Care must be taken to injure the roots as little as possible in transit, and in planting they should be laid out straight and afterwards covered with fine soil made moderately firm and well watered. When planting is finished the roots should be mulched and the shoots made secure from damage by winds. At no season of the year is the ground in a better condition for transplanting trees and shrubs than at the present time; the temperature of the soil during early autumn is favourable to the production of new roots, so that the injury and check caused by transplanting is soon made good, and the tree becomes re-established again before winter arrives.

Violets—Plants intended for winter flowering in cold frames, that have formed strong crowns, should be lifted with good balls of earth attached to their roots and planted about 1 foot apart each way with the foliage as near to the glass as is possible. Soil from old *Cucumber* frames mixed with sifted road grit or mortar rubble is very suitable for *Violets*. Damping causes the greatest trouble amongst *Violets* in winter; hence the advantage of growing them in a porous soil. Water the plants thoroughly

General remarks.—All milkings should be removed from trees this month so that sun and air may exercise their influence on the borders. Lightly fork up the surface soil, and more especially the ground that has become hard by treading near wall trees. Continue to gather Apples and Pears as they mature, examining the trees every few days for the purpose. Dessert varieties of Plums should also be examined at short intervals for gathering, unless these fruits are protected from the birds and wasps the best ones will quickly be destroyed. Walnuts, too, should be gathered as soon as they will part freely from the husks. When gathered they should be placed on a damp floor to keep them in a moist condition. Cobs and Filberts should be gathered as soon as the kernels turn brown and be thoroughly dried before being stored. Squirrels must be guarded against or these little animals will quickly remove a large quantity of the nuts. Fruit trees that are still infested with American blight or other insect pests should be attended to, and every effort made to thoroughly cleanse the branches with some insecticide before the pests descend into the ground for hibernating during winter. If the trees are large, spray them with the No. 2 fluid previously recommended as soon as the fruits are gathered. Two syringings with this specific completely destroyed the Pear slug worm on our trees. The hoe should be freely plied to keep weeds in check.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq.,
Rye, Peabrook, Kent.

Cineraria.—The seedlings are ready for shifting into larger pots, as they are making rapid growth and require plenty of root room. Use a similar compost as was advised before. Guard against aphides and other insect pests, and on their first appearance fumigate the house. Any of these plants that are required for large specimens will require another shift after this potting. As autumn advances Cinerarias should receive less shading, and be placed in a south aspect in an unheated frame on a bed of ashes until frost makes its appearance.

Herbaceous Calceolaria seedlings should be pricked out into boxes, the same as was described for Cinerarias, and placed in a close shaded situation. When ready they should be potted into 4-inch pots. See that the receptacles are quite clean, or when turning the plants out again for their final potting damage will be done to the roots. Slugs are very fond of young Calceolarias, therefore they must be guarded against. Apply water with care, for they must not be kept over damp, especially after they are potted into 4-inch pots, though they need sufficient to prevent the roots from becoming dry. Calceolarias enjoy a rich soil. When potting the seedlings do not press the soil too firmly in the pots. As these plants are susceptible to attacks of green fly, they must often be examined for this pest and be fumigated directly it is found. No other place suits these plants better than an unheated frame, where they should be stored on ashes until November or December, after which it is better to place them in a structure where they can be allowed a little free heat.

Schianthus.—Plants intended for flowering early in spring should now be potted into 4-inch pots and be placed in an unheated frame close to the glass. Use a light, rich soil with plenty of leaf-mould incorporated with it, for their potting. See that the pots are quite clean when they are used.

Gloriosa.—Any specimens that have become unsightly by reason of their leaves fading should be taken down from the trellis, and have the shoots wound round a stake placed in the pot. They should be placed in some water, out-of-the-way place where they may ripen their tubers. Water must now be withheld almost entirely; when the plants are ripened, lay the pot on its side in a stove during the winter.

Cladodendron Balfouriana.—Plants that flowered early in the season are now showing signs of rest. Water should therefore be sparingly given until, when the leaves have all fallen, it should be withheld altogether. The plant needs wintering in a stove temperature and given an occasional watering, just sufficient to keep the wood from shrivelling.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchard Grower to Lt.-Col. G. L. HOLBORN, C.V.O., C.I.L.E., Weston, Gloucestershire.

Cypripedium seedlings.—The present is a favourable time for affording larger receptacles to small plants that are root-bound, as the cool, moist atmosphere will favour a quick growth and free root action. Specimens that are nearing the flowering stage should be given a little more fibrous loam in the rooting medium. Seedlings that are large enough may be shifted from the seed beds. These may be pricked out into 2½-inch pots, placing several in each pot. Employ plenty of material for drainage purposes, and as a rooting material use equal parts of clean chopped Sphagnum-moss and fibrous peat, from which all the finer particles have been shaken out. Fix the seedlings moderately firmly in the compost, and keep them well shaded and frequently sprayed overhead.

Caloglyphis cristata and its varieties are now growing and rooting freely; therefore healthy, established plants will need copious supplies of water at the roots until the growth of the pseudo-bulbs is complete. At this stage, weak liquid farmyard manure applied twice weekly will prove beneficial to well-rooted specimens. Plants that were newly potted this year will require care in watering, as the new rooting material is very retentive of moisture, and will keep wet much longer than the soil to become sour and sodden. Admit plenty of light and air to these plants to ensure the pseudo-bulbs becoming

firm and well ripened, which is essential to the production of fine flowers.

Pleione have finished their growth for the season, and, with their leaves fast decaying, the roots will require scarcely any water. The species *P. humilis* is always a little later in maturing than the others, and this will therefore still need a moderate supply of moisture; the underside of the leaves should be frequently syringed in order to dislodge any red spiders that may be present. As Pleiones commence pushing their flowers immediately after the completion of the season's growth, the rooting material should not be allowed to become dust dry, but should be kept moist until the flowering season is over.

Dwarf-habited Odontoglossums.—Small-habited species in the cool house, such as O. Rossi, O. (Erstedii), O. Cervantusii, and the natural hybrids, O. Humeannum and O. aspersum, are now growing anew. There should therefore be no deterring in attending to the repotting or top-dressing of these plants, carrying out the principles advocated in last week's Calendar. These plants grow best when suspended from the roof rafters, and well-drained pans are the best receptacles for them. In common with all other newly-potted plants, these are best stood on the stage until the roots are active, as the compost does not dry so quickly on a stage as when the plants are suspended. Occasional watering will suffice to keep the soil in a sufficiently moist state. Established plants may be given a more liberal treatment, but excess of moisture at the roots should always be avoided. This is especially the case with O. (Erstedii), a species soon injured by over-watering. Even when the pseudo-bulbs are approaching the time when much moisture is needed, the compost should be allowed to dry out before giving a fresh supply of water.

Cochlidia.—The species *C. Nozliana* and *C. vanda* have desirable inmates of the cool house for flowering in spring. The plants are of small growth, and, culturally, their requirements are similar to the *Odontoglossums* referred to above. If necessary, new rooting material may be given to any of the plants that are growing actively; but as they dislike root disturbance, repotting should only be done when it is absolutely necessary.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGLATTECK, The Hendre, Monmouthshire.

Root-pruning and lifting Peach trees.—Trees of Peaches and Nectarines that have made unduly strong, or weakly growths, or that have produced fruits with split stones, should, immediately before the leaves fall, be attended to at their roots. Young trees especially often make gross shoots, and whilst this is the case they cannot be brought into a satisfactory bearing condition. The border should be in a moderately moist state before it is disturbed, and the work should be commenced by taking out a trench, with as little injury to the roots as is possible. The roots should be carefully coiled back, moistened, and covered with damp mats, and then, if necessary, the drainage, whether pipes or rubble, should be seen to, and be covered with thin turves. Over these should be placed a hest compost sufficient to rather more than half fill the vacant space. The roots should next be seen to; any requiring it should be shortened, whilst all suckers and damaged ends should be removed by means of a clean cut. Relay the roots in layers through the upper part of the border, keeping some of the fibrous ones quite near to the surface. The compost should consist of calcareous loam, to which has been added more or less, in agreement with its texture, crushed mortar rubble, wood ashes, or burnt soil. The soil should be moderately dry when it is used, and be well firmed by treading as the work proceeds. As soon as the trench is filled in, apply a mulching of manure litter, and give enough water to wet the border thoroughly. For a week or two, that is, until the trees have partially recovered the check, protect them from bright sunshine and draughts, whilst the leaves, branches, and stems should be moistened occasionally during the day with the syringe.

Late Peach house.—Late varieties, such as Thomas Rivers, Late Devonian, Exquisite, Princess of Wales, Nectarine, Sea Eagle, and

Thames Bank will still be furnishing a supply of fruits. If wasps are troublesome, they should be prevented from entering the house by the means of hexagon netting. As soon as the fruits are all gathered, carefully examine the trees, and cut out all wood that will be of no further use, chiefly that which has carried this year's crop of fruit. This will give next season's fruiting wood increased sunshine and air, and thus assist it to mature. Should it be found that too many young shoots have been left, thin them to 5 inches or 6 inches apart. Syringe the trees daily to keep the leaves free from dust and red spider; keep the ventilators fully opened both by day and night; thoroughly moisten the inside borders, and also those out-of-doors if they are dry. Weakly trees should be assisted with doses of diluted liquid manure, or be top-dressed with some suitable artificial manure. If the wood is not ripening satisfactorily, keep the atmosphere of the house warm and dry, but avoid a close, moist condition.

THE KITCHEN GARDEN.

By E. JACKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Mushroom beds should now be made both in the Mushroom house and in the open. Endeavour to collect the materials for the bed when in a fresh condition. Do not separate all the straw from the droppings, but simply the longest pieces, as by employing a reasonable amount of short litter the beds will last longer in a better condition and continue to bear for a much longer period than when droppings alone are used. Whenever possible an open shed should be used for turning and preparing the manures, which should be placed in a layer 2 or 3 feet deep, and be turned every morning for the first week or so. When working the heap take care to place the manure from the outside of the heap in the centre, and vice versa. As the temperature of the litter begins to decline the heap will need turning less often, and it may be placed closer together. When it is well fermented prepare the beds, placing the manure as firmly as possible. Insert the spawn when the warmth is about that of new milk. Beds formed in the open should be made ridge-shaped, and almost any out-of-the-way site may be selected for them. These beds cannot be made too firmly, and the ground at their base should be elevated sufficiently for water to quickly drain away. After the spawning and soiling is completed place some long stable litter to a depth of 12 inches over the bed, and though it is possible one may have to wait some considerable time before the crop appears, there need be no fear as to the results if these methods are carried out and trustworthy spawn is used.

Beds in bearing.—Much less difficulty will now be found in supplying the table with good Mushrooms. Always gather the Mushrooms with a twist; never cut them. Give a thorough soaking to the bed with good farmyard liquid manure after a number of Mushrooms have been gathered.

French Beans growing in pits and frames will need supporting with small stakes. Ventilate freely during the morning when the weather is favourable, but syringe and close the ventilators early in the afternoon. During cold nights the lights should be well covered with some protective material. Make a sowing of *Ne Plus Ultra* or *Canadian Wonder* in 7 or 8-inch pots, which should be well provided with drainage. The compost should consist of two parts fibrous loam, one part old Mushroom-bed manure, and one part leaf-soil. Germinate the seeds in a gentle heat, and immediately the young growths appear elevate the pots on shelves near to the glass and do all possible to promote a stout, sturdy, clean growth. Frost may now appear at any time, and where late crops are in full bearing on a south border it will be wise to afford them some protection whenever frost is apparent. Keep a reserve supply of picked Beans, arranging their stalks in a little water in a cool place.

Parsley.—There is yet time to make one more small sowing of this vegetable in a cold frame at a distance of about 9 inches from the glass. Late sowings in the open can now be thinned and the surplus plants pricked out into 4½ inch frames.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, SEPTEMBER 14—
United Hort. Ben. and Prov. Soc. Com. meet. Nat. Chrys. Soc. Com. meet.

TUESDAY, SEPTEMBER 15—
Roy. Hort. Soc. Coms. meet. British Gard. Assoc. Ex. Council meet.

THURSDAY, SEPTEMBER 17—
Nat. Rose Soc. Autumn Sh. at Roy. Hort. Hall, Westminster.

SATURDAY, SEPTEMBER 19—German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last fifty Years at Greenwich—57.3°.

ACTUAL TEMPERATURES.—
LONDON.—*Tuesday, September 9 (6 P.M.):* Max. 65°. Min. 54°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, September 10 (10 A.M.): Bar. 29.8; Temp. 58°; Weather—Bright sunshine.

PROVINCES.—*Tuesday, September 9 (6 P.M.):* Max. 57° Cornwall; Min. 47° Scotland, N.

SALES FOR THE ENSUING WEEK.

MONDAY—
Twenty-third great Annual Unreserved Trade Sale of Pot Plants, by order of Messrs. H. B. May & Sons, at Dyson's Road Nurseries, Upper Edmonton, by Protheroe & Morris, at 11.

MONDAY, TUESDAY, WEDNESDAY, THURSDAY, AND FRIDAY—
Dutch Bulbs in large variety, at 67 and 68, Cheapside, E. C., by Protheroe & Morris, at 10.30.

TUESDAY—
Great Annual Trade Sale of Winter-blooming Heaths, Ac., by order of Messrs B. Maller & Sons, at Burnt Ash Road Nurseries, Lee, S.E., by Protheroe & Morris, at 11.

WEDNESDAY—
Great Annual Trade Sale of Winter-flowering and other plants by order of Mr. J. Fraser, at the Nurseries, South Woodford, by Protheroe & Morris, at 11.
Tree Ferns, Azorean Lilies, Bulbs, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 5.

THURSDAY—
Twenty-seventh great Annual Trade Sale of Winter-flowering Heaths and Ferns by order of Messrs. H. Evans & Sons, at Longlands Nurseries, Sidcup, by Protheroe & Morris, at 11.

FRIDAY—
Second Annual Trade Sale of Aspid-tras, Palms, &c., by order of Mr. V. Madsen, at Lifford Road Nurseries, Camberwell, by Protheroe & Morris, at 12.
Imported and Established Orchids in variety, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Variation and Inheritance.

It is singularly appropriate that a son of Charles Darwin should have been selected to preside over the British Association during the year which forms the 50th anniversary of the enunciation of his now famous theory of the origin of species. Mr. Francis Darwin's presidential address will have been read by many, and it provides much food for reflection, and it will certainly serve as a stimulus for the prosecution of further research. And to say this is to admit at once that the whole of the views propounded in that Address are not likely to command, at any rate, the immediate and unreserved assent of many who have busied themselves with the matters therein discussed.

The central idea which runs through the whole Address is that plants share with animals a kind of memory, and it is to the permanence of impressions which have become engraven by repetition upon the organism that not only the habits acquired during individual life are due, but the course of development itself is also shaped by something of the same nature.

Mr. Darwin, in advocating these principles—originally developed largely by Simon—examines the evidence for and against them with an open-minded impartiality that recalls the candour with which the author of *The*

Origin of Species was ever wont to point out the difficulties that seemed to tell against the very explanation that he was himself maintaining.

The "mnemonic" theory which thus formed the principal thesis in the Address, briefly explained amounts to this: We know that animals in general are able to acquire experience, that is, they become more or less consciously aware that certain results will follow certain causes, especially when these affect their own welfare, and thus they do not need, every time a familiar stimulus is applied, to learn the whole lesson again from the beginning. A horse will start at the sound of a whip, without waiting to rediscover by experiment what it has already learned to associate with it. This must mean that some sort of corresponding change has occurred somewhere in the living substance of that horse which is lacking from one that had never undergone the process of being broken in.

Habits, which are obviously related to what we may call memory, offer other examples of the same kind. A man, by practice, may accustom himself to wake at a particular hour, and in time the habit thus formed becomes a part of his life. In respect of this detail, then, we may say that some change occurs regularly and rhythmically and affects his nervous system, without conscious effort on his part, leading him always to wake up at the appointed time.

Now a rhythm of a similar kind is to be observed in plants, and Mr. Darwin has himself contributed much to our knowledge respecting it. Many plants exhibit what are known as "sleep-movements" in their leaves or flowers; that is, the nocturnal position is different from that maintained during the day. Species of Leguminosae—*Phaseolus*, for example—exhibit this character in their foliage. If such a plant be placed in a dark room at night, it will be found to retain the nocturnal attitude of its foliage till next day, when, without the admission of light, its leaves will nevertheless assume the daylight position. At about the time when night comes on the leaves will again fall, just as they would have done in the open air. This affords a wonderful example of what we may call "impressed rhythm" in a movement, and we can alter this and other similar kinds of rhythm experimentally by artificially changing the rate of alternation of the two conditions.

Many additional examples of the same sort of thing could be quoted, and it is plain that plants really do possess the capacity of continuing to react as though a stimulus were applied, even when it is really absent at the time the plant has got "accustomed" to receive it. But memory, if one analyses it, comes to mean that the sensations and often their results may be repeated when the external cause that originally excited them is no longer present. The particular stimulus, which in the first instance started those series of internal changes that culminate in the production of a definite response, ceases to be necessary. The sequence of events is short-circuited, so to speak, and may even be started by causes quite different from that which at first set the train in motion. The net result, however, is the appearance of the

response, though the initial provoking cause is no longer apparent. In this sense, then, we may speak of plants as having memory. We may, however, be permitted to doubt whether our knowledge of the hidden causes of rhythmic movement or other manifestation of change is materially advanced by so doing. For ourselves, we think that the better way still lies in the direction of avoiding physical analogies, and although some distinguished men amongst the biologists have given utterance to their despair of explaining these things in terms of chemistry and physics, we still venture to think that the more fruitful ground lies in this field. Of course we know as yet very little about the chemical and physical state of matter itself—assuming that there is such a thing as matter at all. It is only a few years since we first became aware of the existence of the complexities that are associated with "X" rays, or with the chemical atom, and we are still only beginning to apprehend how intimately chemical and physical change is bound up with the conditions under which the reactions may be proceeding.

If by the mnemonic hypothesis nothing more is meant than that the vital machinery is affected, more or less permanently, by the reactions and changes that are going on within it, we have no objection to offer, although we need not lose sight of the fact that it is just exactly the nature of this affection itself that we want to discover.

When, however, we are also asked to believe that, just as habits may be formed in the individual by the impress of stimuli, so by a similar kind of mechanism these effects may be transmitted to the germ cells of successive generations, we are inclined to pause. The inheritance of acquired characters is a thorny subject, and it has often been discussed in the pages of the *Gardeners' Chronicle*. For the moment it may suffice to say that we regard the case for such inheritance as non-proven. Everyone knows that plenty of instances are repeatedly brought forward, e.g., seeds grown under certain conditions may give rise to plants that are said to thrive best under a similar or definitely related environment, &c., but, so far, such examples, when critically examined, have failed to prove decisive in the affirmative sense.

Again, we find it difficult to regard the steps of development of a plant or an animal, from the egg to the adult, as attributable to the materialisation of echoes of ancestral structures acquired by the progenitors of the race as the result of impressions received from the environment. The secrets of organisation in relation to development are still shrouded in deep obscurity, but perhaps the most outstanding feature that has now become generally recognised is the real, albeit mysterious, nature of that interchange between the various parts of an individual which we designate as Co-ordination. The organism, as a whole, reigns supreme over and above its constituent parts, and not the least marvellous illustration of this is to be seen in the manner in which mutilated bodies, or even detached fragments, may regenerate missing parts, and reproduce the whole irrespective of the morphological nature and past experience of the cells which are

concerned in, or are requisitioned for, the process.

But whatever we may think of the theories and hypotheses that have been advanced to explain variation, and however unsatisfactory we may find them to be, the existence of the thing itself is beyond all dispute. As Charles Darwin recognised fifty years ago, it forms the cardinal point on which the whole possibility of the evolution of new species depends. But given this first step, the further stages in the process are assured by the survival of the fittest for the place and time, and the elimination of the less fitted. In this way the distinctions between the incipiently discontinuous groups become accentuated, and the fact is recognised and expressed in the term "good" species.

Considerable divergence of opinion, of course, exists as to the various steps of the process, and it is likely to continue to do so for a long time to come. But most people will probably continue to regard natural selection as a prime factor in emphasising that process of initial differentiation to which we give the name variation, and such an admission implies that it is, in many cases at least, largely responsible for the gaps which separate the individual species from each other.

OUR SUPPLEMENTARY ILLUSTRATION shows a group of one of the commoner fungi of gardens, *Coprinus micaceus*, growing upon an old oak stump in a garden at Fox Lane, Palmer's Green, London, the residence of Mr. A. E. SMITH, son of Mr. WORTHINGTON G. SMITH. This latter gentleman is well known as a mycologist, and he has furnished us with the following interesting account of the larger species of fungi and Toad Stools that are found in gardens and about dwelling-houses.—*Coprinus micaceus* usually grows in dense clusters upon decaying tree trunks and stumps of all kinds, producing several crops of the spore-bearing organs—the Toad Stools—each year. The photograph from which the picture was prepared was taken in early summer. The fungus is called micaceus because when looked at under a lens it is seen to be covered with minute sparkling grains. By its mycelium, or spawn it gradually and completely destroys decaying wood. Gardeners do not generally approve of fungi in gardens, yet some of the higher types are peculiar to gardens, yards, and other places about dwellings; indeed, some species not only grow in gardens, summer-houses, and close to house doors, but they invade the dwelling-house itself. One known as the "gigantic Mushroom" is called *Psalidota villatica*, because its usual place of growth is near villas or country houses. Sometimes it manages to grow inside sheds and outhouses, and it will even enter the villa itself and luxuriate in the cellar. Only a few days ago some newly-dug earth was wheeled from a kitchen garden to a flower garden at Dunstable, and immediately the earth was laid in a heap, a fine crop of a most beautiful and rare fungus—as if by magic—appeared upon the soil. This was *Volvaria Taylori*, a species that seems to be peculiar to gardens. *Coprinus comatus*, a large and handsome edible species, is almost peculiar to parks, gardens, and yards near houses, for which reason it has been called "the agaric of civilisation." It frequently occurs in the small front gardens of London houses. An allied species named *C. atramentarius* is very common in yards everywhere; sometimes it grows in the streets. On two recent occasions it has pushed

itself up through an asphalt pavement at Dunstable. Another species, *C. domesticus*, grows both outside and inside houses, and will appear with startling suddenness in cupboards, in cellars, sometimes on old floors or hanging inverted from ceilings. It appears to greatly appreciate old matting, dish-cloths, sacking, and discarded carpeting in outhouses and external offices. *C. apothosus* and *C. fuscescens* both grow in cellars and kitchens, often on the structural woodwork in the cellars under ins. *C. radians* grows in the interior of sculleries, where it graces the walls and hangs from the ceilings. *C. flocculosus* and *C. sociatus* are both common in gardens, the latter sometimes decorates garden walls. *C. radiatus* was sometimes noticed on the linen dressings of wounds before the discovery of the anti-septic treatment. No doubt gardens are very suitable places of growth for some of the larger fungi, because manure is often applied, the earth is dug up and is more or less loose, and the beds are kept open and free from weeds. This, however, hardly accounts for the persistent presence of certain fungi close to one's doors, or on the greasy, steamy walls and ceilings of sculleries. Some of these pretty, uninvited visitors are welcome enough, but others are undesirable and not particularly wanted. The malodorous plant named *Thyphallus impudicus* is common in gardens and yards; for some peculiar reason it often grows close to doors and gates, and sometimes even trespasses into the house itself, where it will ensconce itself and luxuriate in a cellar. At times it has been known to insinuate itself between the joints of flooring and develop itself between the rafters, where it soon makes its presence known by a penetrating and truly horrible odour of carrion in a high state of putrescence mixed with coal-gas. It often takes possession of the artistic structures made of old dead branches and stumps mixed with brick-bats in the so-called "rock-work" of town gardens. The "fairly-ryng Champignon" *Marasmius orreades* is very common on lawns, where, in spite of its edible qualities, it is invariably looked upon as an intolerable nuisance. In many gardens *Leptota cristata* is very common; this is a very pretty white fungus with a bright brown middle, and measuring some 2 or 3 inches in diameter. When smelt, it is found to be possessed of a peculiar, pungent, penetrating mephitic-sulphurous odour, a smell which makes human beings shudder and turn cold, yet the smell is of such a nature, as in that of Henbane, that one generally feels bound to return to it. No attempt is made here to enumerate all the fungi peculiar, or partially peculiar, to gardens and houses. Any such list would be a very long one. Two familiar examples may, however, conclude this short note. Everyone has seen or heard of the huge, dusty, black masses of fungus growth so common in old wine cellars, a growth which clothes bottles and bins with a thick sable garment. This is *Zasmidium cellare*. Publicans, by their subtle arts, are able to produce a spurious *Zasmidium* from old, dusty spider-webs, sawdust, and soot. This they cunningly wind around bottles of "British port" as a proof of age and maturity. The other is the one known as "Dry-Rot"—*Merulius lacrymans*; this cosmopolitan fungus introduces itself to the interiors of palaces and cottages all over the world, and it has a way of always keeping carefully indoors. It is called lacrymans, because when detected it is always covered with hypocritical tears, as if pretending to be sorry for what it has done. The fungus itself is a moist or wet one, but it is called "Dry-Rot" because it speedily reduces the woodwork of buildings to dry dust.

ROYAL HORTICULTURAL SOCIETY.—The next meeting will be held at Vincent Square, Westminster, on Tuesday, September 15. At the three o'clock meeting Mr. THOMAS H. MAWSON, Hon. A.R.I.B.A., will give his second lecture on "The Ethics of Garden Making."

THE NATIONAL CHRYSANTHEMUM SOCIETY.

—The exhibitions for 1908 will be held at the Crystal Palace, Sydenham, on Wednesday and Thursday, October 7 and 8; on Wednesday, Thursday, and Friday, November 4, 5, and 6; and on Wednesday and Thursday, December 2 and 3. The Society is making slow but steady progress. During 1907 77 new members (12 Fellows and 65 ordinary members) were added to the roll, as compared with 60 in the previous year. The Floral Committee awarded 44 certificates to novelties, but these were not all granted at the exhibitions, as the Floral Committee meets frequently during the winter months for the purpose of examining plants, cut flowers, &c., submitted for awards. The secretary is Mr. RICHARD A. WITTY, St. James's Villa, Swains Lane, Highbury, N.

HORTICULTURAL TRADES ASSOCIATION.

—This Society has just completed its annual congress, the meeting taking place this year in London. The gathering was a record one as regards numbers, over 100 leading members of the nursery and seed trades attending from all parts of the United Kingdom. The three days allotted were devoted to excursions around London, the evenings being devoted to business meetings for the discussion of topics of trade interest. Among the nurseries visited were those of Messrs. HUGH LOW & CO., Enfield; PAUL & SON, Cheshunt; W. PAUL & SON, Waltham Cross; THOS. ROCHFORD & SON, LTD., Turnford; and JAS. VEITCH & SON, LTD., Coombe Wood. Unfortunately the weather on the last day was wet and cold.

THE FRENCH NATIONAL CHRYSANTHEMUM SOCIETY.

—This Society, founded in 1895, has made remarkable progress, and has just succeeded in enrolling its 800th member (inclusive of 59 affiliated Societies). The executive are hopeful that in the near future they may be able to make the membership list up to 1,000.

THE PRESERVATION OF FRUIT IN COLD STORAGE.

—The process of preserving fruits by the artificial application of cold temperatures is making progress. There was shown at Lyons recently a collection of dessert Pears, which had been gathered seven months previously. The degree of preservation of the fruits was complete from every point of view, and no shrivelling was observed. The artificially-produced cold had hindered change in the flesh entirely, paralysed the activity of fungal organisms, and killed all insects that were present. In contradiction of the common belief, the fruits kept better than those freshly gathered when exposed to the air, and they bore long transit better. In opposition to these favourable experiences of the French and United States growers, the Dutch garden Press asserts that the cold storage treatment has a bad effect on flavour, as compared with the ordinary storage.

THE SEEDING OF CARNATIONS.

—In an interesting article by M. GRIGNAX, which appeared recently in the *Revue Horticole*, an account is given of the yield of seed in Carnations grown under glass. The observations were made on plants cultivated in America, where there is a considerable trade in the winter-flowering sorts. On the whole, the results were what might have been expected. The largest yield and the best quality, both as regards weight and germinative capacity, were obtained from the plants which had been pollinated early. Thus there was a steady falling off from October to February in the results of artificial pollination. No doubt this is due to several factors, the earlier flowers furnish more (and perhaps better) pollen, whilst the plants have not been weakened by the previous production of blossoms. Possibly, also, the time of year itself may exert some influence, inasmuch as the physiological conditions connected with illumination continue to change as the winter advances.

MECONOPSIS SINUATA.

DURING the past few years several welcome additions have been made to the number of cultivated species of this attractive genus. Perhaps the most popular and well-known among these is the handsome Tibetan *M. integrifolia*, with its large and beautiful yellow flowers, borne erect on stout stems. Of quite another character, but possessing a grace of its own, is the red-flowered *M. punicea* from the same region, with its drooping flowers consisting of three large petals. From the Eastern Himalaya and Tibet we have *M. racemosa*, with entire leaves and stems covered with stiff hairs, and racemes of purplish-blue flowers of a semi-double character. A charming little plant is *M. bella*, from the Eastern Himalaya, with *Corydalis*-like leaves, and light blue flowers on stems only 2 or 3 inches high. This species, which grows at a very high elevation, has, so far, proved difficult of cultivation, except in certain localities. It is, however, one of the few perennial species. *M. simplicifolia* resembles *M. punicea* in habit, but has smaller violet-blue flowers, on shorter stems. It is a native of the Central Himalaya. *M. grandis*, from the Eastern Himalaya, with coarsely-toothed leaves and the habit of *M. integrifolia*, has proved of more perennial duration than the others, with the exception of *M. bella*. It bears good-sized, purplish-blue flowers. *M. Henrichii*, with flowers of the same colour, comes from Western China, and was introduced with *M. integrifolia*. The latest addition is *M. sinuata*, illustrated at fig. 88. Seeds of this species were received from Kashmir in the spring of 1906, having been sent home by Lieut.-Colonel Appleton, R.E. The typical plant has been supposed to be confined to the Eastern Himalaya, but that it has a wider distribution is proved by the seeds having been collected so much further west. Plants flowered at the Royal Botanic Gardens, Kew, and in the nurseries of Messrs. Jas. Veitch & Son this summer, and Messrs. Veitch exhibited plants of the species at one of the meetings of the Royal Horticultural Society under the name of *M. aculeata*, a plant which it much resembles in general character. In the latter species, however, the foliage is thinner and more deeply lobed. *M. sinuata* has larger leaves, with sinuate margins, and these, as well as the 2 feet high stems, are covered with stiff hairs. The flowers are of a pale purplish-blue colour, while many of the petals have a distinct cusp at the apex; the ripe seed capsules are longer and narrower than in *M. aculeata*. With the exception of one plant, all those that bloomed this year had single flowers, the one exception being that shown in the present figure, which developed flowers of the semi-double character of *M. racemosa*. Both *M. aculeata* and *M. sinuata* take two and sometimes three years from seed to produce flowering plants, which usually die after ripening seed. They both succeed under conditions usually afforded other members of this family, namely, shade and moisture, planted in a mixture of loam, peat, leaf-soil, and sand. The rough drainage is essential, as the roots are very liable to rot during our winters. W. Z.

THE FRENCH CULTIVATION OF MUSHROOM SPAWN.

ONE of the chief industries in the French gardens during the winter months is the making of Mushroom spawn. The Mushroom growers generally buy their spawn from the "maraichers," as the French market-gardeners are termed, who always have on their premises a cellar built for the purpose of cultivating the fungus. The maraichers have at this time of the year some manure ready to be brought into the cellar. This manure is from well-fed horses, and it is turned over at least three times; each time the outside portion of the heap is placed in the centre. The manure is watered if too dry; but if the weather

is wet some dry straw is spread over the heap. When it is well broken up and most of the ammonia has become dissipated, the manure is brought into the cellar to be made up into ridges 16 inches wide and 16 inches high. This is entirely done by hand, placing it in layers 2 or 3 inches thick and well pressing it down with the knees and closed fists as the work proceeds. The bed, when made, is trimmed and the surface made as smooth as possible.

When the heat of the manure does not exceed 65° F., the spawn, which has been previously started in a damp place for a few days, is inserted. Small pinches are set every 3 or 4 inches

spawn is then sorted out, all bad parts being rejected. The fungus is considered to be at its best condition when it shows a bluish colour.

What is not sold is set in thin layers in a shed to dry, and when it is dry it is sold by weight, or the maraichers cover the bed with a layer one-third of an inch in thickness of fine new soil that has been well mixed, when possible, with one-third of sifted old mortar. The virgin spawn is, in the first instance, collected by workmen, who find it on refuse heaps, or against old walls, and sometimes in the open ground. They sell it to the maraichers, who dry it under cover till they are ready to plant it. They allow it to grow in the beds until the first Mushroom appears, when they judge of the quality by the colour, which varies from pure white to grey. The best type of Mushroom has a thick, sturdy stalk, supporting a cap of good size. If the strain has commercial value, the spawn is lifted and dried at once, or set to increase in another bed. It is sold to the Mushroom grower, and this second spawn is called the "Frank spawn."

By saving part of the mycelium brought by the collector and part of the spawn grown direct from the "virgin spawn," the maraichers can grow a good strain for a period of 18 months, after which it always loses some of its vitality. Out of 20 virgin spawns obtained from the collector, sometimes as many as 15 are thrown away as unsuitable. The Mushroom growers store the spawn in a special room, and it is labelled with particulars as to its origin, the date when it was grown, and by whom. *P. Aquatin, Maryland, Essex. August 28, 1908.*

LILY CULTURE IN SOUTH-WESTERN SCOTLAND.

SIR HERBERT MAXWELL, Bart., who is a great cultivator of Oriental and Occidental Lilies, writes to me as follows in a recent communication:—"Lilium monadelphum var. Szovitzianum is a fine plant, and one of the good-natured Lilies. I have grown it at Monreith for 30 years; but you beat me by 3 feet. The other species which succeed best with me are *Lilium pomponium verum* (scarlet), *Lilium pardalinum*, the highly distinctive Panther Lily of California, *Lilium canadense*, and *Lilium Martagon*, *dalmaticum*, and *album*." He also adds, regarding a somewhat miniature Japanese Lily of comparatively recent introduction:—"Lilium rubellum, of which I hoped great things, has succumbed after two years of vigour." My own experience of this unreliable Lily is almost precisely identical with that of Sir Herbert, but with me it only flowered for one short season, and then entirely disappeared. Its bulbs, as I have indicated, are insignificant in dimensions, and only too attractive for the anatomical studies of insect life. It is also very susceptible, like many other Lilies, to the varying influences of the atmosphere and the conditions of the soil. This susceptibility is almost equally characteristic of another and even more exquisite Lily, viz., *Lilium Kramerii*, also a native of Japan. It was discovered in the year 1872 by M. Carl Kramer, growing wild among the Japanese mountains of Senano in the island of Nippon, likewise in other regions at an elevation of nearly 4,000 feet. It was introduced into this country at the request of the naturalist whose name it bears by the late Dr. Wallace, of Colchester. *Lilium Kramerii* is undoubtedly one of the loveliest of all the floral treasures that have come to us from Japan. It is very unfortunate, therefore, that, like *Lilium rubellum*, it almost requires to be planted every year, in certain soils at least, that are too cold, wet, and adhesive for its well-doing. I have to

Photograph by W. Irvine.

FIG. 88.—MECONOPSIS SINUATA: FLOWERS PALE PURPLISH-BLUE.

each way. The spawn is not in brick form, but the fungal threads only are used; it is known as "virgin" spawn. Sufficient moisture is afforded by wetting the paths and the walls only. If the heat is too high when the spawn has been set, some apertures are made in the bed at intervals by a stick. It takes about six weeks for the spawn to spread all through the mass, and its growth can easily be known by the shrinking of the bed. The spawn is generally sold to three or four Mushroom growers, who come on an appointed day. The bed is then cut with a special saw into portions each 1 foot in length, the

lament the loss of my plants of *Lilium auratum* this season through rabbits. This, however, might have been prevented by close wire netting, which is, I find, an adequate protection. Of my other Lilies that did not suffer from such unexpected invasions, the finest have been *L. szovizianum*, already characterised, *L. chalcedonicum*, the beautiful Scarlet Martagon, which has bloomed in the same position for the last 20 years, and *Lilium pardalinum*, with its richly-coloured and profusely-flowering derivative, *Lilium Burbankii*. The flowering season of *Lilium speciosum* has not yet come. *David R. Williamson*.

THE AMERICAN GOOSEBERRY-MILDEW ATTACKING RED AND BLACK CURRANTS.

LAST season I announced, in the *Gardeners' Chronicle*, July 13, 1907, p. 26, the first occurrence in England of the American Gooseberry-mildew (*Sphaerotheca mors-uvale*, Schwein., Berk.) on the Red Currant. It occurred in a plantation in Norfolk, and the variety attacked was the "Grape." This summer I have observed the American Gooseberry-mildew on Red Currants in plantations near Swanley, Rochester and Sittingbourne, in Kent. The varieties which have been attacked are Victoria, Raby Castle, and Long Bunch. In one plantation rows of the two varieties Raby Castle and Victoria adjoined Gooseberry bushes virulently attacked by the mildew, and so far as could be seen the mildew had attacked only the Victoria bushes, and completely passed over the Raby Castle (a variety which in other plantations has been attacked). In this particular case, too, there were indications that the mildew had only just passed on to the Red Currants from the diseased Gooseberries. It appeared that the mildew had not yet perfectly adapted its parasitism to the new host-species, since it was not uncommon to find small patches here and there on the Red Currant leaves, which were brown and dead as the result, apparently, of the too fierce attack of the mildew. A similar phenomenon has been observed in the case of rusts when they pass on to a new host-species to which their parasitism is not perfectly adapted.

A very important feature of this attack of Red Currants by the mildew—and one which is very disturbing from the economic standpoint—is the fact that on this host-plant the mildew forms the brown, felted mycelial patches, containing the *perithecia* and winter-spores, on the under surface of the leaves as well as on the young wood. In the case of the Gooseberry—so far as I have seen in England—the winter stage is produced in the young wood and berries only, and never on the leaves. Consequently there is the possibility—remote though it is—that the disease can be entirely removed from affected Gooseberry bushes by severe pruning in the winter, the measure now being ordered in the Board of Agriculture's "Gooseberry-mildew Orders" in a number of counties. The occurrence of the winter stage on the leaves of Red Currants means that—as in the case of the Hop-mildew—the *perithecia* will fall to the ground and thence re-infect the plant in the spring, despite any pruning of the bush, in the case of the Red Currant. It is one further proof of the utter futility of the measures at present being taken by the Board of Agriculture against this mildew, and should convince them that only the total destruction of diseased bushes is the scientific and economic method.

Further, I have seen, during this summer, the American Gooseberry-mildew on the Black Currant. The specimens were collected by Mr. K. G. Furlay, one of the inspectors recently appointed from Wye College by the Kent County

Council, and were obtained near Rochester. The variety was "French Black." The mildew was in the summer (conidial) stage only, and the attack was very slight. I learn from the Board of Agriculture that one of their inspectors has met with a similar case in Huntingdonshire. *E. S. Salmon, F.L.S., Mycologist to the S.E. Agric. College, Wye, nr. Ashford, Kent.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

FLORICULTURAL HISTORY.—I have read with much interest *J. D.'s* review of Mr. Howard Crane's new book on the Pansy, Viola, and Violet. Like many other of our recent writers on florists' flowers, Mr. Crane does not seem to have given much attention to the subject of the history or the literature of the flower with which he deals. Literary and historical research in floriculture nowadays appears to be at a somewhat low ebb, for many of our modern authors simply repeat what has been said before by others, often with the same errors, and original research is practically ignored. Yet this need not be. As *J. D.* points out, the Pansy, or Heartsease, was known and grown long before Thompson, or Thomson, of Iver, came on the scene. But if our author had desired to show us some of the improvements that have taken place in the flower, he could, as *J. D.* says, have easily referred to the *Floricultural Cabinet*, where many illustrations of old-time Pansies are to be found. There are also many illustrations of these early seedlings in other floricultural works, not the least interesting of which are those in the *Horticultural Journal or Florist's Register*, about 1833-7, which are executed in far better style than are those of the *Floricultural Cabinet*. Another work giving good examples of the progress of the Pansy in those days is the *Floricultural Magazine*, sometimes bound up and labelled as the *Florist's Museum*. By far the best treatise on the history and culture of the Pansy is that by Singer & Freeman, published in 1835 and containing 24 coloured figures of Pansies then grown. Many of these were Thompson's seedlings, and although I make no claim to be considered a Pansy specialist, yet it is open to question whether some of these flowers were very much inferior to those grown to-day. It is not so long ago since I had occasion elsewhere to draw attention to the opening statement of a recent author on the Dahlia, who deplored the fact that material for his history was not so plentiful as could be wished. That depends on whether one knows where to find it, and I do not hesitate to say that there is as much literary and historical matter available for writing a history of the Dahlia as one could possibly desire. So, too, with the Pansy, but our modern authors either have no time or no inclination for the task of original research, and so time after time we get the same story, the last author often repeating the errors and misprints of the previous one. It may be that Americans are altogether to blame. When an author interests himself in the culture of a flower he may not perhaps feel bound to collect all the literature on the subject. The next best thing is to let it severely alone unless he can gain access to a good library where the material can be found. And here English horticulturists are at a great disadvantage. We have no great horticultural library where we can go for the purpose of original research in matters relating to our favourite flowers. There is practically little or nothing at the British Museum, the Lindley Library, whatever it may be as a scientific, botanical library, augmented by some modern books on gardening, is absolutely useless to the student of floricultural literature. Its catalogue, published ten years ago, is a mere list of authors, and there is no subject index to it, and if there were, what should we find in the way of rare old literary or historical works relating to any of our flowers, such as the American, Hyacinth, Tulip, Carnation, Marigold, pansy, anemone, Dahlia, Pansy, Pelargonium, and others? Hence the present-day author, unless

he had—his own floricultural library, must find what historical and literary matter he wants elsewhere. I observe in the R.H.S. book of arrangements that the Lindley Library is described as a "magnificent and unique collection of horticultural books," and that it consists of 6,000 volumes. I wonder whether the person responsible for this somewhat extravagant language is aware that the library of the Masses, Chiswick, Horticultural Society consists of 17,000 volumes, and that the library of the National Horticultural Society of France has over 15,000, and why a collection of 6,000 is to be considered "unique" when it certainly does not contain many of the rare old works on gardening that the two other libraries do? I have had practical proof on more than one occasion that this "magnificent and unique collection" is of no use to the average literary worker in horticulture, because it does not contain what is wanted and what might reasonably be expected to be found in a horticultural library. It may be that in other departments, such as fruit and vegetable culture, many important works are missing from the Lindley Library. With that I am not concerned beyond having tested its catalogue for the Strawberry. The result is the same as for horticulture, absolutely nothing of any account is to be found relating to the Strawberry. It seems to me that what is wanted is an up-to-date supplement, so that literary workers may know what the library does contain. Another thing to be considered is the appointment of a librarian who has some knowledge of horticultural literature, and who could help to build up a library that would be of service to horticulturists of all sections. The R.H.S. is in a prosperous condition, and money spent in making a library of its own or in continuing the Lindley Library would be well laid out. The rare old gardening books obtainable to-day cost infinitely more money than they did twenty years ago. In twenty years' time they may be unobtainable altogether, for collectors are numerous and prices are rapidly rising. *C. Harman Payne, tnt, Wellmeadow Road, Catford, S.E.*

THE WISLEY COLLECTION OF GRAPES.

When the Royal Horticultural Society transferred its gardens from Chiswick to Wisley cuttings of the vines from the great vineyard and other houses at Chiswick were secured. Many of the varieties have become scarce in commerce, and thus it is that there is now at Wisley in good form a magnificent collection of Grapes. It is pretty generally known that it is the intention of the Council to have bunches of these Grape varieties exhibited at a meeting of the Society towards the end of the present month, but those who are specially interested in Grapes, and in the characters of the vines producing them should endeavour at once to see the collection as it now is, as the various characters and growth of each one can be studied with great advantage. The vineyard is a span-roofed structure of average height, 100 feet in length by 30 feet in width. The vines comprise 40 varieties, but only 38 are fruiting, two of the original planting having proved to be wrongly named, and have been replaced by young vines. There are 20 plants on each side of the house, and they are about 5 feet apart, and are trained on single rods. They were planted in the spring of 1905. The border is inside, and is at present 4 feet wide by about 3 feet in depth, and is mainly composed of old pasture turves laid one on the other, grass side downwards. The growth of the vines has from the first been vigorous; indeed, last year's rods were so stout that experienced vine growers feared this year a bad break in consequence. Happily, so far from that being the case, the eyes broke splendidly, developing about six or seven good buds on each of them, each from six or seven good bunches of Grapes. There are equal numbers of white, and black or coloured varieties. Although the house is in three compartments, no difference seems to have been made in the heat applied, for all have been planted indiscriminately and treated alike. The black or coloured Grapes are: Gros Colmar, Gros Maroc, Black Alicante, Lady Downes, Diamond Jubilee, the poorest cropper of all; West St. Peter's, Black Prince, Director, L'Esperand, L'Esperand, Black Monique, Godeuse, Apple Towers, Barbarossa, Alwick Seedling, Muscat Champion, Muscat Hamburg, Black Hamburg,

Grizzly Frontignan, Madresfield Court, and Prince of Wales. This last-named Grape is, as seen at Wisley, the handsomest and best fruited of the whole collection. The remaining coloured variety is Mrs. Pince's Black Muscat, which will doubtless fruit well also in due course. The white or yellow Grapes are Mrs. Pearson, Lady Hutt, White Tokay, Trebbiano, White Nax, Foster's Seedling, Chasselas Napoleon, Muscat of Alexandria, Hungarian Muscat, Bowood Muscat, Canon Hall Muscat, Golden Queen, Golden Champion, Duke of Buccleugh, Duchess of Buccleugh, Ascot Citronelle, Diamant Traube, White Frontignan, and Syrian. A. D.

FLOWERS OF SPENSER.—With regard to Mr. Englehart's interesting note on p. 172 concerning the derivation of Walnut, it may be noted that Walnuts are called Welshnuts by the natives of Dorsetshire and parts of Somerset. (See Bates's poem, "The Welshnut Tree.") Without pretending to know whether Walnut is more probably derived from Welshnut or Avelanant, may I point out that the rejection of the Welshnut theory calls for some other explanation of the Dorsetshire provincialism, such words being usually based on some well-founded origin. *Herold Evans, Llanishon, Cardiff.*

THE FORMATION OF DEW.—Reading carefully your very interesting leader of the 28th ult., on "Nectaries and their Origin," written, too, in simple unscientific phraseology, I was a little startled to find that in the fifth paragraph a theory was expounded in relation to the formation of dew which seems to be distinctly the converse of that usually held. Thus in a scientific book I read, "Dew is moisture of the atmosphere deposited on a cool surface, another form of condensation, in fact." Those few words seem to convey the general belief or theory held regarding the formation of dew, that it is the moisture abstracted from the earth and vegetation by warmth during the day, and passing into the air in the form of vapour, which, chilled or condensed by the colder air of the evening, falls or is deposited on the earth's surface and vegetation as moisture. In the paragraph of the leader referred to it is presumably laid down that dew is excessive moisture, forced into vegetable leafage by root action, which, on the withdrawal of the day warmth, such as hitherto has created from it vapour, now suffices leafage with water, and thus becomes dew. That theory, as to the correctness of which I would not at this moment prefer to question, does seem to place the subject of dew formation in a new light, and one may well desire a matter of so much interest to the student should have the clearest elucidation. I presume the moisture which in winter, and when the air is heavily charged with vapour, settles on all vegetation, even leafless trees, and becomes dense hoar-frost is not produced according to the new theory. More light on the subject would be most acceptable. D.

While in no way questioning the accuracy of the description given in your interesting article on p. 166 of the methods employed by plants to dispose of their superfluous moisture, I cannot help feeling that the writer of that article is at fault when he says that dew on grass is a result of these methods. Surely dew, or by far the greater portion of it, is not exuded by plants, but is deposited, especially on cold surfaces, from the air, which must give up some of its water-vapour as it becomes cooler at night. Thus we get the heaviest dews at seasons when there is the greatest difference between the day and night temperatures. Garments and other objects from which no exudation of moisture can take place become wringing wet with dew. Incidentally this theory of dew as condensed water-vapour has been advanced as the explanation of the Dew Pond, "ruined that never fails," that is so valuable to the farmer on the dry Sussex Downs, an explanation which, though not thoroughly proved and accepted, is, perhaps, the most feasible that has been put forward. *Herold Evans, Llanishon, Cardiff.*

It is certainly quite true that dew, i.e., drops of moisture, may be, and often is, formed as the result of condensation of aqueous vapour from the atmosphere in consequence of the chilling of the warm, vapour-laden air. The formation

of clouds and mist are familiar examples of such condensation, and the wetting of clothes or the deposition of hoar-frost referred to by our correspondents, afford other and apt illustrations of the same phenomenon. But it is equally true that much of what passes for dew does not originate in this manner, although *D.* is quite correct in saying that references in literature are commonly restricted to the former, more purely physical, method of its deposition. But under the conditions specified in our article, the almost sudden appearance of copious "dew" is not satisfactorily explained in this way, and, furthermore, the drops of water may, with care, be observed to exude from a region situated just behind the apex of the grass leaf. It is also a fact, familiar to those who have paid special attention to these matters, that certain plants more readily exhibit dew-drops than others. These plants are found to possess the water-excreting organs referred to in our article, and their effluency in conjunction with the excretion of dew-drops can be easily demonstrated by forcing water into the stems under suitable pressure, thus imitating the root action. Many people have also doubtless observed the drops of water that habitually form, by exudation, on leaves of grass that may happen to be growing under a bell-glass when the soil is warm. Here also the root absorption drives more water into the plant than can be eliminated by ordinary transpiration or evaporation in the close atmosphere of the bell-jar. It was not, of course, intended that an impression should be conveyed by our article that we denied the fact of the condensation of aqueous vapour from the atmosphere, but rather to make it clear that much of the so-called dew, which is commonly attributed to this source, in reality owes its origin to a very different set of conditions.—E. J.

GRAFTING THE DOUBLE-FLOWERED GYPSOPHILA PANICULATA.—Attention is directed at p. 133 to the grafting of this plant on pieces of roots of the typical species, and the fact is of interest so far as it goes. Unfortunately, species of *Gypsophila* grow rather freely from root cuttings, hence the possibility, or indeed the probability, of the root pieces being themselves forced into growth by being subjected to the temperature of 60° or 65° Fahr. These suckers may not be of a size sufficient to attract attention when the plants are bedded out, but a very considerable proportion may make further growth later on and prove not a little perplexing to the gardener. To-day the causes of sports, reversions, and mutations in plant life are subjects of frequent comment, and if the grafting of this plant is carried out to any considerable extent these single-flowering shoots may be mistaken by the gardener as another instance of the inconsistency of double-flowered plants. *E. H. J. York.*

FEMALE FLOWERS ON BEGONIA GLOIRE DE LORRAINE.—On practically every raceme of *Gloire de Lorraine* bloom the last flower produced is a female one. By the time this flower makes its appearance, however, the plant has lost most of its beauty, and the inflorescence is removed before the female flowers open. It follows, therefore, that, to produce seeds of this plant, the inflorescences should not be pulled off until every flower has opened. *C. H. Maden, Ton.*

HIBISCUS SYRIACUS.—In his timely note about this beautiful shrub, *H.* lends himself to the usual misconception of British climate, namely, that its winter severity varies from north to south, instead of from east to west. He describes *Hibiscus syriacus* as being "only hardy in the southern parts of these islands." In fact, it is perfectly hardy all along the west coast as far as Ross-shire; but, being a late bloomer, northern summers do not afford it enough sunshine to produce its flowers before the autumn frosts, unless the plant is trained against a brick wall. So treated, it flowers freely. It is one of the very best shrubs for planting in London, where it enjoys the sun-beat, redoubled by reflection from pavements and buildings, and is indifferent to drought and heat. There is a splendid specimen of the kind, with single white flowers blotched with claret, in the forecourt of one of the old houses in Cheyne Walk, Chelsea. Many a time have I refreshed my eyes with its profuse blossoms when the House of Commons has sat late into August. *Herbert Maxwell, Monmouth.*

MUTISIA DECURRENS.—I enclose two photographs (not reproduced) of the climbing Composite *Mutisia decurrens*, growing in the garden of Dr. Dukinfield W. Scott, at Oakley, Hants. The plant has successfully weathered last winter in the open. It is planted against a south-east wall, and is in full flower at the present time, making a lovely show, with its handsome orange flowers that measure 5½ inches across. Each leaf ends in a tendril, which attaches itself to the rough surface of the wall. *Rina Scott.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

SEPTEMBER 1.—*Present:* Mr. Chas. T. Drury, F.L.S., V.M.H. (in the chair); with Messrs. Jas. Douglas, J. W. Odell, W. Fawcett, J. Fraser, H. T. Gussow, Geo. Gordon, and J. T. Bennett-Poe.

Mildew on Oak leaves.—Mr. Gussow reported that the fungus on certain Oak leaves sent for inspection is probably a form of the same; that it is in its conical stage *Erysiphe coccinea*.

Gall on wild Rose.—Mr. DOUGLAS showed specimens of the Rose gall, *Coelomyia rosarium*.

Stylocarpus.—Mr. J. W. ODELL showed *Stylocarpus* having (a) in a light-flowered variety a regular peduncle with six segments, the whole flower being campanulate; and (b) in a dark-flowered variety the peduncle branched and the bracts foliaceous instead of very small, as is normal.

Abnormal flowering of Laburnum.—Mr. GEORGE GORDON mentioned that at the present time a *Laburnum* was flowering freely in his garden at Kew. The tree had occupied its present position some 15 or 16 years, and, owing to it occupying too much space, the whole of the branches were cut back to within 3 or 4 inches of the main stem. The tree produced new shoots from the stumps of the branches, and of these about two-thirds produced terminal racemes of flowers, which were of a much larger size than the racemes previously produced.

Victoria Plum.—Mr. C. T. DRURY showed a *Victoria Plum* upon which was a group of insect eggs on a stalk, which had at first slight appearance of a fungus, but it was determined to be something like the stalk and eggs of the lacewing fly, than which they were, however, somewhat smaller.

Tomato with enlarged calyx.—Mr. F. FELLOWS WILSON, of Alveston, Chobham, Surrey, sent a Tomato with an extraordinarily large calyx, the segments measuring about 3 inches in length. It is not uncommon for the calyx to extend to this extent, particularly if the Tomato plants are allowed to bear but few fruits on one branch.

Discoid Apples.—Mr. J. G. HOWLETT, of 36, Broadale, Norwich, submitted some Green Beaufin Apples which were diseased. Mr. Gussow undertook to investigate the matter.

New Night.—A few diseased sprigs of *New* were submitted from Mrs. F. LYELL, of Ruckmans, Oakwood Hill, Surrey; the matter was left with Mr. Gussow to report.

Daffodil poisoning.—Dr. C. B. PLOWRIGHT sent the following interesting note: "Cases in which the handling of *Daffodil* flowers by the gatherers has caused poisoning is one often heard of, but how many are really due to the flowers themselves and how many to incipient eczema or other skin diseases on the part of the gatherer is not so clear. Cases in which the bulbs themselves are mistaken for as food are not nearly so frequent. The following note may, therefore, be of interest. A gentleman in King's Lynn purchased in the month of December, 1904, a number of bulbs. These were, for security, placed in a paper bag upon a shelf in the kitchen. By some mischance the *Daffodil* bulbs became mixed with the household stock of Onions, and eventually were sliced up together with them and used in the preparation of soup, which was partaken of by the whole family. Shortly after the meal all the members were sick, they vomited freely, and suffered more or less from nausea, but they had neither

abdominal pain nor diarrhoea. Recovery took place in from six to eight hours. The actual number of Daffodil bulbs used could not be ascertained. The remainder of the soup was used on the following day with the same result. This led to the investigation of the Onion soup. That the illness was not due to ptomaine poisoning is shown by the complete recovery in eight hours, and by the absence of pain and diarrhoea."

Alion plants, &c.—Mr. J. FRASER, F.L.S., showed a specimen of *Erysimum altissimum* L., a plant previously recorded as occurring spontaneously in Britain in the *Journal of Bot.*, vol. x., under the name of *Erysimum panicum*, and in the *Flora of Sarkey* (1838) as being found as an introduced plant at Battersea Fields. Mr. FRASER had himself found it at East Ham in 1906, at Greycoat Place, Westminster, 1907, on Putney Common, and on the new Kingsway and Aldwych sites this year. The specimen he showed had its petals reduced to the claw, as if resorting to self-fertilisation. In addition to this plant he had found upon the Kingsway and Aldwych sites the following British plants: *Epilobium angustifolium*, *E. hirsutum*, *Senecio viscosus*, *Pyrus Malus*, *Brassica Rapa*, *Cnicus arvensis*, *C. lanceolatus*, *Sonchus arvensis*, *Pteris Aquilina*, and *Centaurea cyanus*; and the following aliens: *Erysimum altissimum*, *Salvia verticillata*, *Eriogon canadensis*, *Fragaria chionocens*, *Eschscholtzia californica*, *Cucurbita Pepo*, *Helianthus annuus*, *Oenothera biennis*, and *Papaver somniferum*.

VEGETABLE TRIALS AT WISLEY.

AUGUST 25.—A meeting of the Fruit and Vegetable Committee was held at Wisley on this date to examine the various vegetables under trial. Present: G. Bunyard, Esq. (in the chair), and Messrs. O. Thomas, G. Woodward, W. Bates, G. Reynolds, J. Davis, H. Markham, C. Foster, J. Willard, and A. Dean. The first inspected was a breadth of Cabbages from a sowing made on March 21. There were more than 90 stocks under trial, but many of them, however, were of the coarse Drumhead or Cattle Cabbage type. Ultimately it was agreed to make selections of the varieties under their respective types.

Early White Heart type.—The following, irrespective of any previous awards, were granted Awards of Merit:—*Express* (Vilmorin); Best of All (Barr & Sons); Sutton's Earliest (Sutton & Sons); Paris Market (Vilmorin); Paris Market (Barr & Sons); and Earliest of All (Jas. Veitch & Sons).

Sugar Leaf type.—*Les Etampes* (Vilmorin); *Les Etampes* (Heinemann); All Heart (Sutton & Sons).

Enfield Market or larger type.—Autumn Exhibition (Barr & Sons); Myatt's Early Eveham (Nutting); and Incomparable (Jas. Veitch & Sons).

Offenham type.—Improved Nonpariel (Nutting); Improved Nonpariel (Sutton & Sons); Small Nonpariel (Jas. Veitch & Sons); First Crop (Johnson); Wheeler's Imperial (Sharp); Market Garden (Veitch & Sons); Little Gem (Sutton & Sons).

Red Cabbages.—Dark Red Erfurt and Miniature Red (Barr & Sons).

The large and successful trial of Parsleys was again inspected. There were two rows of each stock, and the plants had made full growth. These were put into divisions as follows:—

Dwarf compact Curled.—Massey's Dwarf Perfection.

Fern-leaved.—Sutton's Garnishing (Sutton & Sons) and Johnson's Perfection (Johnson).

Strong-growing Curled.—Beauty of the Parterre (Carter & Co.); Emerald Green (Carter & Co.); Extra Double Curled (Carter & Co.); Hunt's Extra Fine (Barr & Sons); Moss Curled (Nutting).

An outdoor trial of Tomatos, each variety represented by some 50 to 60 plants, showed that the best cropping and by far the earliest-ripening variety was *Lyc's Early Prolific* (Wadds), and it received an Award of Merit.

The Parsleys are to be tested for hardiness during the winter. A sowing of Cabbage seed for autumn planting has been made. Late Cabbages have yet to be inspected, also late Potatoes, and a large trial for tap-rooted Beets.

SEPTEMBER 4.—An inspection of a trial of Dahlias grown at Wisley was conducted by joint sub-committees of the Floral Committee and of the National Dahlia Society on this date.

The torrential rains experienced immediately before the inspection had by no means improved the flowers, and the dull weather generally of the past fortnight has been unfavourable to the plants. The committee considered freedom of flowering, colouring, and value of the plant from the garden standpoint. The following varieties were adjudged worthy of three marks:—

Dahlia Emily Hubbard.—The plant is very free in flowering, and the white flowers are borne on erect stems. It belongs to the decorative type, and the shoots attain to a height of 4½ feet.

Dahlia Brightness.—A rather large-flowered variety of the Pompon class of type. The colour is scarlet, the growth and flowers alike being erect. The plant reaches 3 feet in height.

Dahlia Avoca.—A free-flowering Cactus form, of crimson-scarlet colour, the florets being tipped with reddish-pink. Height, 4½ feet.

Dahlia Miss Willmott.—A free-flowering variety growing 4½ feet high. The flowers are of medium size, coloured yellow, with orange shading, and are produced with freedom.

Dahlia Stuart.—The flowers of this fine Cactus variety are rich bright crimson with maroon centre. The height is 3½ feet.

The Floral Committee also examined the trial of *Phlox decussata*, and each of the following varieties also received three marks:—

Phlox Prosper Houry.—The plant is of dwarf growth, being not more than 18 inches high, but it is remarkable for its free-branching habit. The flowers are large, and almost circular in outline. The petals are pure white, with a conspicuous lilac centre.

Phlox Comtesse de Jarnac.—A variety with leaf variegation of white, cream, and green. This variety was not in flower, the leaf character alone being considered.

The Committee granted the three-mark distinction to:—

Zea japonica gigantea quadricolor.—A beautiful and striking variety of Maize, in which the colour shades are disposed in longitudinal stripes.

AWARD OF MERIT.

Rose Mrs. Littleton Dewhurst.—A white-flowered sport from the well-known Lady Gay variety, the pink-touched buds contrasting well with the purity of the abundantly-produced blossoms. This variety obtained an Award of Merit on September 1, but was omitted from the official list of awards. Shown by Messrs. J. R. FEARSON & SONS, Loddham, Notts.

SCOTTISH HORTICULTURAL.

SEPTEMBER 1.—The monthly meeting of the above association was held at 5, St. Andrew Square, Edinburgh, on the above date. Mr. Comfort, of the City of Edinburgh, occupied the chair, and there was a moderate attendance of the members. A paper on "The Pleasures and Penalties of Vegetable Judging, with Suggestions as to Improved Methods of Staging," written by Mr. Thomas Fender, Cultuographer, was read by the secretary. Mr. Fender said, with the exception of Leeks, the best vegetables were always to be found in the "collections," and the way in which these collections were set up amply justified the title "display" which was applied to them in the prize lists of some societies. Cabbages, Savoy, Greenkale, &c., were often placed on the tables without any attempt being made to make them an attractive feature of the show. He had tried light, wooden frames for exhibiting such vegetables as Cabbage, Savoy, Cauliflowers, &c., but he thought, where space was available, that banks or mounds of sand, into which the stalks of vegetables could be stuck, answers well. Such vegetables as Leeks and Celery could not be set up in this manner; these should be supported on light frames inclined at an angle of 45°, and Potatos, Peas, and similar vegetables could be arranged in plates in front of them.

The committee awarded a First-Class Certificate to a new yellow, early-flowering *Chrysanthemum* named "D. W. Thomson," raised by Mr. ALEX. THOMSON, Nurseryman, Dean Gar-

dens, Edinburgh; a Cultural Certificate was given to Mr. W. WILSON, Prestonfield Nursery, Edinburgh, for plants of *Neprolepis Scottii* and *N. Piersonii elegantissima*; and a Commendation to a number of seedling *Caraotians* raised from border *Caraotians*, *Souvenir de la Malmaison* varieties from Mr. T. VALLANCE, Cardross, Meikle Perthshire.

The paper for the next meeting, on October 6, will be on "Insecticides: Sprays and Spraying," by Professor R. Stewart MacDougall, M.A., D.Sc., F.R.S.E., Edinburgh.

NATIONAL DAHLIA.

SEPTEMBER 3.—This year the annual exhibition of the National Dahlia Society was held at the Horticultural Hall, Vincent Square. The change from the Crystal Palace cannot be declared a great success, for the number of visitors was few, although this may have been partly due to the very wet weather conditions. There was, however, a good display of all types of the flowers, and the exhibition itself was quite equal to any that has preceded it; the entries numbered more than 300, which represents about 60 more than at last year's show, but some intending exhibitors failed at the last minute, which is only to be expected when the weather conditions of the past fortnight are taken into account. The quality of the show Dahlias was not quite so good as is usual, for although the 1st prize exhibit, shown by Mr. WALKER, left little to be desired, the remaining stands were poor in comparison. Among the Cactus section, the blooms appeared quite equal to those of ordinary seasons, and it was a matter of comment that the flowers showed so fine after having had to withstand one of the severest autumnal gales for many years. With the Cactus blooms Messrs. JAMES STREEDWICK & SON again met with remarkable success. For the seventh time they won in the Silver Challenge Cup class, the varieties being all of their own raising, and ten of them were new this year. This firm won the cup outright for the second time. The amateur section was generally well represented, and some of the blooms were quite equal to those noticed in the professional classes. The greatest competition was seen in this section, there being, in some instances, as many as ten or a dozen exhibits in a class. Novelties were very plentiful, and amongst these the committee selected ten for certificates. A new break was seen in *Una*, a pink-coloured variety, in which the florets are very narrow, and are divided at the tips, forming a kind of cresting.

SHOW AND FANCY DAHLIAS.

In the largest class for show Dahlias, that for 48 blooms of distinct varieties, there were three exhibitors, Mr. J. WALKER, Thame, winning easily. The other contestants were Mr. W. TRESSEDER, Cardiff, and Mr. S. MORTIMER, Rowledge, Farnham, Surrey. Mr. TRESSEDER was awarded the 2nd prize. In the 1st prize exhibit the varieties were W. Girdlestone (a magnificent flower), Blush Gem, Colonel, S. Mortimer (a large, shapely bloom), Mrs. J. Greaves, Mrs. Rawlings, Golden Gem (of excellent form), Wm. Keith, Marjorie, Mrs. Rawlings, Graculus, Arthur Obeck (a fine bloom), F. Tranter, Chieftain (a big, bold bloom), T. Pendred, H. Clark, R. Dean, J. T. West, Eclipse (finely coloured), Lord Salisbury, Shirley Hibberd, E. Button (a delicate soft pink colour), Purple Prince, H. Turner, Dante, Rothesay, Duke of Fife, R. T. Rawlings, Dandy, T. J. Saltmarsh, the Reverend, Gooday, A. M. Burnie, Golden Fleece, Victor, Mrs. Fryer, D. Cornish, J. Walker, Dr. Keves (grand specimen), Maestri, Duchess of York, M. Stanton, J. Nicholson, J. Bennett, H. Keith, J. C. Vaughan, A. Rawlings, and Harbridge (a fine bloom of delicate colour). Messrs. TRESSEDER had choice specimens of J. Gooday, Richard Dean, Mr. Chamberlain, Sidney Humphries, James Cocker, Florence Tranter, Wm. Keith, W. Powell, T. S. Ware, and George Hobbs.

In the smaller class for 24 blooms of distinct varieties there were also three exhibitors, but neither of them showed anything remarkable, the quality of the flowers being only mediocre. The 1st prize was won by Mr. CHARLES TURNER, Slough, who had moderately good examples of Mr. Glascock, Colonel, Mrs. Langtry, Arthur

Oocok, Seraph, T. W. Girdlestone, Gracchus, William Keith, J. T. West, Standard, R. J. Rawlings, Hon. Mrs. Wyndham, John Standish, Marjorie, Harry Keith, Harrison Weir, Merlin, Shottesham Hero, Arthur Rawlings, Harbinger, John Hickling, Nansen, Mrs. Gladstone, and Posamond. Mr. SEALE had very choice blooms of Mr. Glasscock and George Gordon.

FANCY DAHLIAS.

There were two classes for fancy Dahlias, one for 18 blooms, distinct, and the other for 12 blooms. There was not a lot of competition; two growers only staged in the larger class, and four in the one for a dozen blooms. Mr. J. WALKER, Thame, won easily in the class for 18 blooms, his competitor being Mr. Wm. TRESENER, who was awarded the 2nd prize. The following are the names of Mr. WALKER'S varieties: T. W. Girdlestone, Wm. Sheldon, Erin Pasha, Mrs. Mortimer, Plutarch, Mrs. Saunders, Goldsmith, S. Mortimer, Rev. Camm, Dandy, Prince Henry, Duchess of Albany, Christie, Miss Browning, Comedian, L. Eckford, E. Boston, and Matthew Campbell. Mr. TRESENER had well-coloured blooms, and although small they were of good shape. His best were John Cooper, Mrs. John Downie, Rebecca, and J. Britton.

The premier stand of 12 varieties was shown by Mr. S. MORTIMER, Farnham, Surrey, and he was followed by Messrs. KEYNES, WILLIAMS & Co., Mr. CHARLES TURNER, Slough, being 3rd. Mr. MORTIMER'S best blooms were: Dazzler, Frederick Hunt, Miss Mortimer, Salamander (a fine bloom), Prof. Fawcett, Plutarch, Hugh Austin, and Mr. N. Hall. In the 2nd prize group were noted of good blooms of Rev. J. B. Camm, Dorothy, Gaiety, and Watchman.

SHOW AND FANCY DAHLIAS INTERMIXED.

There was a class for 12 blooms of these, but the response was poor, only two exhibitors showing. This lack of competition was perhaps partly because those who exhibited in the preceding classes were not allowed to enter in this one. The winning blooms were shown by Messrs. JOSEPH CHEAL & SONS, Crawley, and they were as follows: T. W. Girdlestone, Gracchus, Geo. Gordon, Erin Pasha, Dr. Keynes, Diadem, Florence Franter, R. T. Rawlings, the Reverend, Maud Fellows, Mrs. Saunders, and Dorothy.

CACTUS DAHLIAS.

The most important class for Cactus Dahlias was that in which a Silver Challenge Cup was offered. This is held by the winner for one year, and becomes the property of an exhibitor who wins it three consecutive times. As stated, Messrs. JAMES STREDEWICK & SONS won the trophy outright this year, and, in addition, the bunch of C. E. Wilkins in this group was adjudged the best in the whole of the nurserymen's classes, thus winning a Silver Medal offered for the best bunch of Cactus blooms. Messrs. STREDEWICK showed Diadem (dark red), Snowstorm (white), Samaria (purple, with magenta tips), Rev. T. W. Jamieson (pink, with yellow base), Evening Star (salmon-red, flowers with yellow base), Indomitable (bold, large rose-pink flowers), Diadem (rose-pink, with very incurving florets), Satisfaction (rose and white), Herald (pale pink), Mrs. Alfred Dyer (white suffused with rose), J. B. Riding (bronze with yellow centre), Harold Peerman (velvety), Verania (apricot), C. E. Wilkins, Wm. Marshall, Dr. G. Gray (scarlet), Rev. Arthur Bridge, and Rev. A. Hall.

The first-named ten are new kinds, never before shown on an exhibition table.

The 2nd prize was won by Messrs. JAMES BURRELL & Co., with very creditable examples of William Marshall, Artemis (reddish), Crescent, Ruby Grinstead, Mrs. F. Grinstead (a very fine variety), Paradise (yellow), Echo and Nelson (a fine shade of pink).

In the smaller classes for twelve varieties, in bunches of six blooms, there were two exhibits, shown by Mr. MORTIMER and Mr. E. V. SWEET, Sevenoaks. Mr. MORTIMER had the Pilot, Adonis (red seedling), Premier (scarlet), White Lady (a good decorative variety), Alexander (maroon), &c.

The most pleasing class for Cactus Dahlias was that in which the blooms were staged in vases, and decorated with foliage and fruits of

other plants. There were three exhibits, and they occupied much space. Mr. M. V. SEALE showed the winning vases, but it was difficult to say which was the best, for all appeared about equal in merit. The other exhibitors were Messrs. JOSEPH CHEAL & SONS and Mr. CHARLES TURNER, Slough.

CACTUS DAHLIAS DISPLAYED ON BOARDS.

There were three exhibits in the class for 48 blooms, distinct, and the three growers contended very keenly. Messrs. J. BURRELL & Co. were awarded the 1st prize, Messrs. KEYNES, WILLIAMS & Co. the 2nd, the other exhibitor being Messrs. JAMES STREDEWICK & SONS.

We have not space to enumerate all the varieties, but give as a selection the following in the winning group:—Nelson, Wm. Marshall, T. A. Havemeyer, Ruby Grinstead, Nubian, Mercia, Etirna, Seraph, Crepuscule, Beryl, Caradoc, Burletta, Faunus, Lustre, Pearl, Sunset, Leda, Marner, Comedy, Rev. A. Hall, Fairy, Brigadier, Crescent, Rival, Cassandra, Flag of, Truce, Nobe, Mrs. Macmillan, Una, and Eveline.

In the smaller class for 24 blooms, distinct, Mr. M. V. SEALE beat all other competitors, but he was closely followed by Mr. TRESENER.

POMPOU DAHLIAS.

Class II was for 24 varieties of Pompon Dahlias in bunches of ten blooms each. Mr. CHARLES TURNER was the 1st prize winner, with an excellent lot, having superb specimens of 'Garland', 'Madame Fortia', 'Edith Bryant', 'Komulus', 'Adeleite', 'Tommy Keith', 'Donald', 'Bacchus', 'Zerlina', 'Enia', 'Hyperia', 'Queen of Whites', 'Cyril', 'Marietta', 'Blush Gem', 'Phyllis', 'Nessia', 'Jessica', 'Clarence', 'Sybil', 'Adela', 'Lufta', and 'Thora'. 2nd, Messrs. CHEAL & SONS, with Phyllis, Clarissa, Marietta, Galatea, Florence Daisy, &c. 3rd, Mr. M. V. SEALE.

For twelve varieties Messrs. J. BURRELL & Co. were 1st, their only competitor being Mr. JOHN WALKER, of Thame.

SINGLE DAHLIAS.

There was not much competition for these refined flowers, which, although so beautiful, appear to be less in evidence each year at the shows. Messrs. JOSEPH CHEAL & SONS won in the class for 24 varieties, while Mr. JOHN WALKER was the only exhibitor for 12 varieties. Mr. CHEAL had shapely flowers of Kitty, Bertha, Snowdrop, Betty, Miss Roberts, Columbine, Verania, Princess of Wales, Serita, Peggy, Brilliant, Fanny, and Eugi San.

AMATEUR CLASSES.

A silver challenge cup was offered in a class for 24 blooms of show or fancy Dahlias or the two types intermixed. Mr. TOM JONES, Walton, N. Wales, won the 1st prize, with an excellent exhibit; 2nd, Mr. SAUNDY COOPER, Chippingham; 3rd, THOMAS HOBBS, The Cedars, Downend, near Bristol. The best six blooms of Show Dahlias were shown by Mr. THOMAS HASKINS, Kingswell, near Bristol, and the best twelve blooms of Fancy Dahlias by Mr. A. P. BONNINGS, 43, Park Lane (Chippingham), while ten six blooms of these flowers, Mr. J. GIBSON, Park View Lane, Chippingham, was placed 1st.

The Silver Challenge Cup for nine varieties of Cactus Dahlias was taken by Mr. W. J. PEELERS, Hastings, who had a fine stand of blooms, especially fine being J. B. Riding; the six blooms received the Silver Medal as the best bunch of Cactus Dahlias in the amateurs' exhibits, Mrs. E. Grinstead, Wm. Marshall, G. Wilkins, and Ruby Grinstead; 2nd, Mr. J. STODOLSKY.

The Gold Badge offered by Messrs. Dobbie & Co., Rothsay, for 24 blooms, distinct, was won by Mr. JAMES BRVANT, Salisbury.

SINGLE DAHLIAS were best shown by Mr. A. BRIDGE, The Rectory, Worth, Crawley, and Mr. ERWIN MORLEY, Rosebank, Bournemouth.

There were numerous other classes in the amateur section and several were provided decorations and floral devices.

AWARDS TO NOVELTIES.

First-Certificate winners were awarded the following new Dahlias:—*Jasper*, a show variety of rose-magenta shade. *Tom Jones*, this variety, described in our last issue, received a Bronze

Medal and a Certificate on this occasion; both these were shown by Mr. S. MORTIMER. *Una*, a pink variety, with narrow florets that are fringed at the tips, shown by Messrs. J. BURRELL & Co. *Minima*, a plum or purple-coloured Pompon Cactus variety, also shown by Messrs. BURRELL. *Adela*, a white Pompon, shown by Mr. TURNER, Slough. *Mrs. W. Merry*, a reddish-coloured single variety, shown by Rev. S. S. PEARCE. *Zephyr*, a single, facing a magenta colour, with a purple ring next to the yellow stamens, shown by Messrs. JOSEPH CHEAL & SONS. *Rev. F. W. Jamieson*, a large Cactus flower of pale pink colour, fading to yellow at the base of the very curved florets. *Debutant*, a pale pink Cactus with a pale yellow base to the florets and white tips. *Snowdon*, a white flower of the Cactus type, with rather stiff florets. *Mrs. Alfred Dyer*, yellow florets, stained with palest pink at the ends; all these Cactus varieties were shown by Messrs. JAMES STREDEWICK & SONS.

NON-COMPETITIVE EXHIBITS of Dahlias were shown by Messrs. DOBBIE & Co., Rothsay (Gold Medal); Mr. J. T. WEST, Tower Hill, Brentwood (Silver-Gilt Medal); Messrs. H. CANNELL & SONS, Swanley (Silver Medal); Messrs. T. S. WARE, Ltd., Feltham (Silver Medal); Mr. J. E. KNIGHT, Wolverhampton (Silver Medal); and Mr. J. EMERSON, Grove Road Nursery, Walthamstow (Silver Medal).

Obituary.

THOMAS ACTON.—We regret to record the death of this gentleman at Kilmacurragh, Rathdrum, Co. Wicklow, Ireland. Deceased was the eldest son of Colonel William Acton, for some time M.P. for Co. Wicklow. He was a Justice of the Peace and a Deputy-Lieutenant for the County. For more than forty years he resided at Kilmacurragh, which is situated on rising ground three miles in a direct line from the sea, with a hill some 800 feet high above the house; the soil is a deep, rich loam, on granite and slate, and as the climate of that part of Co. Wicklow is very mild many plants which are not considered hardy in some districts flourish there. The gardens at Kilmacurragh are particularly rich in species of Rhododendron, of which there are very large specimens, including fine trees of R. lacteum, R. Delavayi, R. lanatum, R. Shepherdii, R. Keysii, R. salignum, R. lepidotum, R. scotsum, R. Wightii, R. cinnabarinum, and R. decorum. Amongst rare trees and shrubs in the collection may be mentioned splendid specimens of *Libocedrus tetragona*, *taxegothia conspicua*, *Athrotaxis cupressoides*, *A. laxifolia*, *A. selaginoides*, *Cupressus lusitanica*, *Tsuga Brunoniata*, *Tsuga japonica*, *Cunninghamia sinensis*, *Podocarpus chilina*, *Embolium coccineum*, probably the largest specimen in the British Isles, *Triacantharia lanceolata*, 20 feet high, *Laurelia aromatica*, and *Quercus lusitanica*. The demesne covers some 600 acres, and is beautifully wooded. Many tree lovers from all parts have spent an enjoyable day inspecting the gardens, for, although of a retiring nature, the late Mr. Acton extended a warm welcome to all who asked permission to visit his garden. Much of his success with reputedly difficult plants was due to the fact that, whenever possible, he purchased such specimens of each variety and planted them in different aspects in order to test their individual requirements. In order to acquire a knowledge of the conditions under which trees and plants grew in their native homes he took, in company with his sister, an extended voyage round the world. Mr. Acton was in his 83rd year, and was unmarried.

CATALOGUES RECEIVED.

BULBS.

CHARLES TURNER, The Royal Nurseries, Slough. D. G. PIERCE, 6, Waterloo Street, Glasgow. EDWARDS BROTHERS, 10, Dame Street, Dublin. D. H. SINGLARS, 10A, Cross Street, Aberdeen. BARR & SONS, 11-13, King Street, Covent Garden, London.

MISCELLANEOUS.

WM. FIELDS & SONS, Hitchin, Herts.—Vegetable, flower, and farm seeds. W. KNIGHT & SONS, Park Nurseries, Heathfield, Sussex. J. H. SINGLARS, 10A, Cross Street, Aberdeen. W. SIMONS & CO., Portland Street, Kilmacross—Flower roots.

MARKETS.

COVENT GARDEN, September 9.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the stock, the way in which they are selected, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

Flowers, &c.: Average Wholesale Prices.

Table listing various flowers and plants such as Asters, Bouvardia, Calla, Carnations, Chrysanthemums, Dahlias, Eucrasia, Gaillardia, Gardenias, Gladioli, Gypsophila, Lilium, and others with their respective prices.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing cut foliage and plants such as Adiantum, Asparagus, Aralia, Berberis, Ceanothus, and others with their respective prices.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing plants in pots and other items such as Ampelopsis, Aralia, Aucuba, Asparagus, and others with their respective prices.

Fruit: Average Wholesale Prices.

Table listing various fruits and nuts such as Apples, Nuts, Walnuts, Peaches, and others with their respective prices.

Vegetables: Average Wholesale Prices.

Table listing various vegetables such as Artichokes, Beans, Carrots, Cauliflowers, Cucumbers, and others with their respective prices.

REMARKS.—Prices for English Peaches and Nectarines are included to be found only on a shortage of best fruits.

AMERICAN WATER MELONS are arriving in quantities and are selling well; their quality is superb. Red Romanas are particularly fine. For this fruit, English ones are arriving in moderate quantities; the price for these has been as high as 10d. per lb. Indian Corn is now a regular supply, is 6d. being the average price per dozen bushels. Some good samples of Worcester Pearman Apples, packed in boxes of two dozen, sell readily at 2s. per box. English Tomatoes are inclined to be scarce. Trade generally quiet. E. H. R., Covent Garden, 11 Wednesday, September 9, 1908.

Growers of China Asters report that they have rarely done so well as they have this season. Prices in medium-sized blooms are plentiful, but flowers of the best quality are scarce. Prices for Carnations are inclined to advance, Liliums have also been making better prices, especially L. longiflorum. Supplies of Lily of the Valley are not excessive. Tuberoses are plentiful. Gardenias, Eucharis, and Gladioli Frenchies are all well supplied, but Stephanotis is a little scarce.

POT PLANTS. With Erica dracops vernalis already seen, also Solanums with fine trunks. Chrysanthemums have been selling fairly well. Some well-flowered Zonal Pelargoniums are seen, but Ivy-leaved and show varieties are now finished for the season. Liliums in pots are over-abundant, especially L. lanciflorum rubrum and L. l. album. Plants of Campanula isophylla alba and May are well flowered. There has been a rather better letter from Lyons, but supplies of them in all sizes are over-abundant. Palms, Aspidistras, Duccenas, and other foliage plants are numerous. Ferns, and other hardy shrubs, are noticed, also a variety of hardy climbers. A. H., Covent Garden, Wednesday, September 9, 1908.

ENQUIRY.

SOPHORA JAPONICA.—I shall be obliged if any reader will furnish me with the dimensions of any large trees now standing or existing within recent years of Sophora japonica. I am especially interested because of a fine tree now in full flower growing on the site of the old Botanic Garden at Cambridge. It is 65 feet 6 inches high, 79 feet through the head, and the trunk, 5 feet from the ground, is 11 feet in circumference, while at the ground level its buttresses occupy a circle of a little more than 19 feet. This tree does not flower every year, but it is flowering more profusely than for some seasons past. A few years ago the tree was struck by lightning, and a crack in the trunk was made. Externally, it is now perfectly repaired, though the line of new wood is quite evident. This, probably, is one of two trees referred to by Loudon in his Arbotum et Fructicum Britannicum, edited 1844, and it was then 50 feet high. A tree in the Jardin des Plantes, Paris, planted 100 years previously, he records was 64 feet high, and the diameter of the head 40 ft. No tree then referred to by Loudon was higher than this. At Kew there was a tree 50 feet high, and at Syon there was another 57 feet high. R. Irwin Lynch, Botanic Garden, Cambridge.

BEECH SHOOTS DYING. A. Z. S. The injury is caused by a mite, Eriophyes fagee. All twigs bearing infected shoots should be persistently removed and burned.

BEECH TREES: Beech. We do not suspect your soil lacks any constituent necessary for the trees, and if it did, you have so well dunged the land that the farmyard manure would supply all the elements necessary for plant growth. Of course, trees, like other plants, do better on some soils than on others, and Beech is generally regarded as favouring soils which contain chalk.

DOES D. The Book of British Ferns, by C. T. Drury, price 3s. 10d., tree by p. st. The work may be obtained from our publishing department.

CUCUMBER AND MELON LEAVES: M. K. B. The leaves are badly infested with red spider, which is present in myriads, and there are also numbers of aphides or green fly present. The atmosphere of the house has been kept much too dry; spray the plants copiously with water at intervals.

CYANIDING A PLANT STORE: J. H. The following proportions are for 1,000 feet unit.—For the destruction of all scale insects, mealy-bug, thrips, &c., on (Camellias, Gardenias, Stephanotis, Passifloras, Diplodendras, Palms, Plumbago, Euphorbias, Orchids, Fuchsias, Azaleas, greenhouse Rhododendras, Rose, hard-leaved Ferns, Ficus, and many other

COVENT GARDEN FLOWER MARKET.

The flowers and foliage seen in remainder of autumn, for foliage plants, plants in pots, also berries spray, the chief of which is Viburnum Opulus.

CUT FLOWERS.

Chrysanthemums from the open ground are not so damaged by the rough weather as might be expected.

subjects, when not actually making a new growth, in a temperature of 50° to 55°, 2 ounces sodium cyanide, 4 fluid ounces of sulphuric acid, and 12 fluid ounces of water, exposure 40 minutes, will be perfectly safe quantities to use. The foliage should be dry, but this is not imperative in the case of dormant plants. Orchids may be "cyanided" safely when the roots are not making growth on the outside of the baskets or in the air.

DRACÆNAS: *A. R.* If young free-growing stock is provided annually from cuttings taken from the old stock plants, and grown in a suitable temperature, insects do not, as a rule, attack the plants. Red spider usually appears on plants grown in a dry atmosphere. Syringe the leaves with some weak insecticide, placing the plants on their sides until they drain, and then rearranging them in their proper position. Sponging the leaves, although it takes longer, is the more effectual means.

FUCHSIA SEEDLING FOR SALE: *E. B. B.* We do not know of any firm who would be likely to purchase the stock. Insert an advertisement in one of the gardening papers.

GLOXINIA LEAF BROWNED: *J. F.* There is no disease present in the leaves; the injury is caused by mites. Spraying the plants with tobacco water every third day will destroy the pests.

GRAPE PRCS. PINCE: *R. H.* There is no disease present in either the berries or the foliage. The latter has been badly scorched, and the berries have failed to mature. Ventilate the house early in the morning so that all moisture is removed from the surface of the leaves before they are caught by the sun's rays.

LILY STEM WOOLLY: *E. A. G.* There is no disease present in the stems. The coating of hairs is due to some unknown physiological condition that causes the cells of the epidermis to grow out as hairs.

LOBELIA COMPACTA DYING: *W. A.* The plants are attacked by the well-known Lobelia pest, *Phoma devastatrix*. Remove and burn the diseased plants, and treat the soil with quicklime.

MELON DISEASED: *A. H., Chertsey.* The death of your plant was due to bacteriosis, which is frequently the cause of trouble in Melon culture. Unfortunately, no cure for the malady is known, and once the plants become attacked they very rarely recover. But you can take precautions against the spread of the disease by burning the old plants and sterilising the soil in which they were grown. Before growing Melons in the same house again, see that the structure is well cleansed and the walls washed. It will also be advisable to procure seeds from a fresh source.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable output, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time; they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe or nearly ripe specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to retransmit the following numbers.

FRUITS: *Cuthish*. Both fruits appear to be Benioli, although No. 2 fruit is not so good in flavour as No. 1.—*H. C. Coles*. 1, Waltham Abbey Seedling; 2 and 3, Cox's Orange Pippin; 4, Lane's Prince Albert; 5, Manx's Codling; 6, Peasgood's Nonsuch.—*W. Rightson*. 1, Cockle Pippin; 2, Newton Wonder; 3, not recognised; 4, Tower of Glamis; 5, Afriston; 6, Small's Admirable.—*W. K. Malster*.—*Reader*. The fruits are so immature and badly shaped that it is impossible to name them with certainty. If you will send the varieties as they mature we will endeavour to assist you in their naming.—*H. Berks*. 1, Warner's King; 2, not recognised; 3, Sturmer Pippin; 4, Bramley's Seedling; 5, Summer Strawberry; Pear decayed.—*B. Davy*. 1, Keswick Codlin; 2, not fully developed; 3, Lady Derby; *J. Brodie*. *Jargonelle*.—*Club*.

Transcendent.—*Fovwill*. 1, Frogmore Prolific; 2, Ked Astrachan; 3, Afriston.

PLANTS: *A. B. H. J.* Sedum Ewersii; 2, S. altissimum; 3, S. spurium; 4, Desmodium canadense; 5, Galium verum; 6, Linaria repens; 7, Campanula lactiflora.—*A. B., Buckingham*. 1, Populus balsamea; 2, Ulmus glabra; 3, Better specimen required, appears to be a species of Morus.—*W. D.* Kibes alpinum.—*A. J.* Acer Negundo.—*M. H.* 1, Campanula isophylla; 2, Polygonum species. Send when in flower.—*J. B.* Begonia discolor (syn. Evansiana).—*F. B.* *Doehstori*. 1, Aralia ciliolata; 2, Aralia Chaberti; 3, Aralia filicifolia; 4, Codium Johannis; 5, Eschyanthus speciosus; 6, Stapelia Hanburyana.—*T. I.* 1, Agracatum sulcatum; 2, Brassica vernicosa; 3, Onocidium flexuosum; 4, Epidendrum fragrans.—*T. K.* Zephyranthes tubispatha.—*J. F.* Lapeyrousa juncea.

NUPHAR AS A PEST: *J. R. Allen*. We know of no better method of eradicating this pest from a pond than raking out the root stocks. If you attempt to kill the plants by poison you will destroy other vegetation in the water, also the fish, and injure the wild fowl.

ODONTOGLOSSUM LEAVES DAMAGED: *W. L.* The disfiguration of the leaves is very common in Odontoglossums. The cause is some check to the growth of the plants, and which may be more or less temporary. Usually the plants are otherwise healthy. Insignificant ventrications, a too high temperature at night, excessive moisture condensing and falling on the plants, and puncture by aphides when the leaves are young, have been mentioned as contributing to such damage, but no definite cause has yet been found. Usually the trouble arises in plants not well grown, and therefore errors in cultivation should be looked for.

PEACH STONE SPLITTING: *S. K.* The splitting is not due to disease, but to a want of balance between the growth of the stone and the other parts of the fruits. Some varieties are more prone to splitting their stones than others. It generally results from excess of food and moisture in the soil. See reply to *E. G.* in the issue for August 22, p. 136. The neighbouring tree may be furnished with a totally different root system.

RED CURRANTS AND GOOSEBERRY SPIGOTS DYING: *E. A. S. & Co.* The Gooseberry bushes are attacked by the Gooseberry black-knot (*Ploewrightia ribesia*, Sacc.), closely related to *Ploewrightia moribosa*, Sacc., the widely distributed "black-knot" of Plum and Cherry trees in the United States and Canada. *P. ribesia* attacks the stem and larger branches of the Gooseberry and of Red and Black Currant bushes in this country, and it is not uncommon to find the disease in neglected gardens, more especially where Currant scale or aphides are present in quantity. The fungus is a wound-parasite, since spores placed on an unbroken surface produce no result, whereas infection follows when spores are placed in a minute wound in the bark. It seems probable that aphides or scale insects enable the fungus to gain an entrance to the living tissues of the plant, as in the case of Larch canker, Apple-tree canker, &c. The first indication of disease is the wilting and yellowing of the leaves, which fall quite early in the season. As a rule, a branch is not killed outright in the first season of the attack, but during the second year the leaf-buds remain in a half-opened condition and the branch dies owing to the presence of the fungus mycelium in the conducting vessels preventing the ascent of water in the branch. The fungus does not show itself externally until the branch is dead, or nearly so, when its fruiting bodies burst through the bark under the form of large elongated and transversely-grouped black warts. These warts are often quite numerous and give a blackened appearance to the branch. Spraying is of no avail in the case of this fungus, but on the first appearance of disease, indicated by wilting of the foliage, infected branches should be removed and burned. Bushes should be kept clear of aphides and Currant scale. These particulars are taken from the *Board of Agriculture and Fisheries's Leaflet No. 215*.

RHODODENDRON PINK PEARL: *T. C.* The leaves have been again examined by our mycologist, who reports that no fungus is present on them. The shining particles may be due to deposition from water. The big leaves were very dry when received, and when examined they showed no signs of disease; if a malady was present it had entirely disappeared. When forwarding leaves for examination, they should always be packed so as to arrive in a moist condition.

THE PEAR TREE SLUG WORM: *J. P.* This pest of Pear trees appears to be spreading, and we hear many complaints as to its damage to the trees. It is figured and described in the *Calendar of Garden Operations*, from which we extract the following:—The perfect insect (saw fly) appears early in the summer, and the eggs deposited by the female on the upper side of the leaves hatch in a few days. The larva is of bottle-green colour. After feeding for a few weeks upon the leaves, the slug worms go down into the soil around the trees, from which they emerge again as saw-flies.

The slug worms are covered with a thick slime. If quicklime or gas-lime be dusted over them they are able to throw it off by exuding from their skins another coating of slime, and shedding as it were the injurious matter. But they are not able to repeat the process many times, except a considerable interval be allowed between the dressings, and it is this fact that affords the gardener an opportunity of destroying them by such means. If the lime be dusted over the trees in such a manner that it will reach the saw worms, and the process be repeated very soon afterwards, the second dressing will kill them. Other good methods of destroying the pests include syringing the trees thoroughly with soap-suds, tobacco water, or lime water, using a peck of lime in about thirty gallons of water. Remembering also that as the caterpillars go into the ground, it will be useful to remove the surface soil in the autumn 3 inches deep, burn it, and top dress with fresh materials.

TOMATO DISEASE: *A. J. B.* We found no caterpillar in the box, but they are not responsible for the trouble. The fruits are attacked by the Spot disease. The spores of this fungus are supposed to gain an entrance to the fruit through minute cracks or punctures in the skin; therefore, the use of green stable manure, and of anything likely to produce cracking in the fruits, should be avoided. Over-watering has this effect. As a preventive, ventilate freely, exercise vigilance, and spray the plants at frequent intervals with potassium sulphide, prepared as follows:—Dissolve one ounce of potassium sulphide (liver of sulphur) in a quart of hot water; then make up to two and a half gallons with cold water. Feed the plants with manure water.—*F. H. T.* The foliage you send is spotted with the disease known as "Septoria apple." You will find much information on this complaint in our issue for August 15, page 121.

WEEPING TREES: *O. P. Q.* No satisfactory explanation can be given of this habit as yet; indeed, although we know something about the mechanism by which a shoot may grow upwards and a root downwards, we cannot tell why it is that these positions are taken up. The current so-called "explanations" are really no explanations at all.

WORKS ON ROSES: *F. E. S.* Your references are incomplete. The numbers of the *Gardeners' Chronicle* referred to are in stock, and can be had from our publishing department. Perhaps the late Mr. T. Laxton's sons, the Nursery, Bedford, may be able to help you. The address of M. S. Mottet is 7, à Verrières-lez-Bonissou (Seine-et-Oise).

AUTUMN EFFECT OF TREES AND SHRUBS.

ANY trees and shrubs produce beautiful autumnal effects in the garden, firstly, by their brightly-coloured fruits, and, secondly, by the brilliant tints assumed by their dying foliage. Some shrubs and trees produce both beautiful fruit and handsome foliage, but it will be simpler to treat them separately, so that it may be understood a plant has a double value when mentioned under both heads.

TREES AND SHRUBS WITH BRIGHTLY-COLOURED FRUITS.

The list of these is considerable, and I will describe some of the best of them in alphabetical order. The month of ripening given below is only approximate, as the date will vary according to the summer being cold and damp or warm and dry.

ALANTUS GLANDULOSA (Tree of Heaven).—This forms a tree 60 feet or more in height, the winged fruits being borne in large, terminal bunches. They are of a lovely vermilion, red, and orange colouring. A large tree is a very beautiful object in September and October, especially when lit up by the sun. The sexes are borne on separate trees.

ACTINIA.—A group of female plants of this shrub well-studded with berries forms a pleasing

object in the garden from February to April. The green-leaved variety *veta* is the best to plant for fruiting, as the small leaves allow the bright-scarlet berries to be seen to the best advantage, and, in addition, the plant has a neat, rounded habit. One male plant should be planted close to every six or eight female plants.

BERBERIS.—The majority of the Barberries ripen their fruits before the autumn, but from August to October, or even later, the native *B. vulgaris* produces its drooping racemes of orange-scarlet fruits. There are also varieties of our native species with black, purple, and white berries. *B. Thunbergii*, with coral-red, and *B. coccinea*, with red and yellow fruits, are also effective in the autumn.

CELANTRUS.—*C. articulatus* is a vigorous climbing and twining shrub from China and Japan and bears small, yellow berries which split open in October and November, displaying the shining scarlet seeds which contrast strongly with the golden-yellow colour of the inside of the fruit. *C. scandens* is a North American representative of the genus with orange-coloured, instead of scarlet berries.

COLUTEA (Bladder-Senna).—The fruits of the Coluteas consist of comparatively large, bladder-like pods, and they are freely produced. In August they are of a reddish hue, and they afterwards gradually dry, in which condition they hang until the turn of the year. The pods are not very showy, but rather curious and uncommon-looking.

COTONEASTER.—These handsome berry-bearing shrubs have been extensively planted during the past few years, and no garden can be considered complete without them. *C. frigidula* forms a tall shrub 10 feet or more in height, and produces clusters of scarlet berries persisting to nearly the end of the year. *C. rotundifolia* forms a round, spreading bush 4 feet or so high, and the shoots are covered with bright-red fruits in autumn, and they last throughout the winter. *C. Simonsii* is a tall, thin-growing shrub with scarlet berries borne from end to end of the graceful shoots. *C. horizontalis* has tiny, coral-red fruits, and *C. microphylla* crimson ones. Both are pretty, spreading plants, suitable for the rockery, or for training up a low wall. With the occasional exception of those of *C. Simonsii*, none of the berries of Cotoneasters are interfered with by birds.

CRATEGUS.—Practically all the Thorns bear fruits of ornamental value, and a good selection is comprised by the following:—*C. Crusgalli* (the Cocks-pur Thorn) and its varieties bear drooping clusters of scarlet or crimson haws, which last well into winter. *C. coccinea*, *C. macracantha*, and *C. mollis* have clusters of scarlet fruits, which are wonderfully bright while they last, but they soon fall. *C. cordata* (the Washington Thorn) bears bunches of orange-scarlet haws, each about the size of a small pea, which hang a long time if protected from birds. *C. orientalis*, and its var. *sanguinea*, have brilliant-red fruits, which persist for a considerable period. *C. punctata* and *C. pinnatifida* var. *major* bear large haws of a crimson shade. The Fire-Thorn (*Crataegus pyracantha*) with its bright-scarlet clusters of fruits is a well-known and deservedly popular evergreen for walls, but it is equally good when grown as a bush in the open.

EUONYMUS.—There is probably no other shrub that affords such a lovely display of fruit from October to December as does our native Spindle-tree (*E. europaeus*) when the bright-red fruits open to display the orange-coloured seeds within.

HIPPURIA RHAMNOIDES (the Sea-Buckthorn) bears bright-orange coloured berries in thick clusters on the stems. They persist until the turn of the year, unless damaged by severe frost. The plant is dioecious, therefore the female plant must be grown for the berries.

HOLLY.—The Hollies are too well known to need description, but attention may be drawn to *I. Aquilium* var. *balearica* and *I. Aqu. var. maderensis*, both of which bear larger and brighter berries than the type, and *I. Aqu. var. fructu luteo*, which bears bright-yellow fruits.

PERNETTYA.—These are dwarf, spreading shrubs rarely more than 2 to 3 feet high with shining, prickly leaves, and small, white flowers that are followed by round, red berries, which last from October to April. In *P. speciosa* the berries are crimson, and in *P. mucronata* they are scarlet. There are varieties with various coloured fruits, but the two mentioned are the best.

PYRUS.—This genus ranks with the Thorns in the abundance of species with brightly-coloured fruits, and of these the section *Aria* or White Beam Trees is perhaps the best. Of these, *P. lanata* (*Sorbus majestica*) holds the premier position, as it is covered in autumn with clusters of intense-scarlet, oval fruits, though the allied *P. decaisneana*, *P. vestita*, and some of the forms of the common White Beam Tree (*P. Aria*) are not much inferior to it in this respect. The *Malus* (Crab-Apple) section must not be omitted, such small trees as the Siberian Crab (*P. baccata*), which is laden with bright, cherry-red fruits; *P. Malus var. coccinea* with comparatively large, scarlet Crab-Apples; and the John Downe and Dartmouth Crabs being necessary in every garden for autumnal effect. The Mountain Ash (*P. Aucuparia*) is of no value for a show of fruits in autumn, as the berries are at their best in August, and they prove too attractive to birds, which eat them readily.

RUNUS.—The dense pyramidal, crimson fruits of *R. typhina* (the Sumach) are showy in autumn, as also are those of *R. glabra*, an allied species, but the Smoke-bush or Venetian Sumach (*R. Cotinus*) must not be overlooked, as, though the fruit is insignificant, yet the dense, fluffy heads on which the fruits are borne give the plant a distinct and attractive appearance.

ROSA.—To many who are not well acquainted with the species of *Rosa* it may seem out of place to mention them in connection with showy fruits, but a plant of *R. rugosa* is a beautiful picture in autumn when covered with its large, flattened, crimson-red hips. *R. tomentosa*, *R. mollis*, and *R. canina* (the Dog Rose) are also showy subjects when covered with their scarlet fruits, and are well worth a place in the wild-garden. *R. nutkana* and *R. carolina*, both natives of North America, form small bushes, and are laden in autumn with small scarlet hips.

SKIMMIA.—The two hardy species of *Skimmia* bear bright-scarlet fruits, but the best is *S. Fortunei*, a dwarf-growing species which fruits freely, and is very showy during the whole of the winter. *S. japonica* has larger foliage, and does not display its fruits so well as the preceding species. The male form of *S. japonica* is known in nurseries as *S. fragrans*, and the female as *S. oblata*. The form known as *S. Foremanni* is one of the best for a show of fruits.

SYMPHORICARIS.—The best of this genus is *S. racemosus* (the Snowberry), which is conspicuous from October to the New Year with its snow-white berries.

VITIS HETEROPHYLLA is a native of China and Japan, and, together with its var. *humulifolia*, is very handsome when covered with clusters of blue berries which, however, do not very closely resemble bunches of Grapes. They require a warm corner and not too rich a soil to induce them to fruit well.

TREES AND SHRUBS WITH BRIGHTLY-COLOURED FOLIAGE.

It is rather a difficult matter to say exactly what conditions of climate are necessary to ensure those brilliant tints in the foliage of deciduous trees and shrubs in autumn, which we unfortunately only see in certain years. Of course, there is a certain amount of colour every year, but occasionally we get a season in which the autumn tints are especially magnificent, though there may not have been anything noticeably different in the climatic conditions of the preceding summer. If I remember rightly, the

display for some weeks. *Quercus heterophylla* and *Q. palustris* (the Pin Oak) belong to the same section, but are rather less brightly coloured. The leaves of the Tulip-tree (*Liriodendron tulipifera*) turn to a bright, golden-yellow, as also do those of the various species of *Celtis* (the Nettle-trees). Some of the Birches also, notably *Betula corylifolia*, a little-known species from Japan, possesses leaves which turn to a lovely orange-yellow. The foliage of *Liquidambar styraciflua*, *Nyssa sylvatica* (the Tupelo), and *Parrotia persica* all turn to a brilliant bronzy-red. The Hickories are scarcely known in this country outside botanical gardens, but *Carya tomentosa* and *C. sulcata* are worth growing for the size of their leaves and the rich, golden-yellow tint they assume in autumn. The Norway Maple and the Red Maple (*Acer rubrum*) turns its leaves yellow in autumn, and *Acer saccharinum* (the Sugar Maple) to crimson and gold. *Crataegus pinnatifida* var. *major* as-

from North America turn to a brilliant crimson-scarlet, as also do *Amelanchier canadensis* and the little-known *Euonymus alatus*. The Sumachs are wonderful plants to colour their leaves in autumn, *Rhus typhina*, *R. glabra*, and the poisonous *R. Toxicodendron* turning to various orange-scarlet shades. *Rhus Cotinus* changes to bronzy-red and yellow, and the gem of all, *R. cotinoides*, turns to indescribably fine shades of crimson, scarlet, and gold. The foliage of *Berberis Thunbergii* assumes a rich, scarlet tint, as also do the leaves of *Azalea pontica* and some of the Ghent hybrid *Azaleas*. *Vaccinium corymbosum* and *V. pennsylvanicum* turn to a bright-claret colour, and the feathery *Spiraea Thunbergii* affords a lovely bronzy-red tint, which renders it as effective as flowers for decoration. Of the new or little-known shrubs *Fothergilla alnifolia* (bright red), *Disanthus cecidifolia* (crimson), *Viburnum alnifolium* (crimson), and *Pyrus arbutifolia* (red) can be recommended for autumn colouring.

There are a few climbers that are effective in autumn, of which *Ampelopsis Veitchii* and the Virginian Creeper are perhaps the best known with their crimson and scarlet autumn tints. The leaves of *Vitis Coccinea*, *V. Romanetii*, and *V. Thunbergii* also turn bright crimson in most seasons, though they are not always to be depended upon in this respect. *J. Clark, Bagshot, Surrey.*

NEW OR NOTEWORTHY PLANTS.

RODGERSIA TABULARIS.

OF all the species of *Rodgersia* in cultivation, the one shown at fig. 89 is the most distinct. Other well-known kinds include *R. podophylla* with digitate leaves, and *R. pinnata* with pinnate ones. In the plant under notice, however, the leaves are peltate, like those of *Saxifraga peltata*. *Rodgersia tabularis* is a native of Northern China and Korea, and is said to grow in dense masses amongst coarse vegetation, close to a lake or riverside. It flowered for the first time in this country at Kew in July of last year, plants having been raised from seeds obtained from the Imperial Botanic Garden of St. Petersburg in 1905. This year the specimens grew to a larger size. As a handsome foliage plant it is a welcome acquisition, the light green peltate leaves, each about 1 foot in diameter, being borne on stems 2 to 3 feet in height. The leaves are irregularly lobed, while the petioles are covered with stiff white hairs which are dark at the base. These hairs disappear to a great extent as the plant develops during the season. The flowering-stems grow about 3 feet high, and bear an arching panicle of white flowers. Seeds are freely produced, and as seedlings are easily raised, the plant should soon become plentiful in gardens, where it is eminently adapted for the waterside or bog-garden. In general appearance this *Rodgersia* resembles a *Saxifraga*, and has been placed in that extensive genus by some botanists, under the name of *S. tabularis*. Heavy, loamy soil seems to suit its requirements, but it must have plenty of moisture at the roots, and partial shade is also beneficial. *W. Z.*

ORCHID NOTES AND GLEANINGS.

ONCIDIUM SPILOPTERUM.

FLOWERS of a very pretty elegance of this charming species are sent by Mr. H. Haddon, gardener to J. J. Neale, Esq., Lynwood, Penarth. The form of the flower is elegant, and the colouring bright and attractive. The rather small sepals and petals are chocolate purple; the blade of the lip, tips of the side lobes, the face of the column and anther-cap are bright yellow; the large and prominently raised crest is bright purple, the wings of the column being purple and yellow and its reverse side dark

(Photograph by W. Irving.)

FIG. 89.—*RODGERSIA TABULARIS*: A NEW SPECIES FROM NORTHERN CHINA; FLOWERS WHITE.

autumn of 1900 was exceptionally remarkable in this respect, everything being more brilliantly coloured than has since then been the case. Generally speaking, a summer with plenty of sunshine and a good rainfall will be followed by good autumn tints, as in such seasons nothing becomes ripened before its time, and there is plenty of moisture at the right time, and consequently the foliage remains healthy and vigorous to the last.

Among the trees which can be relied upon for giving colour in autumn are the American Scarlet Oaks, such as *Quercus coccinea* and its variety splendens, the foliage of both of which turns to a lovely crimson-scarlet, that of the latter being especially rich and affording a fine

sumes a fine bronzy-crimson, which is practically constant every year. Among commoner trees the golden hue of the Black Italian and Lombardy Poplars, the crimson of the Wild Cherry, and the warm, golden-brown tints of the Beech are especially noticeable.

There are a great many shrubs with leaves that colour more or less every autumn, and chief amongst these are some of the so-called Japanese Maples, varieties of *Acer japonicum*, and *A. palmatum*. Of these, the foliage of *A. japonicum* var. *vitifolium*, *A. palmatum*, and *A. p. var. septemlobum* turns to rich crimson shades, while that of *A. p. var. septemlobum* elegans changes to a soft yellow colour. *Acer Ginnale* from Manchuria and *A. circinnatum*

claret. The species was introduced from Upper Paraguay in quantity in 1892, and named *O. Saintlegerianum* before its identity with *O. spilopterum* was determined. This *Oncidium* requires a cool intermediate house, the collector stating that in its native habitat it is at times subject to a few degrees of frost.

CATASETUM CLESIANUM.

OUR illustration (fig. 90) represents an inflorescence of *Catasetum Clesianum*, which was awarded a Botanical Certificate at the Royal Horticultural Society on August 18 last, when it was shown by Sir Trevor Lawrence, Bart., K.C.V.O. The species was imported from Brazil in 1892 by Messrs. Linden, of Brussels, and was described in the *Journal des Orchidées*, 1893, p. 267. *Catasetum Clesianum* bears greenish-yellow flowers, and belongs to the section *Pseudocatasetum*, which includes *C. discolor*, to which the species under notice is closely allied. It is characterised by the absence of the antennæ commonly present in this genus of Orchids. The function of these organs was closely studied by Charles Darwin, and his results have been confirmed and extended by subsequent investigators. As is well known, the flowers in this genus are trimorphic, being male, female, and hermaphrodite. The identity of the three forms (which were formerly regarded as different genera) was established by Lindley, and also by R. Schomburgk. The antennæ, in those species which possess them, are restricted to the male and hermaphrodite flowers, and their function is to serve as a mechanism connected with the forcible discharge of the pollinia. Probably the absence of the pollinia from the female flowers is connected with the corresponding loss of the antennæ. The pollinia, together with their stalks and attachment disc, form a structure which is arched, and held in a strained position, after the fashion of a steel rod bent like a bow between the thumb and finger. When an antennæ is touched, a stimulus is given which causes an instant loosening of the tissue that connects the disc with the rest of the column, and thus the whole structure straightens suddenly and flies from its attachment to stick on to the body of the insect which has touched the antennæ while searching for nutriment in the flower.

CATASETUMS AT KEW.
